Bob is promising a media announcement of the results achieved with this procedure in the near future, which should make it easier for you to find doctors interested in this approach to dealing with AIDS and other blood-carried problems. I gather that eliminating the HIV virus doesn't take very long, but the rebuilding of the T-cells can take around 90 days.

If you want to learn more about AIDS I suggest you read the books by Duesberg, Douglass, Batmangheldij, Comby, and Wallach. If you are more interested in misinformation, read your newspapers and watch TV. People *are* being saved, even from the last stages of AIDS.

Can the bioelectrifier also help people lose weight and regrow hair? Hey, get together with an interested doctor and you tell me. He doesn't have the electronic smarts to build the unit and you don't have his license to kill, so you need each other. Of course, that presupposes that you'll be able to find a doctor not totally indoctrinated with the semi-religious belief that AIDS is incurable.

My experience (and Bob's) with AIDS workers is that they get all upset over the prospect of a simple, inexpensive cure. I've had them scream at me in rage that AIDS is incurable, and then stalk away, just at the *suggestion* that this new approach should at least be tested.

But hey, with over 300,000 deaths yearly due to hospital error and negligence (according to a Nader study), what's a few thousand more deaths, right? Unless that's *you* being rolled into the hospital, of course. Well, the odds are about 10:1 that you're there because you haven't treated your body right, and the odds now are that the doctors aren't going to be a lot of help, but they and the hospital are going to make a ton of money. I served on the board of directors of our local hospital, so I've seen all this first hand.

The MFJ-9406 6m SSB Transceiver

6 meters: The adventure begins.

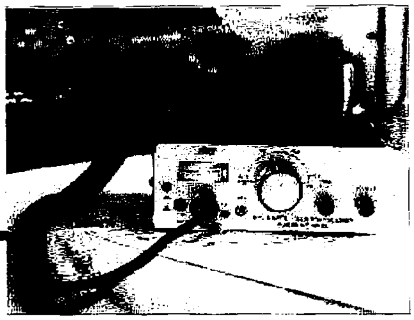

Photo A. The MFJ-9406. (Photo by Conard Murray WS4S.)

Jeff Gold AC4HF
1751 Dry Creek Rd.
Cookeville TN 38501

There are large numbers of new hams entering the hobby with the no-code Technician license. Unfortunately, most of these people are limited to experiencing only one small aspect of ham radio. Many seem to get on 2 meters and talk on repeaters. They are allowed to operate SSB and CW (phone and code), but may not be aware of how much more fun they can have. I believe that the more these people are exposed to other aspects of the hobby, the more they will be motivated to upgrade.

I've had a blast with the MFJ 20 meter SSB rig. It's small, portable, and works *great!* I have used it for the University Ham Club's QRP Expedition and during many SSB contests. When MFJ announced it was coming out with a 6 meter version, I had to have one. With great expectations, I waited for my new 6 meter rig to arrive. One of the best things about ham radio is trying different aspects of the hobby. I was eager to try 6 meters.

My new toy finally arrived. I opened the box and took out the rig, with its matching microphone (my MFJ 20 meter rig's matching mike worked super so I'd decided to get one with this rig). I found a spare spot on top of my operating bench, which in itself was a small miracle, then I looked around on the floor and found the appropriate DC plug to match the rig. I *very* carefully checked the voltage and polarity before plugging it into the new rig. I have a wide variety of DC plugs and alligator clips that allow me to get power to about any type of equipment. I remembered reading that my Gap vertical was resonant on 6 meters so I hooked it to the rig.

How do I sound?

I pushed the red power button and the rig instantly came to life. I turned the main tuning knob and picked up a signal. Using the smaller fine-tune knob, I tuned in the voice until it came out clearly. The rig has plenty of audio to drive the built-in speaker. I had the volume up only a little way and it was more than loud enough. I heard Jay KE4NYH calling CQ for some type of contest. I've worked my share of HF contests both on CW and SSB, but hadn't worked a VHF contest yet.

"This rig is about as simple to operate as it gets—it takes all of about five seconds to get used to it."

I answered Jay's call and he immediately came back to me. He told me some strange letter combination, "EM65," and I gave him my name, QTH, and his signal report. I stopped him before he could give the standard contest good-bye to ask for a detailed report on how the rig sounded.

"Sounds real good, real good audio quality," Jay said.

I explained that I was testing out a new rig and he was my first contact. He said, "Hope my rig sounds as good as yours does." This was high praise coming from someone on a full powered base station transceiver.

I later spoke with Jim WA4SOH, a veteran 6 meter operator. He gave me a 10 over 9 report. "Not too shabby for using low power on a vertical," Jim said. "Good audio. Yours is the first MFJ 6 meter I have heard. You're doing well—I'm impressed."

I talked to Jim for a long time about the rig, the way it sounded, and about the 6 meter band in general. Jim runs a Kenwood 690 with a five-element Yagi. He later told me, "If I didn't own this Kenwood I would purchase the MFJ."

Another opinion

I also talked with the local 6 meter guru Conard Murray WS4S. We talked for quite a while and he also was impressed with the way the rig sounded. He helped me while I played with the processor level. I then changed to my 160 meter dipole using a manual antenna tuner. The receive signal went way up and so did my signal report. Conard talked to me about using a beam on 6 meters. I plan on getting a loop or a beam to increase my effective signal strength, but meanwhile I am having a lot of fun with the 160 meter dipole.

Conard talked me into letting him test out the rig for a while.

"Overall, I was very impressed with the radio," Conard said. We discussed his impressions and findings. He found the rig to have good selectivity. "When you tune off a signal, it drops off and disappears. You can really separate out signals. The front end doesn't overload from very strong signals. The AGC (Automatic Gain Control) action on local signals is good. These signals sound natural and don't get distorted. The rig also has good sensitivity. If there is a signal in there, you should be able to hear it on this rig if you can hear it on a main station rig. It has good physical stability; you can bang on it, take it mobile or mountaintopping/portable and it

will handle the roughness. It makes an excellent starter rig for 6 meters and should be great for new or old hams. It also makes a fine portable rig and you should be able to run it for a good while off a gel cell."

Lots of assets

Operation is about as simple as it gets. There is an on/off push–button in the lower left corner, right under a combined S-Meter/Processor output meter. Next to the on/off button is the mike jack, then the transmit on LED. There is also a key jack for the optional Semi-QSK CW module that will be out soon (I can't wait to test it). There is a large tuning knob in the middle of the front panel, next to a smaller fine–tuning knob and an audio volume control. It takes all of about five seconds to get used to the rig.

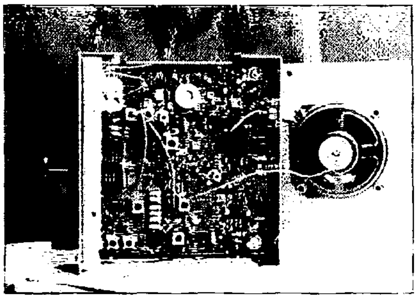

Photo B. Inside this 6m rig. (Photo by Conard Murray WS4S.)

"Plenty of audio to drive the built-in speaker—I had the volume up only a little way and it was more than loud enough."

On the back panel is the mike gain control, the 12-14 VDC power jack, and the SO-239 jack. There is also an external amplifier jack that uses a solid-state FET switch to key an amplifier, such as the Mirage A-1015-G.

The rig is small and rugged; it has low current drain and can operate on a D-cell NiCd pack or a small gel cell. Operating from the home, it will work with any 2A AC supply.

I didn't notice any drift after leaving the rig on for a while, and I was impressed with how natural the other operators sounded on it. The selectivity seemed good. It has a 2.3 kHz HF-style SSB ladder filter that reduces passband noise, helps to fight some of the QRM, and works on getting some of the weaker signals to come through and be understood.

The transmitter puts out 10 watts PEP. It has a Constant Current™ syllabic speech processor that MFJ claims gives an added 4-6 dB advantage to help cut through noise. I'm not one to dwell on technical specifications, but rather on how well things actually work. The 20 meter MFJ rig and this one both do *very* well with the amount of power put out, so I guess I believe that the processor works. I have had operators who were working high-rate HF contests stop and tell me how good the 20 meter version sounded.

The 6 meter band seems to have a personality all its own. There are times when it is totally quiet; other times you can work good distances with very low power. I think this new MFJ rig is a terrific way to try out a new band without investing a fortune. I am very pleased with it. 73

Manufacturer's Specifications

Receiver Station

Frequency coverage: 50.000-50.3000 MHz
Receiver type: Single–conversion superhet
Frequency control: Heterodyne VF, low–side injection
IF frequency: 10 MHz
IF selectivity: -6 dB @ 2.5 kHz
AGC: Audio–derived, 70–dB dynamic range
Sensitivity: .15 µV for 12 dB S/N
Audio: 1 watt into 8 ohms at 10% THD
Average Rx current: 60 mA (S-meter lamp disabled)

Transmitter Section

RF power output: 10 watts PEP
VSWR tolerance 3:1 VSWR maximum
Peak Tx current: 2.0A
Speech enhancement: RF compression, syllabic rate
Spurious attenuation: 60 dB
CW generation: 600 Hz tone (with optional installed)
Mike input: 600 ohms dynamic

Carr's Corner

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

This month we're going to take a look at some recently-announced ham products, and answer a question or two from the mail bag. First the stuff:

Ameritron AL-800H amplifier

It seems that there is another pair of "loudenboomers" on the market (**Photo A**). A recent news release from MFJ Enterprises, Inc. [P.O. Box 494, Mississippi State, MS 39762; (voice) 601-323-5869; (FAX) 601-323-6551] announced the Ameritron AL-800H linear amplifier for the high frequency ham bands. It is rated at what MFJ calls "1,500 watts plus."

The list price is $2,295, which, given the price of everything else these days isn't terribly bad (you ought to see the price of the "645" medium format camera I recently looked at—errr...pined over—it makes the AL-800H look cheap).

There are actually two models of the AL-800 amplifier. The straight AL-800 uses a single Eimac 3CX800A7 power amplifier tube, and runs to powers up to 1,250 watts. The addition of the "H" suffix, to make the model number AL-800H, means that the amplifier uses a pair of Eimac 3CX800A7 power amplifier tubes, at powers of 1,500-watts-plus. The AL-800 and AL-800H are designed for legal operation over the range of 160 meter and 10 meter bands.

The AL-800/AL-800H feature a tuned input circuit, output network, tube protection (those Eimac 3CX800A7 power amplifier tubes are pricey!), Automatic Load Control (ALC), vernier reduction drives for tuning, a

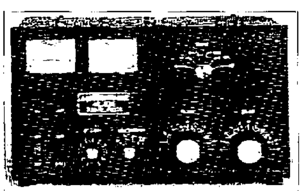

Photo A. The AL-800/AL-800H linear amplifier.

heavy-duty power supply (particularly important in power amplifiers), and a Step-Start Inrush Protection™ program (means longer life for those expensive bottles).

The tuned input circuit is an adjustable slug-tuned input circuit, which is common practice on HF linear amplifiers. The output network is the π/π-L design, which is claimed to provide smoother tuning and a wide impedance matching range.

The AL-800/AL-800H also have a grid circuit that limits grid current and thereby protects the tubes. Again, the Eimac 3CX800A7 power amplifier tubes are a major contributor to the price tag of linear amplifiers, so any protection is well warranted (grid current violations are major murderers of RF power tubes—I whacked my share of 6146B, 807, 1625, 813 and an occasional 4-400A in my misspent youth when I didn't understand grid current and overdrive!).

"Grid current violations are major murderers of RF power tubes"

The illuminated front-panel meters use the popular cross-needle design. These meters read peak forward power, reflected power, VSWR, high voltage, grid current and DC plate current.

The power supply of these linear amplifiers can be set for operation over 90 to 140 VAC, or 200-250 VAC; 14 settings of the AC primary voltage are possible. My own prejudice, by the way, calls for operation of kilowatt-and-up RF power amplifiers from the 220-VAC line. It requires a special outlet (of the sort that electric clothes dryers use, but not necessarily as many amperes (my linear amplifier is connected to a 220-VAC 20-ampere line that is dedicated to only the linear amplifier).

For information, call MFJ (as above), or Ameritron (116 Willow Road, Starkville MS 39759) directly at (601) 323-8211, or order direct at 1-800-647-1800.

Cross-Needle SWR/ Wattmeters

The other product line we'll look at this month is also from MFJ Enterprises, Inc. These products are RF wattmeter/VSWR meter units (**Photo B**). These units cover 1.8-60 MHz, 144 MHz and 440 MHz, for a price as low as $69.95. The MFJ-864 features separate HF and VHF/UHF directional couplers (the heart of most such meters), and each is equipped with its own SO-239 RF connectors. It has two power ranges, 30/300 watts forward, and 6/60 watts reflected. The MFJ-862 is a VHF/UHF version with the same power ranges, while the MFJ-860 covers on the 1.8 to 60 MHz bands.

MFJ offers their "one year no matter what" warranty on these units—given what some guys do to VSWR meters, that's pretty generous!

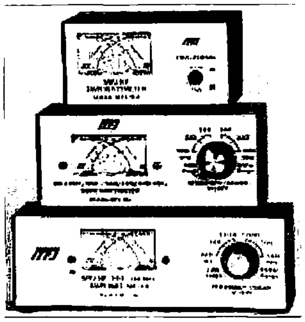

Photo B. MFJ-800-series RF wattmeter/VSWR meters.

Now for the nonsense

First, let me state flatly that I only respond to polite businesslike letters. The guy who, in December 1995, told me that my ancestry was suspect because I am a ham operator, didn't receive a reply...he's the same one who enlightened me with the blurb "...a 'ham' is half a pig's (yes, you know the word)." Sorry, dude, no cigar!

And the rest of the mailbag

I received two delayed letters on my series on vertical antennas. One of them asked whether the dimensions are the same for a ground-mounted quarter-wavelength vertical antenna as for a vertical antenna mounted on a tall pipe. The answer is: Not usually. As with so many things about antennas, the answer is a tentative "maybe yes, maybe no." I've put up a lot of verticals over the years: some of them were store-bought and some of them were homebrew. I've noticed that a slight variation in lengths is necessary, depending on where the antenna is mounted. I suspect that interaction with the local environment is the cause. But I've also noticed that the difference isn't always too great, and the resultant VSWR can be "tuned out" with a decent tuner. Still, install the vertical so you can adjust the lengths until the thing works right (Hint: Don't tighten the metal clamps until you finish adjusting it).

The other mailbag question about verticals arrived by Internet (see address below). The reader asked the value of the feed point impedance of the vertical. Again, the answer is a tentative "maybe...." The nominal impedance is 37 ohms (or as one purist chastised me, 36.6 ohms), and is therefore not a bad match for 52-ohm coaxial cable. But real verticals—you know, those messy things that we really have to put into or onto the air—are different. The feed point impedance will vary from a few ohms (like 2-3) up to the maximum. As a result, some companies offer multi-impedance broadband RF transformers that will help you match the actual impedance to 52-ohm coaxial cable. I've used the Palomar Engineers transformers, and have built 9:1 and 16:1 transformers following the directions given in the *ARRL Antenna Handbook*.

I've received several nice letters and E-mail messages on the twin-lead antenna discussed here a few months ago (and yes, the ends of the twin-lead *are* shorted!). Unfortunately, I didn't invent the antenna and can't take credit for it. I saw one for the first time in the late 1950s, late one night (actually, in the wee hours

of the morning) when a bunch of young hams went over to see a radio engineer from "Voice of America" who had just gone off duty. He told me that he'd found it in Bill Orr's (W6SAI) *Radio Handbook*. Bill, by the way, was my hero when I was a lot younger, and was the ham writer I most wanted to be like.

Connections...

I can be reached at P.O. Box 1099, Falls Church VA 22041, or via Internet E-mail at carrjj@aol.com. I am always glad to receive comments and requests, and will answer as many letters as I have time for...and that usually means all of them.

Staten Island NY 10313-0006

"Young Ham of the Year"

In the spring of 1990, an event took place which was to be a highlight of my teaching career, as well as being a highlight in a student's life. Mary Alestra KB2IGG, a seventh grader at the time, won the "Young Ham of The Year" award.

"Mary's love of radio was obvious, and her dedication to helping other children was impressive."

Mary was one of the most articulate young adults who had ever come through my amateur radio program. Her love of radio was obvious, and her dedication to helping other children was impressive. She seemed like the perfect choice to nominate for the award. The entire school took pride in her nomination. You can imagine how excited we all were when Mary was notified that she had won.

When a youngster receives national recognition, it has a big impact on his or her life. As you read about the qualifications for this award think about deserving young people you might want to nominate.

The "Young Ham of The Year" Award program was conceived in 1985 by then *Westlink Report* newsletter Editor-in-Chief Bill Pasternak WA6ITF. His desire was (and still is) to highlight the accomplishments of the nation's many young radio hobbyists, and to encourage the involvement of more young people in the exciting, rewarding hobby of amateur radio.

Corporate underwriting for this award program is traditionally supplied by Yaesu U.S.A. Corporation and *CQ Magazine*. This year the youngster who is chosen as 1996 "Young Ham of The Year" will get the chance to know what it's like to train to become an astronaut. The winner will be treated to Spacecamp in Huntsville, Alabama, in addition to other prizes supplied by Yaesu U.S.A. and *Newsline*. *CQ* publisher Richard Ross K2MGA says, "As we enter our second year as co-sponsor of this award program, we are expanding our participation to include a week at Spacecamp. Our nation has a growing need for well-trained scientists and engineers; even if they don't become astronauts, the Spacecamp experience can help young people get started towards technical careers."

The young winner will also receive an expense-paid trip to the Huntsville Hamfest, where the award plaque will be presented at the Grand Banquet, along with a special prize in the form of ham radio equipment. The trip and the radio are courtesy of Yaesu, and the plaque is provided by *Newsline*.

The "Young Ham of The Year" award is presented annually to a United States licensed ham who is 18 years of age or younger and who has provided outstanding service to the nation, his/her community, or the betterment of the state of the art in communications through amateur radio.

All nominations must be submitted before June 30, 1996, on an official application form. Applications are available by sending a self-addressed stamped envelope to: The 1996 "Young Ham of The Year" Award c/o *Newsline*, 28197 Robin Avenue, Saugus, California 91350. The nominating applications are also available for electronic download from several sites that provide *Newsline* materials over the World Wide Web and from the general interest ham radio files area on America On Line (AOL Ham Radio Club BBS-Software Exchange-General Interest Files).

Bill and I agree that the real spirit of this wonderful award is to highlight a young person who has done more than just pass a license exam. We're always on the lookout for the young adult dedicated to the fellowship and service that is vital to the preservation of amateur radio. Good luck with your nominations.

For more information contact: Bill Pasternak (805) 296-7180.

Make a MICOR Into a Repeater

A simple modification using a popular mobile radio.

Adrian Brookes VE3RHK
220 Hunt Club Road
Ottawa, Ontario
Canada K1V 1C1
ambrookes@aol.com

After our club had a few repeater failures we ended up using two Kenwood mobile rigs as the repeater, one as the receiver and the other as the transmitter. Ham mobile rigs can do just fine as repeaters in a quiet RF environment with a good duplexer, but mobile rigs aren't really designed for heavy-duty repeater applications or for use at a high RF level repeater site. We were looking for replacement equipment when we spotted an ad by Versatel Communications in this magazine. They were advertising $99 Motorola MICOR 45 watt mobile radios which could be converted into repeaters, so we called for further information.

I talked with Versatel's head technician and everything sounded pretty good, so we took the plunge. To save time, and since we didn't have a Motorola test set handy, we ordered the radio with crystals installed and tuned, the repeater conversion instruction manual, and a conversion parts kit. All we would have to do were a few minor wiring modifications. The total cost with our options and shipping was less than $200.

The radio arrived in a month, with all items as advertised. After reading the instructions through a couple of times, we were ready to begin surgery. The modifications required were: (1) modifying the receiver RF connection; (2) strapping the receiver and transmitter channel selection (the control head would normally do this); (3) adding a small perf board with a couple of pots to act as a substitute volume and squelch control (again, the control head would normally do this); (4) minor modifications to the radio's power switching circuitry to allow full duplex operation; (5) interface to a controller (bringing the mike, PTT, receiver audio and COS signals out via a cable or connector).

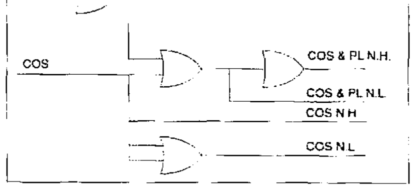

Fig. 1. The CMOS gate wiring.

"The transmitter strip is well-suited for ham repeater operation, as the whole transmitter side of the radio is an extruded heat sink."

Photo A shows the mobile rig with the top cover removed, as viewed from the rear. As you can see, it is assembled with modules; the transmitter strip is on the left side, the interface and connector board is the narrow strip in the center, and the receiver is on the right side. Each module has an RF shield (except for the one which we removed during modification of the audio/squelch board and lost). The SO-239 bulkhead connectors, Cinch-Jones power connector, and DB-9 controller interface connector are our modifications on the rear panel.

The transmitter strip is well-suited for ham repeater operation, as the whole transmitter side of the radio is an extruded heat sink. Although the transmitter is rated at 45 watts, we planned to run only about 25 watts, so there should be plenty of margin for repeater duty, especially when adding an external cooling fan as we have done.

Since the radio is a mobile unit, it normally switches the antenna connection between receiver and transmitter through a relay. Part of the conversion to make the radio full duplex is bringing out the transmitter and receiver antenna connections to individual connectors. Versatel's instructions call for the receiver RF connection to be brought to the rear panel, with the transmitter still using the existing relay for the transmitter connection (which is at the front of the radio).

Photo B shows the bottom of the radio viewed from the front. We made some changes in Versatel's suggested wiring. This photo shows that our modifications brought out both the receiver and transmitter antenna connections to the rear panel, along with the power and controller interface connectors. The radio's original antenna connection can be seen at the very left front of the radio, with the key lock just to the right of the connector. We disconnected the DC wiring to the antenna relay to save a little power, since the relay is now unused. To bring out the transmitter connection you will need an RCA jack and a piece of coax (RG-58 or similar) appropriate for the transmitter power level. Unscrew the output filter assembly located at the front top of the transmitter strip (it's labeled TFD6101A in the lower left-hand corner, in **Photo B**) to route the cable and RCA plug to the transmitter output jack, then reconnect the filter.

The radio we received had some

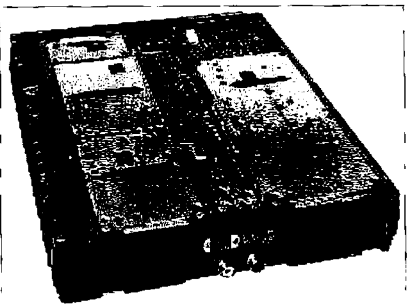

Photo A. Top cover removed.

surface corrosion along the rear panel. This was not unexpected for something that may have spent the last 10 or 15 years in the trunk of a taxi cab or a truck. A little sandblasting and paint made the panel look like new. We then used a punch to form the RF bulkhead connector holes, and a nibbler tool to make the openings for the power connector and DB-9 connector.

The modifications, suggested by Versatel, also call for an audio/squelch pot board to be installed in the radio; normally a control head would provide these functions. In **Photo A** you can see the small piece of perf board and the components at the far top end, mounted with double-sided tape to the radio's interconnection board. Also, a speaker load resistor is visible slightly to the right of the perf board. **Photo C** shows the detail of these two items. In **Photo B**, a small Radio Shack™ speaker is double-sided taped to a metal divider inside the audio/squelch compartment.

Versatel's instruction manual shows the COS signal to the repeater controller being picked from their "Point H" (pin 12 of the audio/squelch board connector), but this is the output of an analog detector and is not a clean logic signal. I recommend taking the COS from pin 10 of IC202. The instruction manual supplied by Versatel is good from a modular level, but there is not enough detail for this mod to be made unless you have a complete manual. For those who don't have and can't find one, IC202 is one of only two chips on the audio/squelch board, and it is the one located closest to the interface connector pins. Pin 10 of IC202 is also routed to pin 8 of the interface connector pins, and our wiring to that pin can be seen in **Photo C**. The COS signal at this point is 0 volts unsquelched and 6.9 volts squelched.

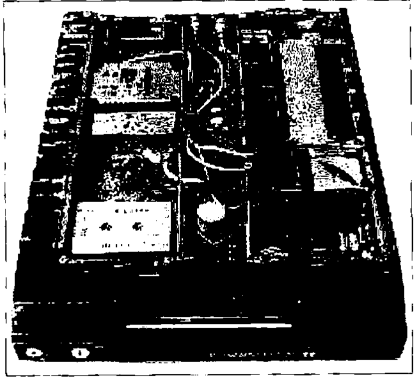

Photo B. And here's the bottom. The messy part is our added wiring.

In addition to bringing the COS signal out to the controller interface connector, we also added a Motorola PL (CTCSS) decoder, and routed the PL decoder detector output along with the COS signal to a CMOS 4001 gate. The gate is wired as shown in **Fig. 1**, and provides us with the ability on the interface connector to use any of three squelch signals for the controller: COS only, PL only, or COS and PL ANDed from the 4001. And, with the single 4001 chip, any squelch signal can be either normally high or low.

Why would we use PL and COS ANDed? This radio uses resonant reeds to detect the CTCSS signal. These reeds have both a start-up decode delay time and a shutdown delay time. By anding the PL and COS, the shutdown delay time is eliminated from the composite signal.

Photo D shows the 4001 attached with double-sided tape and the nest of wires attached to it. Pin 7 of the chip is bent over and soldered to the small lug rising through the PC board, and pin 14 is folded over and soldered to the trace marked as REG+ on the board. The PL decoder output is picked off from pin 3 of the PL board, which would be the third in-line pin closest to the audio amplifier connections of the audio/squelch board. If you have the PL board, you'll know where to connect from this.

Alternate wiring

You can order these radios with a control head and cable. All of the modifications except RF cable routing and duplex power switching can be performed inside the control head, or you can discard the control head and just use

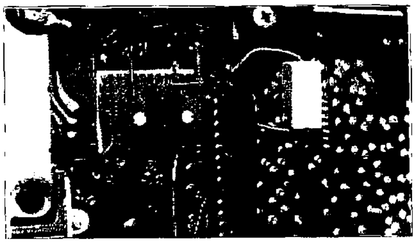

Photo C. The audio/squelch board we added. This is normally in the control head.

the appropriate wires from the control head's cable for controller interfacing.

If your controller requires switched audio, then you could accomplish this several ways. The COS from where we took it provides a clean logic level which can be used to drive an analog gate or (gulp!) a relay. The Motorola audio/squelch board in the MICOR includes squelch driven shunt switches inside IC202 that could also be used to ground the low level audio. A full manual would be handy for this mod.

Summary

What we got from Versatel was exactly as advertised. The rig was crystalled and tuned and the instructions were simple and clear. The radio has worked fine from its first day of installation.

On the downside, the included schematics are a little hard to read in some places, and a better copier or non-reduced copy from Versatel would help. It would also be nice to have more schematics of the circuitry itself. Then again, if we looked hard enough we could probably get a manual from a local radio shop.

Overall, we would rate Versatel's conversion package an eight out of 10. The Motorola MICOR mobile makes a great repeater, and for a couple of hundred bucks, you just can't go wrong. If you have a MICOR from another source, Versatel will also sell the conversion instructions alone. 73

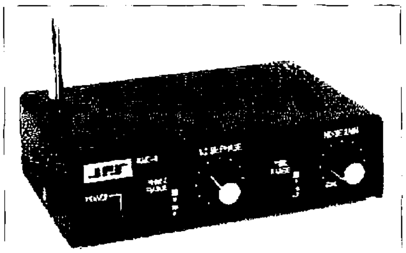
The ANC-4 Antenna Noise Canceller from JPS

Reduce that noise!



Pete Ferrand WB2QLL
65 Atherton Avenue
Nashua NH 03060-1904
pferrand@scoot.netis.com

The use of phasing to get rid of noise is common with microphones. The ANC-4 uses the phasing technique to get rid of noise before it gets to the antenna input of your radio. It's not an audio filter or a digital signal processor. The ANC-4 is connected between your normal antenna and your transceiver or receiver. Thus, when the ANC-4 knocks out noise, the noise never gets into your radio, so the receiving circuits have less to do and aren't overwhelmed by all that noise. The ANC-4 does its phasing by using a separate antenna to pick up the noise; that signal cancels out the noise you're listening to from your regular antenna.

First, set up the ANC-4 so the noise is picked up at the same or greater level from its noise antenna as it is with your regular antenna. Second, adjust the ANC-4's phasing controls until the noise disappears. If the noise doesn't null out, use the "phase range" and "freq range" buttons to increase the range of the phase shifter network.

The "gain" and "phase" controls interact some, so it's a good idea to watch the radio's S-meter closely and set the radio AGC to "fast." It's not a hair-trigger adjustment and the noise null increases smoothly as you approach the correct point. Settings will normally not need to be changed as you tune across the band, but they will need to be changed if the noise changes.

"I was able to get 40 dB of noise reduction on computers, broken streetlights, and power line noise."

How does it work? Simple—the noise signals from both antennas are combined. Your adjustments have caused these two signals to have equal amplitude and opposite polarity (a 180-degree phase difference). Some types of noise are easier to cancel than others. The unit is designed to deal with locally generated noise, since all noises present constantly changing phase relationships when propagated over a distance.

The other requirement is that the noise antenna must hear the noise. The ANC-4 is provided with a telescoping whip, which works fine for most power line and computer noises you may have around the house. If the noise that bothers you can't be heard on the whip, there's a phono plug in the rear for attaching another antenna which can be positioned so it does pick up the noise. This may be a wire run into the engine compartment, if you're trying to defeat mobile ignition noise, or an outside dipole with polarization adjustable to match the noise, or perhaps a wire running parallel to your shack's power lines.

I was able to get 40 dB of noise reduction on computers, broken streetlights, and power line noise—including line noise hereabouts that sometimes wipes out an FM broadcast station a mile away. It also works on household stuff like light dimmers, microwave ovens, and TV set horizontal oscillators. By careful operation, it's also possible to null local radio transmitters, such as broadcast stations.

You can't get rid of any signal subject to multiple modes of propagation. That basically means signals beyond ground wave. I discovered that some local noises change. For instance, a video monitor's signal can be perfectly nulled, only to have the noise reappear when the image on the monitor changes. You can only null one single noise at a time. I found that getting rid of the loudest noise source makes it easier to hear other noises! Discouraging, but that's life and those noises were there screwing up my listening pleasure anyway. Of course, I could get a second ANC-4...

Other features include an internal switch that bypasses the unit automatically when you transmit through it, so you can use it with a transceiver as long as it puts out 150 watts PEP or less. If you use a linear, simply locate the ANC-4 in the antenna line between the linear and transceiver. Lastly, by using just the noise amp and the whip, with no main antenna, you can use it as an active antenna.

My conclusion is that the ANC-4 is definitely worth having if you have noise problems. It is not a replacement for an audio filter or a DSP unit—absolutely not. To deal with heterodynes, band noise, static crashes, and adjacent signal splatter you need DSP and audio filtering.

The times I'm most grateful for the ANC-4 are when I'm listening to my receiver, something starts up down the street and the S-meter swings over 20 over 9...a few adjustments to the ANC-4 and I can hear the station again. The ANC-4 ($176 retail) is manufactured by JPS Communications, P.O. Box 97757, Raleigh NC 27624. Telephone (919) 790-1048, (800) 533-3819 or FAX (919) 790-1456.

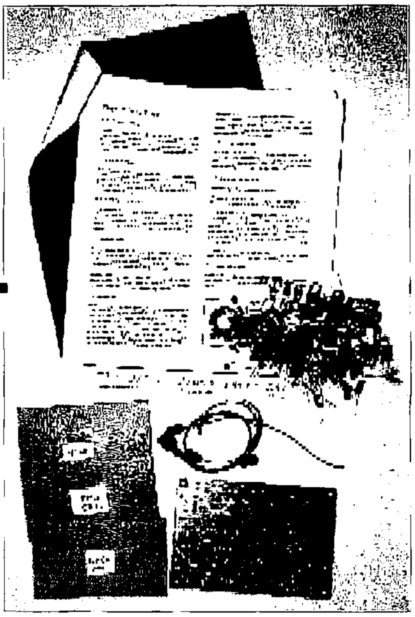
The Green Mountain GM-20 QRP

Another small wonder!

Marshall G. Emm AAØXI/VK5FN
2460 S. Moline Way
Aurora CO 80014



One of the attractions of QRP operation (5 watts of RF power or less) is the wealth of excellent equipment that is available in kit form, at reasonable prices. The latest super rig may have more bells and whistles than the theater organ at Radio City Music Hall, but it will cost as much as a large car or a small house. Meanwhile, if you are prepared to avoid causing QRM and TVI and accept the challenge and excitement of QRP operating, there are some excellent single-band CW transceiver kits available for less than $100!

A steady stream of new QRP kit rigs has appeared over the last few years, so when a new one is announced by one of the Godfathers of QRP design, it gets a lot of attention. Such is the case with Dave Benson's (NN1G) new Green Mountain single-band CW transceivers for 40, 30, 20, 17, and 15 meters.

The Green Mountain series is a "lateral descendent" of the Small Wonder (or "40-40") series and the NN1G Mark III ('95 *ARRL Handbook*) transceivers. The main distinguishing feature in the new line is a separate heterodyne local oscillator, which adds a bit of complexity, but really helps on the higher bands. The transmitter drive has been beefed up with an MMIC embedded in the bandpass filter, providing 12 dB gain to the driver, and the final output is adjustable from 0.5W to a solid 3W. In the 20 meter version, the second harmonic is down 34 dB and spurs are down about 50 dB, at full power. Now that's *clean!*

The rig also features full break-in (QSK) via the familiar FET switch popularized by W7EL, and the receiver has incremental tuning (RIT) via a quad analog switching IC. A four-pole crystal filter on the 8 MHz IF sets the received bandwidth at 700-800 Hz.

Apart from the separate LO section, the receiver and audio output sections are pretty much standard for QRP rigs, but with an MC1350 IF amp providing 30 dB gain and a high level of stability. Sensitivity is right up there with the big rigs; minimum detectable signal is quoted at .1 μV (-126 dBm), and, in practice, you're limited to the ambient atmospheric RF noise level. These are *hot* little receivers!

> ***"The instructions for winding the 13 toroids, often a real bugbear for kit builders, are some of the best I've seen."***

It's available as a board kit (printed circuit board, all board-mounted parts, and instruction manual) for $75 postpaid, so you get the fun of building a well-designed kit which, after an hour or so, you'll turn into a real fun machine.

Construction

Your first pleasant surprise comes when you open the package from Small Wonder. The board is nicely done, double-sided and solder-masked, and the components are all new and of high quality. Several small groups of components are packaged in separate envelopes to avoid confusion, and the manual is a pleasure to read.

Small Wonder's philosophy is to encourage you to understand what you are doing. The manual includes a detailed description of the circuit components and trouble-shooting instructions, but it does assume a reasonable level of skill on your part. You don't get step-by-step Heathkit-like instructions telling you how to identify a 2.2k resistor and where to put it; the instruction steps are things like, "Install all of the board mounted components for the Local Oscillator as per the diagram below," or, "Wind and install all of the toroids in accordance with Table 1." For most of us, that's plenty. The silk-screened parts overlay on the circuit board and the parts list are all you should need and you can do it in whatever order suits you. However, the tips shown in the sidebar may be helpful and the instructions for winding the *13* toroids, often a real bugbear for kit builders, are some of the best I've seen.

An interesting approach is to have you build, test, and partially align the heterodyne local oscillator stage first. RF voltages are measured with an oscilloscope, but if you don't have one you can open the supplied "test circuit" envelope and build yourself an RF probe for your digital voltmeter. Getting this stage built and aligned insures that you are on the right track with your soldering techniques, and gives you a known starting point for the final testing and alignment.

This is a board kit, but turning the finished board into a finished rig in a box isn't difficult. All off-board connections (except a short link of coaxial cable for the antenna) are made via pin connectors. The wiring harness, with mating connectors already wired and color-coded, is provided in the kit.

Alignment and testing

You'll need some additional components in order to wire up the board for alignment and testing. They're available at your local Radio Shack™ or from any mail order parts house. and should set you back about 10 to 15 dollars. not counting the box:

- 10k gain pot (audio taper)
- 100k main tuning pot
- 5k RIT pot
- SPST RIT switch
- Key jack (RCA or 1/4")
- Headphone jack (2.5mm or 1/4", your choice)
- Antenna jack (SO239 or BNC)
- A power connector (and .75A fuse)

I used a combination audio gain pot and power switch, and connected a power-on LED. I also used a DPDT switch for the RIT so I could switch 12V to an RIT-on LED. For power, I run red and black wires through a grommeted hole to a Molex-type connector (RS 274-222) via an in-line fuse holder (in the positive line). It's a good idea to wire everything up on the bench so you can test and align the rig before locking it up in a box. The use of the wiring connectors makes this very easy to do.

The alignment is relatively straightforward and you will need only two or three items of test equipment: a general coverage receiver, an HF transceiver, and some means of measuring power output. My rig came into alignment very easily, and went right to the rated output of 3 watts. The sidetone is a sampling of the RF output, so its pitch is a direct representation of the transmit offset and there is no adjustment necessary. The VFO range turned out to be approximately 85 kHz, down a bit from the rated 100 kHz, but within the tolerance of the varicap.

The GM-20 on air

The first thing you discover when you take your GM-20 into the real world is that the receiver is *sensitive*. It is every bit as sensitive as the big rigs and has adequate selectivity. The filter skirts are steep, and although you may prefer a narrower bandwidth, you can usually use the RIT to throw an unwanted signal out of the passband. A variable bandwidth filter would be nice, but there are enough inexpensive external audio filter kits around so that it really isn't necessary.

The keying is clean and precise, and the sidetone is pleasant to listen to. There is no apparent drift, and the QSK function is very smooth.

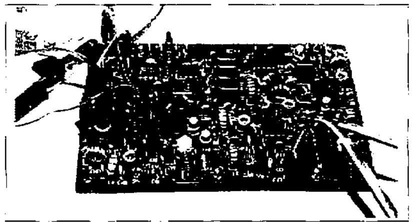
It's always a thrill to make that first QSO with a new rig, especially when the other station is on the other side of the continent, also running QRP, and gives you a good signal report. Say what you like about solar minima, but there is some real truth in the QRPer's motto: "Skill, not power!"

Conclusion

The Green Mountain series represents a terrific value for the money, and the rigs are great fun to use. Watch out—QRP is addictive! It's probably not a good kit for a beginner, but if you have at least intermediate kit building skills you will find that it's easy, and you will have the added benefit of knowing that you really built something!

The Green Mountain transceiver kits comprising circuit board and all board-mounted components are available from: Small Wonder Labs, 80 E. Robbins Ave., Newington CT 06111; (203)-667-3536.

Note from the Big Cheese: *If you build one of these rigs please let me know what fun you've had with it after a few days on the air. I want to know, and if you've made any really interesting contacts, the readers will be interested too. Wayne*



Tricks of the Trade

(1) Never buy a kit from someone who doesn't offer to fix it if you are unable to get it going.

(2) Read the manual! They all say that, but it's surprising how often a problem could have been avoided if you had just read through the darn book first. Those corrections at the end of the manual can cause a lot of grief.

(3) If a copy of the circuit board layout is not provided in the manual, *make* one. Just photocopy the board, both sides. The copy of the component side is useful if component labeling is covered up by the components. A copy of the foil (soldering) side will be invaluable if you have to track down solder bridges; often it is impossible to see whether two points should be connected without referring to the artwork or a photocopy.

(4) If the foil (soldering) side of the board is dirty, or if you got your fingerprints on it while you were photocopying it, clean it with alcohol before you start soldering.

(5) Sort the components and check them off against the parts list before you start soldering. If you find a wrong or missing component, you may be able to get it replaced before you need it, or at least minimize the delay.

(6) If you have any doubts about your soldering skills, do some practice work with junk components and then get a local ham to check your work.

(7) Solder under a magnifying glass. A magnifying desk lamp is the best bet, but a "helping hands" device with a magnifier will do.

(8) Check *every* joint under magnification *as you do it*. Be especially careful to watch for solder flowing onto adjacent tracks or pads.

(9) Keep some desoldering braid handy and fix those mistakes immediately. Don't make a mental note to come back and correct later.

(10) Do no more than 5 or 6 components at a time. Where two component leads share a solder pad, do them both at the same time so you don't solder over an empty hole. Often there is a good reason for the order shown in the manual.

(11) There are two exceptions, regardless of what the manual says: (A) Do the IC sockets first. If nothing else is on the board you can just turn it over and solder without worrying about holding the things in place. (B) Do the toroids next. These are often problem spots, and if nothing else is on the board you can easily use your multimeter to check continuity between the pads, insuring a good joint and continuous coil.

(12) In general, do the smaller components (and those that mount flat to the board) first; larger ones last. Otherwise you may have trouble getting to the holes.

(13) Once you have finished mounting board components, clean the excess flux from the foil side of the board using a commercial flux remover or acetone (be sure to do this in a well-ventilated area and heed the precautions on the solvent container). A clean board is *much* easier to troubleshoot. Look over the joints and reheat any that do not look right.

(14) Before applying power for the first time, double-check that all components are in the right places and have the correct polarity. If you are too lazy to check everything, at *least* check all diodes, electrolytic capacitors, and integrated circuit chips.

(15) When you first apply power, look carefully for any signs of smoke! You may be able to detect a hot spot or a component turning brown in time to disconnect the power and find the problem. If you can, you might also hook an ammeter in series with your power supply so if the meter shows more current than expected you can turn the power off!

(16) Bench-wire all external controls and connectors so that you can test and align *before* you get the circuit board screwed down in a box.

(17) If you do have to send it back, ask for a description of what was wrong with it so you can avoid that problem next time.

The Carolina Bug Katcher Multiband HF Mobile Antenna

Jeff Gold AC4HF
1751 Dry Creek Road
Cookeville TN 38501

Any mobile antenna is a compromise. I wanted one that would allow me to operate on several bands, but without my having to carry around resonators for each band. One that fit the bill was the Carolina Bug Katcher by Lakeview, the makers of the Ham Stick single-band antennas.

The Bug Katcher sells for $89.50, which makes it one of the least expensive multiband mobile antennas. It provides continuous coverage of all amateur, Mars, and marine bands from 7 to 31 MHz. The Hi Q coil gives 1 to 2 S-unit improvement over the Ham Stick's. The antenna is 7.5 feet long and stores in a 50-inch-long space.

Setup

To set up the antenna I put little clips on the coil and then used an MFJ Antenna Analyzer to measure the SWR for each band I wanted to set up (see **Table 1**). Once I had the bands set up it was a matter of just switching a quick disconnect clip from one of these set points to another to change bands. Yes, I have to get out of the car, but it only takes a few seconds to switch bands.

Fitting the antenna mount to the car was the most difficult part for me. The main function of the mount is to provide mechanical stability and support, since going down the road at 65 mph places a significant wind load on the antenna. The second function of the mount is to provide a good ground.

"I wanted a mobile antenna that would allow me to operate on several bands, but without the need for resonators for each band; the Carolina Bug Katcher fit the bill."

In today's automobiles you can't assume that a trunk lid or bumper is grounded, so it's a good idea to use an ohmmeter to check for a low resistance path (less than 25 ohms) between the grounded portion of the mount and the negative pole of your car battery. Or you can use a magnetic mount on the roof, which provides a nice ground plane effect.

Mobile antennas work best when they're high and in the clear. Some hams drill a hole in the car roof to mount the antenna. While this is probably the ideal installation, there are a few hams who are unwilling to drill holes in the roofs of their cars! I'm one of the latter, so I use the Lakeview Quad Magnet mount ($49.95) on my mini-van. I just stick it on the roof, thread the coax through the door, and I'm ready to go. I have to watch it going under low tree limbs and through parking garages. Although I have used this setup with the Bug Katcher, I feel a lot more comfortable using a heavy duty split ball mount. I used the one from Lakeview ($21.95 cat #075) on my other vehicle and haven't had any problems.

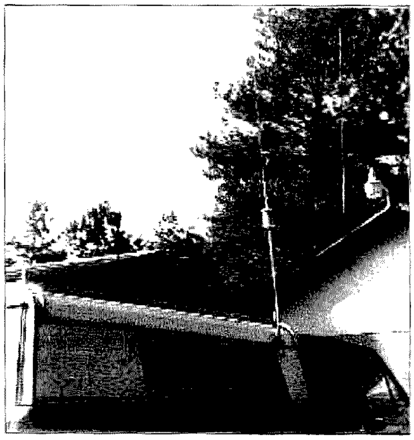

Photo A. The Carolina Bug Katcher mobile antenna from Lakeview Co.

Operation

After I finished setting up the Carolina Bug Katcher on my car, I turned on the rig and tuned around on 20 meters. I heard Dale WA7KYT operating a Special Events Station on the West Coast. He was a 57 and gave me a 55. Considering he was on a directional antenna and I was on a mobile antenna, I sure couldn't complain. I next talked to OE6T, who was working an SSB contest.Once again I didn't have any trouble at all making or maintaining contact. I have used the Bug Katcher on both CW and SSB with a great deal of success.

You can get more information from Lakeview Co., Inc., 3620-9A Whitehall Rd., Anderson SC 29624. Telephone (803) 226-6990 or FAX (803) 225-4565.

Economical High Current Power Supply

A "smart" battery charging system to build.

William Jacobs WA8YCG
Route 1, Box 212
Independence WV 26374

It was a dark and stormy night...well, it was. A blizzard caused a power failure, and it got very dark and very quiet very fast. The setup I use to keep the battery in my Field Day camper charged came in *very* handy—I was able to put my HF radio back on the air. In fact, it worked so well I now use it as a power supply.

With this circuit and a small 800 mA wall transformer, I've been able to forget maintenance on the battery over the winter. The battery (a regular auto battery, not a deep-cycle) is 4 years old and has not degraded appreciably.

Why it works

Most new transceivers use 12 volt direct current for operation. Getting the high current necessary for transmitter operation requires an expensive power supply. Here is a way to reduce this cost as much as possible.

Modern transceivers require 12 volts at 1 or 2 amps for receive operation. This is not a difficulty. A well filtered, well regulated 3 amp power supply will sell for less than $25 new from a radio supplier and even less, used, from a flea market. The high current problem starts when transmit operation begins. When in the transmit mode, current consumption of a 100-watt rig could exceed 20 amps. This high current demand lasts only a short time but it is real and must be serviced. Knowing how much power must be made available for transceiver operation can be analyzed in a limited manner.

Let's consider a CW QSO. The on/off operation of a CW signal produces a duty cycle of just a little more than 50%. Since transmit/receive is about even—we listen as much as we talk—this theoretical CW QSO is about 25% key-down transmit and 75% key-up receive. This would imply that the long-term (over the total QSO) current consumption of a CW transceiver requiring 20 amps key down will be only 5 amp hours for each hour of transmitting time and 1 or 2 amp hours for receive. The total would be 6.5 amp hours (25% of 20 + 75% of 2).

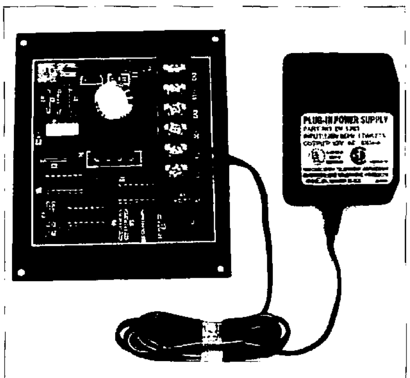

Photo A. The completed power supply unit. (Photo by John Jacobs, Independence WV 26374.)

When this transceiver is operated from an automobile, we supply high current from the auto storage battery and replace the power with the car's charging circuit. It is not necessary to have the charging system supply the high transmit current. It is entirely possible that with lights, air conditioner, fan, and windshield wipers on, the charging system will not be able to meet the demand. It will, however, be able to replace some of the energy used, little by little, as we motor down the highway. If this same type of operation could be used at home, the average current draw would be supplied by the much smaller, more economical power supply, and peak current would be supplied by a battery and a battery charging system.

How it works

A storage battery is used as a reserve for the high current operation requirement and is recharged with a small low cost, low current "smart" battery charging system that can be left on indefinitely without harming the battery.

> ***"It's a small low-cost, low-current 'smart' battery charging system that can be left on indefinitely without harming the battery."***

The project is built in five systems. The first system, "the smarts," senses battery voltage. The second, a logic circuit, provides switching signals. The third is an oscillator, used as an AC-to-DC converter. The fourth is the power FET or switch and the driving circuit, and the last is a power conditioning circuit.

The smarts of the charging system come from monitoring the battery voltage to keep the battery at or near full charge. The circuit operation is as follows. Battery voltage is divided by resistors R3, R4, and R7 and fed to comparator U3A and U3B. U3, an LM339, is a quad (four devices on one chip) voltage comparator. The output of comparator U3B is set to go low when battery voltage is above 13.5 to 14.0 volts. This voltage is the "Turn Off" signal of the charging system. When the battery

voltage reaches this point, charging ceases. The output of comparator U3A is set to go low when battery voltage is below 13.0 to 13.5 volts. This is the "Turn On" signal of the charging system. When the battery voltage is below this point, charging commences. When battery voltage is below "On," the system will be on and when the battery voltage is above "Off," the system will be off.

These two signals are connected to U1, a 4011, a quad 2 input NAND gate. U1A and U1B form the logic circuit. These two NAND gates latch the charging circuit on until the "Off" signal is reached and keep it off until the "On" signal is reached. This hysteresis of 1/2 to 1 volt keeps the circuit from turning on and off at microsecond rates. In normal operation, the charging circuit may stay off for as long as 20 seconds. In some cases, depending on battery age, capacity, and condition, it could look as if the battery voltage were being held at the "Turn On" voltage. Actually, the voltage rise of the battery is so fast that it looks like current is continuous. This can be verified with an oscilloscope. This will taper off in time. The switching action prolongs battery life by keeping the battery from gassing. Battery gassing is destructive to the battery and requires more maintenance. The output of the logic circuit (Drive) goes to an oscillator.

U2 is a 4047 IC oscillator with an operating frequency of about 2500 Hz. It is turned on with the signal from the logic circuit (Drive). It is used to make alternating current from direct current The alternating current is rectified and used to drive the gate of the power FET. The AC output of this oscillator is coupled to T1, a simple interstage transformer, through capacitor C2. The output of T1 is rectified and applied to the gate of Q1. This voltage has reference to the source terminal of Q1, and produces a positive 12 volts added to the battery voltage without regard to battery voltages. This high voltage (about 25 volts) feeds the gate of Q1 which connect the battery charging voltage to the battery. Q1 is a power field effect transistors that will have a very low resistance when turned on. The junction resistance of the transistor goes down markedly when the gate voltage is increased. However it must be kept lower than the breakdown voltage of the gate. On the specified transistor this is 20 volts. Even with the low resistance, the transistor may get warm and should be fastened to a heat sink if current of more than 2 or 3 amps is supplied. The power conditioner is a full-wave bridge rectifier, filter capacitor and regulator circuit.

Make it work

The circuit board makes construction very easy. All parts except the power transformer are mounted directly to the board. Construction time should average about one hour. Start with the resistors, capacitors (with the exception of the electrolytic capacitor), diodes (observe polarity), terminal strip, transformer, voltage regulator, the power FET, and all the ICs. Sockets for the ICs are not necessary and cost more than the ICs. The electrolytic capacitor is large and should be installed last.

The resistors in the voltage divider circuits were 1% precision resistors on the first few chargers that I built. I have found however, that the precision is not necessary. The range of the "Turn On/ Turn Off" voltages are not at all critical so the 1% precision resistors are not needed. I have since used 5% resistors and they work just fine. This no-adjustment approach removes lots of unnecessary fussing. The voltage "ON" and "OFF" values may be different from their intended values of 13.0 and 14.0 volts but the difference will be inconsequential to the operation of the power supply. As long as turn off is 14.2 volts or lower, and turn on is above 12.8 volts, appropriate operation will result.

Any power transformer with output of 12 volts AC will power the system. The bridge rectifier diode I specified is rated at only 4 amps and the capacitor has a working voltage of 25 volts. These are the limits placed on the transformer. I have found that a small wall transformer rated at 12 volts AC 800 mA will

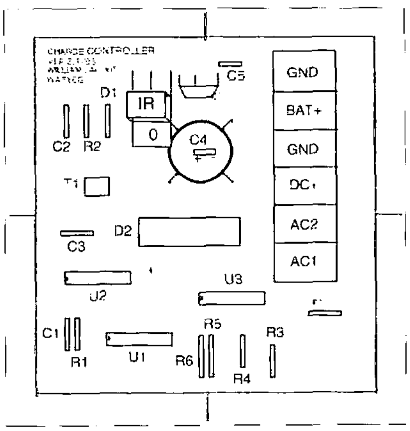

Fig. 2. Silk-screen pattern.

keep my 100-watt HF station running for more than 3 hours a night and be ready to go again the next night. A 3.5-amp wall charger would recharge the battery completely in about one hour for each hour of actual operation. Depending on the radio, the bigger transformer may cause some hum.

There are no blinky lights on this project. Intentionally. Operation can be checked with a voltmeter and once proper operation is verified, the power supply will be relegated to the floor under the table. No further thought will be given to it.

All that's left to do now is to connect a battery, rig, and the charge controller together and have fun. The use of a covered plastic marine battery box is recommended. If a scrap of wire should happen to come in contact with the

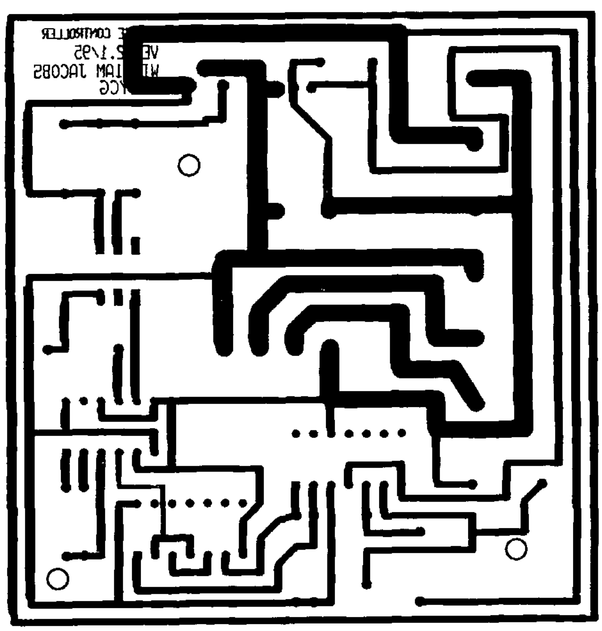

Fig 1. PC Pattern from the top of the board. When the board is printed, the text will be "correct reading."

battery terminals, the energy stored in the fully charged battery will be turned to heat—absolutely spectacular! Avoid it!

In operation the battery voltage will fluctuate between approximately 13.0 and 14.0 volts. This can be easily observed with a digital voltmeter. The voltage fluctuation may be hard to see on a 50-volt scale of an analog meter. It will, however, be easy to see the charge current switch on and off as the circuit maintains the full charge of the battery.

This circuit will also work with a solar panel. There is no blocking diode so the charger uses power all the time. The drain on the battery is about 10 mA. A good blocking diode would eliminate this. Before you add it, considering the following: The average night is 12 hours. 12 hours times 10 mA is 120 mA-hours. Charging at 1 amp the battery drain will be restored in 7.2 minutes. I feel it is better to lose the 10 mA than to limit the maximum charge by the diode-caused voltage drop. If your panel has more loss, you may want to use a diode between the panel and the charge controller.

I have built several of these circuits and have a printed circuit board. Friends have also built the circuit for about $20 plus the wall transformer. If my little project intrigues you and you want a board or all the parts drop me a line.

HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92633

Talking T's and Hidden Repeaters

"The T is on the air!" That announcement is sure to give an adrenaline surge to everyone at the starting point of a mobile hidden transmitter hunt. When you start out on a T-hunt, as these radio direction finding (RDF) contests are called, you never know where you'll end up and you don't know what you'll find there. No wonder most hams who try T-hunting get hooked on it.

With high-gain quads, Doppler sets, and other state-of-the-art RDF equipment that I have described in this column over the years, finding a hidden signal ought to be easy, right? Alas, T-hunting is far from an exact science. What's more, the hider is doing everything possible to foil you at every turn. That challenge is what makes it fun!

In a recent exchange of messages on a Usenet ham radio newsgroup, 20 T-hunters told of sneaky spots where hams have put hidden transmitters. A majority involved low-power unattended T's in unlikely places such as the hollow of a tree, the trunk of a police car, a baby carriage at the zoo, and suspended by a wire under a bridge. Christopher Greenhalgh N8WCT wrote, "It's fun sitting in your car, watching the guys run up to you with a big smile thinking they have won, only to say, 'You have to find the actual transmitter,' which you have stuffed in a bush about an eighth mile away, being watched through your side-view mirror."

Canned messages from canned T's

For stunts like these, you need a self-contained T package, ready to deposit at the hidden site and leave for the duration of the hunt. Ten years ago, hams made them with miniature tape recorders. Endless-loop cassettes designed for answering machines would repeat sound effects or short messages continuously, along with station identification.

The possibility that a T will get drenched by rain, heavy dew, or automatic sprinklers makes some sort of sealed enclosure a necessity. Military surplus ammunition cans are a popular choice because they are waterproof and will hold a handie-talkie, recorder, audio/timer board, and sealed lead-acid battery big enough to power the HT for several hours. Sometimes the hunt circumstances demand something even smaller. Two meter transmitter boards by Agrelo Engineering (see last February's "Homing In") are just right for occasions when you need a truly tiny T. That company also sells miniature digital voice recorder (DVR) boards that perform like a cassette recorder, but are stamp-sized and more reliable.

Agrelo Engineering has plenty of experience with digital voice technology. According to owner Ioe Agrelo N2OOC, "Our principal business comes from custom designs involving our DVR boards for clients around the world. They are great annunciators for product displays, vending machines, amusement parks, and museums."

N2OOC recommends his Micro 1.4 models (**Photo A**) for most hidden T applications. "This is a multi-message microprocessor-controlled recorder designed around the ISD2500 series voice recorder chip, using Direct Analog Storage Technology (DAST)," he says. "The voice messages are in EEPROM and need no battery backup for 100 years. This is not a computer voice synthesizer, but an actual digital audio recorder, so the sound is very natural. Its 'sleep' mode increases battery life. When standing by between messages, it shuts down power going to parts that are not being used."

A standard Micro 1.4 board will record and play up to 255 separate messages, totaling up to 90 seconds. It has an external trip terminal for each of the first four messages. A momentary ground on a trip pin causes the unit to wake up, play the entire message, then go back to sleep. While the message is playing, the on-board microcontroller holds a push-to-talk (PTT) output high or low (your choice) to key your hidden T. Holding a message pin grounded causes the unit to repeat (loop) that message continuously.

The loop mode is ideal when T-hunt rules require a continuous transmission. On the other hand, the ability to go to sleep makes the Micro 1.4 ideal for Ts that transmit infrequently. For example, the MMRA hunts in eastern Massachusetts are often difficult long-term events with transmissions only every five minutes or so. To take advantage of the sleep mode, you will need a simple external timer circuit to ground a message trip input when a transmission is scheduled. N2OOC says he plans to sell a circuit board for such a timer; it may be available by the time you read this.

The ISD2500 chip contains an on-board amplifier capable of putting 50 milliwatts of audio into a small speaker. You won't need that much audio to drive the mike input of your transmitter, but it might be useful for building decoy "audio bunnies" to spoof the hunters as they "sniff" on foot.

Two tiny push-buttons on the Micro 1.4 control all functions and programming. They double as Record/Play buttons and Menu/Sub-menu buttons. Once you have recorded your hidden T message using the supplied electret microphone, it will take some button-pushing to get into the Auto-Play mode and set the delay time. First command it into the Menu/Sub-menu mode, go to menu 2, 3, or 4 (for 10-60 seconds, 1-6 minutes, or 10-60 minutes delay, respectively), press Sub-menu the correct number of times for the delay you want (counting the number of LED flashes to be sure you did it right), then press both buttons to start the program. If power to the board is interrupted for any reason, your message is not lost but you must repeat the above sequence to get it into Auto-Play mode again.

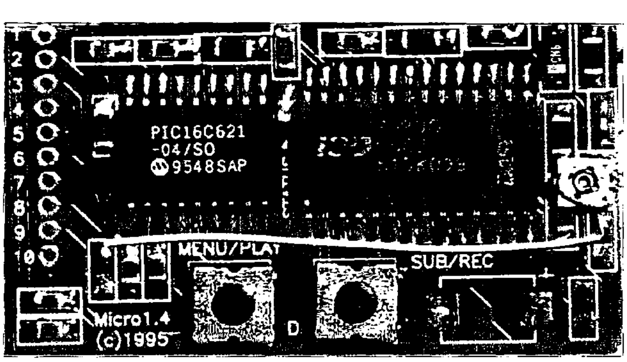

Photo A. The Micro 1.4 Digital Voice Recorder board measures only 1" x 1-7/8". This is the simplex repeater version, which gets all incoming audio from the repeating transceiver. An electret microphone is supplied with all other versions.

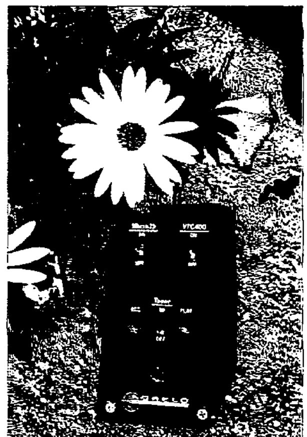

Photo B. This little hidden T has gotten a workout during practice sessions for on-foot foxhunts at Hamcon-95 and the West Coast VHF/UHF Conference. It contains a digital voice recorder, timer board, and 190-milliwatt transmitter, all sold by Agrelo Engineering. Four AAA alkaline batteries power it.

If you are concerned that accidental interruption of power during the hunt will upset the programming or if you want to avoid all the button-pushing during setup, you can have N2OOC make a custom "fox" version of the Micro 1.4 for you. When power is applied, it will come up in the Auto-Play mode. The transmission timing for such a custom unit is predetermined and cannot be changed in the field.

To illustrate how easily Agrelo microtransmitters and DVR boards go together to make a tiny T, N2OOC built one in a 4-3/8" x 2-1/2" x 1-1/4" plastic box (**Photo** B). "The label was made on Corel Draw and laser printed," he says. "Then clear packing tape was applied to the top and cut out. This is a great way to make your own labels."

The enclosure could have been much smaller; size was dictated by the need to have big enough batteries to power the T for the duration of a hunt. Switches should be relocated inside the box to prevent accidental movement. Agrelo Engineering sells two smaller Pactec ABS plastic enclosures (2.4 x 1.6 x 0.8 inches and 2.4 x 2.3 x 1.0 inches), but does not sell complete T's like this.

What's that echo?

Although you call your local .34/.94 machine a "repeater," it doesn't actually repeat what you say. It merely listens to you on one frequency and retransmits your audio in real time on another. On the other hand, your packet controller in the digipeater mode really is a repeater. It digitally "records" packet messages and "plays them back" on the same frequency a few seconds later. If a voice repeater did the same thing as a digipeater does, it would be a true simplex voice repeater.

A simplex voice repeater in a good location allows weak portable and mobile stations to hear one another's transmissions, just like a regular duplex repeater. Its only drawback is that users must wait for each transmission to be recorded and played back. On the other hand, a simplex voice repeater doesn't require a duplexer or multiple antennas because it operates on only one frequency and doesn't transmit while receiving. All that is needed is an ordinary transceiver, antenna, DVR, and some additional logic for control and timing. A complete simplex repeater system can fit in a briefcase, ready to deploy following an emergency.

Joe Agrelo says, "One day a good friend, George Chapek N2AIG, asked if we could turn our DVR into a simplex repeater for emergency preparedness. We did it, and now anyone can get one. Currently our first Simplex Repeater is being used by our local RACES group with great success."

The Agrelo Simplex Repeater board is a custom version of the Micro 1.4 DVR, with a different microcontroller. According to N2OOC, "The PIC16C620 has four analog inputs as comparators and voltage references. The DVR microphone input becomes the audio input from your receiver. The speaker output goes into the mike input of your transmitter. There are two PTT output lines, one high active and one low active.

"The intelligent squelch feature is accomplished by the microprocessor's analog input," Joe continues. "The audio threshold is about 1 volt peak-to-peak. When the processor detects incoming audio, it goes into the record mode. When there isn't any audio for more than four seconds, or if the DVR chip reaches overflow, the unit stops recording and goes into the playback mode."

Agrelo Engineering sells the Simplex Repeater board for the same price as other Micro 1.4 versions. Repeater functions are fixed in the unit's memory, so at power-up it performs a self-test, then goes into the Simplex Repeater mode automatically. The station ID message is in non-volatile memory. Because of the circuit differences, the Simplex Repeater version cannot be reprogrammed into the timed Auto-Play modes of the standard version.

What does all this have to do with T-hunting? Well, think how much fun a concealed simplex repeater would be as a hidden T!

> ***"A complete simplex repeater system can fit in a briefcase, ready to deploy following an emergency."***

Hunters would have to transmit to it in order for it to transmit to them. It would also mimic any other hidden Ts on the frequency. Of course, hunt rules would have to allow for such a device and all transmissions would have to be shorter than the repeater's maximum storage time.

I tested the Agrelo Simplex Repeater in March when WA6OPS, WB6UZZ, KE6IPY, and I hid for the Fullerton Radio Club's monthly Saturday night hunt. Rules require continuous transmissions so we used it as an optional second T, just for fun. When hunters found the main T on 146.565 MHz, a note instructed them to QSY to another simplex frequency and call us. It was then that they learned their transmissions were being delayed and repeated from an unknown location that they would have to find if they wished to have a bite to eat with the rest of the group. The hidden repeater was in our van in the parking lot of a restaurant, hooked to a beam pointed at the main T site a few miles away. Through it, we easily worked the hunters with our handie-talkies from inside the diner.

The Simplex Repeater performed quite well during my tests. Its intelligent audio squelch circuit actuated reliably, losing only a syllable or so at the beginning of some transmissions. Operating through a simplex repeater takes some practice and patience; you must stand by while your QSO partner completes a transmission and it is repeated after a four-second delay. Frequently, operators who could hear each other directly made quick-keyed exchanges without waiting for their replays. When they finished, the simplex repeater dutifully coughed up all their transmissions. But if the exchange went longer than 85 seconds, the simplex repeater keyed up immediately and began playing at the 85-second mark.

The last five seconds of the simplex repeater's memory are reserved for station identification. Five seconds was enough for me to say, "This is the KØOV hidden simplex repeater. Come and find me! But if you want me to transmit to you, you must first transmit to me on this frequency." The Micro 1.4 automatically plays the ID message after every fourth retransmission. If the frequency becomes inactive, it identifies again ten minutes after the last ID, then remains silent until another incoming signal reactivates the repeater function.

The procedure for recording the Simplex Repeater ID message is a bit tedious, but you only have to do it once. The unit must be fully functional with a transceiver attached. You will need another HT or transceiver to talk to the repeater. Press both the Record and Play buttons and wait 85 seconds for the unit to scroll to the end of memory. The LED will be on for the 85-second period, then flash to indicate it's time to record your ID message. Press and hold down the Record button while keying the HT and saying your ID message into the HT microphone, then release the Record button.

Be cautious and you'll succeed

All Agrelo DVR boards are fully assembled and tested, but using one is not a simple matter of "plug and play." Power must be +5 to +6.5 volts DC, so a regulator from your 12-volt source is a necessity. The PTT outputs will source or sink only 20 milliamperes maximum and will switch voltages no higher than the supply. This makes an external relay mandatory for keying most ham transmitters, including handie-talkies. I used an inexpensive reed relay from Radio Shack™, part number 275-232.

I mounted the Micro 1.4 on a 2-1/2" x 1-3/4" piece of unclad perforated board along with the relay and regulator circuits. Cables from this board went to the hidden transceiver's mike, speaker, and PTT connections.

You will need a good eye and a fine-point soldering iron to attach wiring to the row of 10 tiny terminals. Use utmost care in wiring up your Micro 1.4 because its ICs are susceptible to electrostatic discharge damage and the unit is not tolerant of short circuits. The manual cautions never to short the speaker terminals to each other or to ground, never ground the microphone preamp input, never exceed 6.5 VDC supply, and never press a button until all status LEDs are off. Any of these actions can cause permanent damage.

I found that the setting of the transceiver volume control is quite critical for proper Simplex Repeater operation. Not only does it determine the audio quality of the recorded and played back transmissions, it also affects the intelligent audio squelch circuit. If volume level is too high, retransmitted audio will "chop out", and if too low, it will not trigger on stations with low audio. The little LED on the board will barely flicker on audio peaks when the volume adjustment is correct. A little trial and error experimentation is in order here.

You will probably find as I did that the proper audio level setting is quite low. The Micro 1.4 intelligent squelch voltage comparator requires a DC ground reference on the audio input. If your radio's audio output is capacitor-coupled and the DC path is broken when you plug into the external speaker jack, try putting a 10-ohm resistor in parallel with the DVR audio input.

Some transceivers put out low level audio hiss or hum at the speaker jack, even when squelched. This will prevent the audio comparator from working properly. To use such a transceiver with the Simplex Repeater board, you must add a carrier-operated squelch circuit (COS) to the receiver. The Micro 1.4 has an input to accept the COS output.

Micro 1.4 DVRs are available from Agrelo Engineering, 1145 Catalyn Street, Schenectady, NY 12303, (518) 381-1057. Both the standard and Simplex Repeater models cost $69.95 each for ninety seconds total audio storage time. Twenty- and sixty-second versions are available at slightly lower cost. Custom programming is available for additional charges. For quantity pricing, warranty information, and shipping rates, see Agrelo's Web page (URL is http://home.navisoft.com/agrelo/ae.htm) or call the company. Send E-mail inquiries to JAgrelo@aol.com.

I want to hear about T-hunts you have experienced where DVRs and/or simplex repeaters were used in clever ways. I prefer E-mail for correspondence (send to Homingin@aol.com or 75236.2165@compuserve.com). I also welcome your cards and letters sent to the address at the beginning of this article.

"You won't need 50 milliwatts of audio to drive the mike input of your transmitter, but it might be useful for building decoy 'audio bunnies' to spoof the hunters as they 'sniff' on foot."

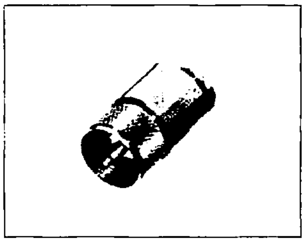
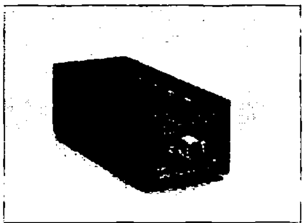
Waterproof PL-259 Available Now



RF Connectors announces the RFU-503, a UHF male solder clamp connector. This PL-259 waterproof plug features silicone rubber front and rear gaskets. The center contact is silver-plated for optimum solderability, the insulation is Teflon™, and the body is nickel-plated.

The RFU-503 is available from RF Connectors Distributors throughout the US, Canada and Mexico. For additional information, call 1-800-233-1728 or E-mail: 102061.2261@compuserve.com.



Ameco Keeps Its Cool

Ameco announces two new, high-performance broadband RF loads: Model DL 1500 is an air-cooled unit that will handle an average of 1500 watts for up to 15 seconds and 150 watts continuously from DC to 650 MHz.

Model DL 1500-F is a forced-air cooled dummy load. It will handle an average of 1500 watts for a full 30 seconds and 300 watts continuously. The DL 1500-F has a low-noise fan that helps keep the non-inductive load element cool for longer life. The SWR for both models is 1.1:1 for 160 to 2 meters, 1.5:1 to 70 cm.

Both units come in a strong, lightweight aluminum case perforated to enhance cooling. For more information, call, write or FAX Ameco Corporation, 224 East Second Street, Mineola, NY 11501. Phone (516) 741-5030; FAX (516) 741-5031.

Simple Inductance Meter

Measure small inductances with this easy-to-construct instrument.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30 - c/o Defendini
Salinas P.R 00751-0030

The ability to measure small inductances in the range below about 15 microhenries (µH) is of the utmost importance when winding toroids for VFOs, coupling transformers in receivers and transmitters. Many junk boxes contain small coils, IF transformers, and other oddments salvaged from old radios and television sets which, if one knew what their values were, might well be put to use in home-brew equipment. There are commercially available LCR meters which look like DMMs, but which cost well over $100, far more than the usual ham budget can cover. Some DMMs costing a bit less than that have an inductance measuring capability, but only in millihenries (mH) and henries, which is of little use to most hams.

What we need is a simple, inexpensive instrument which anyone can easily construct, and which will measure these important small inductances (coils) with reasonable accuracy. The simple instrument described here will enable you to measure coils in the range from below 2 µH to above 15 µH. This range includes all the values of inductance used in VFOs and most, if not all, RF coupling transformers wound on toroids.

Although this circuit is *theoretically* capable of measuring inductance below 1 µH, in the real world the unavoidable stray capacitance and inductance will usually make measurements this low impossible with such a simple circuit.

It is possible, by using a different frequency crystal than that specified, to shift the range over which measurements can be made. A lower frequency crystal, down as far as 1 MHz, will enable measurement of inductances as large as 1 mH, but the smallest value measurable will rarely be smaller than about 75 µH. Crystals between 1 and 10 MHz will allow measurement ranges between that just given and the design range of this instrument using the specified 10 MHz crystal. Use of a higher frequency crystal, up to 13 MHz, will not allow much smaller values to be measured because of the effects of stray capacity and inductance. Crystals above about 13 MHz will not oscillate in this circuit.

The circuit

Fig. 1 shows the schematic diagram of the Simple Inductance Meter. U1, a 74LS00 two-input Quad NAND Gate logic integrated circuit (chip), two resistors, a capacitor and a surplus microprocessor crystal form a stable crystal oscillator near the marked frequency of the crystal. The RF voltage is taken from pin 8 through isolation capacitor C3, to the measuring circuit. RF voltage is applied through capacitor C7 to J1, a binding post. This same RF voltage is applied to a resistive voltage divider consisting of R3 and R4. A germanium diode D1 has its anode connected to the junction between R3 and R4. RF across the variable tuning capacitor C6 is applied back through C5 to the cathode of D1 and load resistor R5, the lower end of which is bypassed to ground through C4 and applied to the positive terminal of meter M1. R6 is a *sensitivity* control connected between the negative terminal of meter M1 to ground.

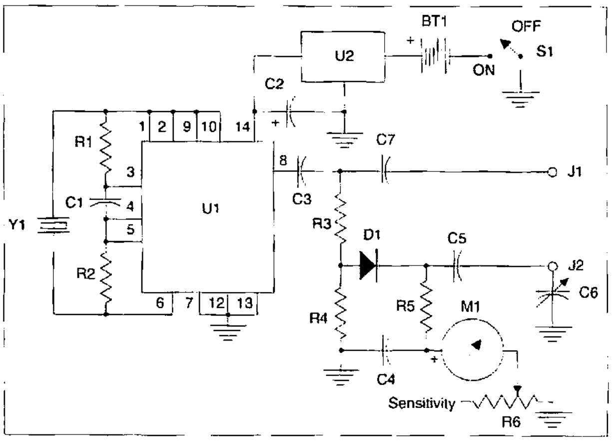

Fig. 1. Schematic diagram.

At first glance you may think this instrument uses a bridge circuit, similar to that used in my Simple Capacity Meter; this is incorrect. This instrument operates by measuring the RF voltage developed across C6, which will be the highest when the series circuit, made up of C6 and the unknown inductance, is at resonance at the crystal frequency. In other words, the value of the unknown inductance is indicated on the dial attached to C6 when the voltage indicated by M1 *peaks*, just the opposite of bridge operation.

Construction

This instrument should be constructed on a small piece of perf board or on one of the general purpose printed circuit boards available at Radio Shack™. It should be mounted in an aluminum box, or in an enclosure made from pieces of printed circuit board material, because of the high frequency at which it operates.

Capacitor C6, and binding posts J1 and J2, should be a few inches apart so that when your fingers are adjusting C6 you don't interfere with the field around the inductance being measured.

Leads between J1 and C7, and between J2 and C5 and C6, should be as short as possible, considering the physical distance between J2 and C6. This latter lead should

be bare solid wire, fairly large (up to AWG-12), and should be spaced away from the enclosure wall. Using a fairly large diameter solid wire, and spacing away from enclosure walls, will reduce the amount of stray capacity and inductance in this critical portion of the circuit. You can use as small a wire as AWG-22, but the larger the wire you use, up to AWG-12, the lower the stray inductance.

in the knob. Scribe or otherwise mark an index line on the panel extending a short distance outward from the edge of the dial.

Calibration

You will need a few small inductances of known values to use in calibrating the dial. Tiny inductances sold as RF chokes are suitable. Most are available with a ±10% tolerance, which will be adequate.

"This inductance meter should be mounted in an aluminum box, or in an enclosure made from pieces of printed circuit board material, because of the high frequency at which it operates."

Meter M1 can be either a standard 0–1 mA meter, or one of the small plastic meters originally made for CB radio or home entertainment equipment. These latter meters usually have 200–300 µA movements, and the value of R6 may have to be increased by adding a resistor in series with it if the more sensitive meters are used.

However, if you have an analog VOM with a current range of 1 mA or less, and a DC voltage range of 2 or 3 volts, you could install a pair of binding posts instead of M1 and use your VOM to read the peak voltage at resonance, saving the cost of a dedicated meter. Depending upon the Q of the unknown inductance being measured, you may need either a low current or low voltage range on the VOM.

You will have to make and calibrate a dial for C6. Most hams save the circular metal or plastic cutouts made when installing meters and small speakers. These make ideal dials when white card stock is glued to one side, trimmed, then centered and cemented or epoxied to the bottom of a knob, with the knob on the white side of the dial.

If you do not have such a circular cutout—you will probably have one if you mount a standard meter for M1—you can scribe a circle on a sheet of heavy, stiff plastic or cardboard, cut it out carefully with scissors or a hobby knife, then cut a hole in the exact center to pass the shaft of C6. If your dial does not have a clean white surface, glue a piece of white paper or index card stock on it. Trim it when the adhesive has dried, and cement or epoxy it to the bottom of the knob for C6.

Mount the completed dial assembly on the shaft of C6 and tighten the set screws

though if you use 5% tolerance chokes, such as those available from Mouser Electronics, your measurements will be more accurate.

If you purchase the following small RF chokes, using them singly and in series in various combinations will allow calibration points at approximately every microhenry from 2 or below to above 15: Buy two 1 µH; two 2.2 µH; one 4.7 µH; and one 10 µH RF chokes to use as calibration standards. Remember, if you connect inductances in series, add the individual values; if you connect them in parallel you can use the formulas for parallel resistors to determine the resulting value. Those values suggested result in only series connections, adding each value to reach the total value, *except* for calibrating at 0.5 µH, where both 1 µH RF chokes are connected in *parallel*. It is extremely unlikely that you will be able to calibrate as low as 1 µH, but you might be lucky!

Switch S1 to ON. Connect a calibration inductor between J1 and J2, adjust C6 for a *peak* indication on M1, and mark this point on the dial. Number it with the value of the calibration inductance. Continue calibrating the dial with various combinations of inductances in the same manner.

You will not be able to number each calibration point, especially if you calibrate at approximately every microhenry. The dial will be very crowded at the high inductance end, but much less so at the low end.

Operation

Switch S1 to ON. There should be some indication on M1, which shows that the instrument is functioning. Connect an unknown inductance between J1 and J2, adjust C6 for a *peak* indication on M1, using the *sensitivity* control as needed, and read the value of the unknown inductance from the dial of C6 opposite the index mark on the panel. If you are using an external analog VOM instead of M1, you may have to switch between DC current and DC voltage ranges to keep the needle on the meter scale, or you may use the *sensitivity* control.

The higher the Q (quality factor) of the unknown inductance, the higher the peak indication on M1 and the VOM. Conversely, a low Q inductance will register a lower peak indication. This simple circuit will not measure Q directly but will allow relative indications. Inductors used in frequency-determining portions of VFOs should have the highest Q possible. This means using the largest diameter wire commensurate with the space available on 70% of the toroid core used. If an air core coil is used, its diameter *and* length should be as close to the same dimension as possible, and be wound with the largest diameter wire practical. This will result in the highest Q coil possible.

Parts List

BT1	9V alkaline battery
C1,C3,C4	0.01 µF ceramic disc capacitor
C2	10 µF 16V electrolytic capacitor
C5	0.001 µF ceramic disc capacitor
C6	365 pF variable capacitor
C7	560 pF NPO, COG, Mylar™ or poly capacitor
D1	Germanium diode: 1N34, 1N60, 1N90, 1N270, etc.
J1,J2	Binding post
M1	0-1 mA DC meter (see text)
R1,R2	560 ohm 5% 1/4W resistor
R3,R4	100 ohm 5% 1/4W resistor
R5	1k ohm 5% 1/4W resistor
R6	10k ohm linear potentiometer
S1	SPST toggle or slide switch
U1	74LS00 two-input quad NAND gate

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

In last month's column. Robert Blacka N2WSO offered a good tip on a line of "camouflage" rope offered by The Lehigh Group of Allentown, PA. Since then, I've received their well-laid-out catalog of cordage and accessories, and the rope that Bob mentioned seems to be Lehigh's item # CF450 (the number mentioned in the column last month may be the dealer's stock number along with a UPC code). The catalog describes it as twisted polypropylene rope and says that it holds knots well; resists oil, gasoline and most chemicals; is resistant to rot and mildew: and floats (a trait hopefully not needed in ham radio applications). The standard length is 1/4" by 50'. It comes with an instruction booklet that outlines its proper use and care and describes knotting and splicing methods. Lehigh's phone number is 1-610-398-1830. Their catalog is worth having for general information on cordage and fittings.

Pinpoint it with a laser

We've all heard the expression "a solution looking for a problem." That's what I had considered those new "pocket laser pointers" to be until I thought about it some more. The pen-sized pocket laser pointers are advertised as being useful for large group presentations, and they no doubt are, but how many of us give large group presentations often enough to justify the purchase of one? No question, they'd be fun to play with (just don't look at it or its mirrored-reflection directly), but I needed a bit more incentive than that to spend the money for one. Well, for those of you in the same predicament, here's the justification you've been looking for, and it's a useful one.

It's usually easy to locate the correct component for replacement on the component side of a printed circuit board since the part numbers are generally silk-screened on that side, but locating the proper pads to unsolder on the foil side of the board is another matter altogether. That's where the little hand-held laser pointer comes in.

Simply hold the pointer over the correct component, on the component side of the board, and then, looking at the foil side—perhaps with the room lights dimmed a bit—you'll be able to see the exact point to unsolder. It's particularly useful with phenolic PC boards, but it even works on the heavier Fiberglas™ boards (though the light does scatter a bit more, depending on the density and "grain" of the board material).

If you'd like to drill a hole through a plastic case, but you'd also like to see where it will end up on the other side of the case before you drill, the laser light will even penetrate some of the less-dense plastics. Too bad it doesn't penetrate aluminum...or drill the hole for you...at least not yet!

Finally, our two younger cats love to chase the "red dot." Be careful not to shine the pointer directly into your own or your cat's eyes; again, intense laser light can be dangerous if misused. Lasers derive their pinpoint energy by forcing all of the photons to march in step, at exactly the same color frequency and in exactly the same direction, much like a well-drilled military marching unit. By the way, our older cat shows some (though dignified) interest, but apparently he considers the laser pen just another variation on the old "dancing-flashlight-beam game!"

These are my contributions. What problems have you solved using this latest "solution looking for a problem" device? Send me your ideas, at the address in the masthead, and I'll compile them for a future column on "sharp-laser-pointer tips."

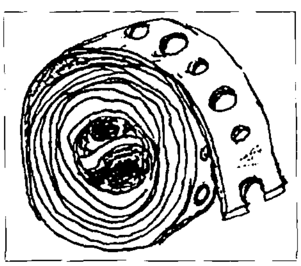

Fig. 1. Steel plumbing strap, as it comes from the blister packaging.

A strapping good idea

From James E. Brown AE4EY: This suggestion is certainly worthy of consideration. He writes: "My shack is located in the basement of my home, and the closest nearby ground is the cold water pipe running through the rafters about five feet above my operating position. In the past, I simply used wires from each piece of equipment, joined together at one connection point, then a single wire running up the wall and to the cold water pipe. The final attachment was done with a worm-geared hose clamp. There were times when I was plagued by RF feedback due to the many wires acting as resonant antennas at various operating frequencies; I also had concerns about the necessary low-resistance of a single wire grounding system.

"I spotted some steel plumbing strap in the hardware store one day, and pictured that as a much better solution to my RF grounding woes, which indeed worked out that way. The steel plumbing strap is inexpensive enough, between $1 to $2 for a 10-foot blister-packed roll. A couple of rolls of the strapping, plus a dozen 6-32 machine screws, nuts, and washers are all that you need to get going. The particular strapping I'm using is 3/4 of an inch wide and 10 feet long, containing alternating 1/4-inch and 9/64-inch holes throughout its entire length. It's made for jobs like hanging plumbing pipes from wooden rafters, and is easily cut with tin shears or a hacksaw to provide you with the exact length needed.

"**Fig. 1** shows the strapping as it comes from its blister-pack. It's easily bent around a circular fastening point or shaped any other way that might be needed to achieve the desired end. **Fig. 2** shows the connection point to the cold water pipe in my own installation and **Fig. 3** illustrates how a solid splice is made to extend the strapping length. **Fig. 4** shows how I've chosen to tap onto the main strap at each piece of equipment, and **Fig. 5** depicts how that piece of gear can be securely fastened to the tap-off using the existing grounding stud present on most amateur gear.

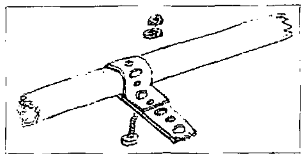

Fig. 2. The connection to an overhead cold water pipe run.

"Since installing the strap grounding system, I've experienced no further in-shack RF feedback problems. What's more, the jumble of grounding wires has disappeared and I've no further doubts about the adequacy of my shack ground system. Be sure that you ground every piece of gear, including any coaxial switches, antenna tuner and the chassis of your shack computer. The more thorough you are in this area, the fewer problems you'll experience with stray RF and/or digital noise ending up where it shouldn't be."

Jim's idea is a good one to keep in mind for your next shack rebuilding project. Since it's relatively inexpensive steel strapping, there will be some inherent RF resistance present in it, but its sheer bulk helps to minimize that factor. If you can find copper hanger strapping, so much the better, but be careful not to mix dissimilar metals if you can possibly avoid it (because of the possibility of electrolytic action taking place at the junction). Also, be sure to carefully sandpaper or wire brush all connecting points for the lowest resistance connections. Both steel and copper quickly oxidize to form high resistance surfaces. If you're using a cold water pipe as the final ground reference, make sure that

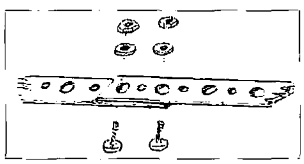

Fig. 3. Splicing two sections of strapping to extend the length.

connection is also well cleaned, and that there are no non-conductive pipes in the line all the way to where it enters the earth ground. Any water meters or other in-line devices should be bypassed with a heavy wire shunt since their carry-through conductivity may be questionable. In a basement installation, quite often a hole drilled through the concrete floor, with a 6- or 8-foot ground rod passing through it, will end up being the shortest and best path to earth ground. Be careful not to inadvertently hit any under-floor pipes or tiles!

A line of affordable project boxes

If you're anything like me, you can never have enough sources for small project boxes, perhaps for a microphone adapter, a couple of outboard switches, or maybe a small-circuit idea consisting of just three or four parts.

One such source of small boxes that I recently came across is Sescom, Inc. of Henderson, Nevada. Their mainstream business is in serving the independent television production community with cables, adapters, amplifier modules, etc., but their newest catalog also boasts a number of what they call "Mini Project Boxes" that are perfect for many ham radio construction needs. Their MPB-1 at $1.95, for instance, is only 1" x 2" x 1", and has proven to be very useful in my own ham shack for small projects. Their current full line consists of a total of 24 various-sized project boxes, from the MPB-1 mentioned to the MPB-2, measuring 1" x 4' x 1", an the MPB-3 at 1" x 6" x 1", on up to the MPB-24 at 4" x 14" x 3" at $6.10.

The boxes are an exclusive design and consist of four flat aluminum sides, two flat aluminum end pieces, four channeled-aluminum 90° "micro extruded" corner angles, and eight self-tapping steel end screws. The flat aluminum sections are .04 inch thick and are unpainted; they're easily drilled or punched medium-hardness aluminum stock, with plastic protective film on both sides for scratch protection during shipping and handling. They arrive unassembled, an interesting concept in mini-box shipping and storage that makes drilling or punching much easier since you're always working on a flat piece of stock.

Assembly takes only a few minutes, and consists of slipping the flat aluminum side plates into the channeled corner angles, then attaching the two flat end plates with the eight small self-tapping screws. The box can be primed and painted if desired—either assembled or unassembled—to match whatever piece of existing equipment the user might want to complement; or it can simply be left natural and perhaps given a brushed finish with a piece of soft steel wool.

Another interesting side benefit of the assemble-the-box-yourself design is the nearly unlimited customization of the final size. If you need a box that fits exactly into a given space, one of the Sescom "Mini-Project Boxes" may be just the answer. Simply choose the box closest in size—but slightly larger—than what you would ideally want, then cut the stock down to the exact size needed with a bandsaw, and you'll have the perfect box to fit your available space. This is something that's virtually impossible to do with pre-formed or molded project boxes.

Sescom's phone number is 1-800-634-3457, or write to 2100 Ward Drive, Henderson, NV 89015-4249, and request their latest catalog. Also unique is their free UPS ground shipping on all orders over $20—plus a 10% discount on quantities of 10 or more of the same size box. Not a bad deal.

By the way, any commercial products that I mention in this column are completely unsolicited; they're either items that I've actually tried, or ones that have been recommended by *73* readers. I've not been approached by any manufacturer and wouldn't respond if I were. The intent of this column is to inform *73* readers of ideas, tips, suggestions, and, yes, sometimes unsolicited products if they apply. It's not a paid ad sheet. I just want to make sure this is clear.

A handy paddle reversing switch

From Gary Bartlett VE1RGB: An idea that fits well into the Sescom MPB-1 project box talked about above. "As an ardent CW Op, I frequently carry my own paddles with me when operating someone else's station—such as on Field Day. Not every rig, however, is polarized the same way with regard to which input connection is 'dit' and which is 'dah.' Trying to rewire the paddles each time, in the dark or the cold, isn't really the answer. The real answer is a small, sturdy project box, containing an easily operated DPDT paddle polarity reversing switch...one that will work from one set of paddles to another, as well as from one transceiver to another. Fitted into a small aluminum box, the reversing switch (**Fig. 6**) will also allow you to change 'keying hands' quickly, such as when the need to log with your right hand forces you to send with your left. Few Ops can master that feat, but the reversing switch makes it possible."

"Quick testing" capacitors with an ohmmeter

From Peter Albright AA2AD: Some good information for us on the theory and practice of testing capacitors with the absolute minimum of test equipment. "Did you know that your analog (needle-style) multimeter can be used in the 'ohms' position to test capacitors? Although the theory is straightforward, practice is a bit tricky because of differences between real-life multimeters. Follow along and you'll see why."

THE THEORY: In a DC circuit, capacitors act like a reservoir, holding electrons rather than water. When a DC voltage is applied to a capacitor, it fills (charges) as electrons pile up on the plates. While it's charging, there is measurable current flow in the leads. Current flow, or amperage, is greatest when the capacitor just begins to charge; at the instant that voltage is first applied the capacitor looks pretty much like a short circuit, with a resistance value of near zero ohms. Current flow approaches zero as the capacitor approaches a fully charged state. When fully charged, the capacitor looks like an open circuit, with nearly infinitely high resistance. A perfect capacitor would hold this charge

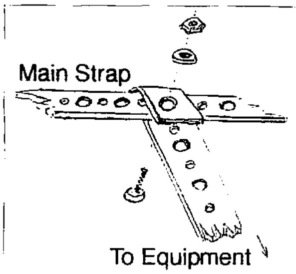

Fig. 4. Tapping into the main grounding strap for connection to an individual piece of equipment.

forever, or until the electrons are drained off by some external circuit connecting the capacitor's two plates. Even a real-life capacitor can hold its charge for quite some time.

An ohmmeter works by applying voltage across the device to be measured. Although the meter is calibrated in ohms, it is actually measuring current flow. Remember Ohm's Law:

$I = E/R$

For a given voltage, the lower the resistance, the higher the current. An interesting, counter-intuitive corollary is that analog ohmmeters put a resistor network between the meter and the device to be tested. When you switch the meter to a higher resistance measurement range, the resistance value of that network is increased.

There's one final piece to the puzzle. When a capacitor is charged through a resistor, an elementary timing circuit is created. Increasing either the value of the resistance in ohms (limiting current flow) or the value of the capacitor in farads (the size of the

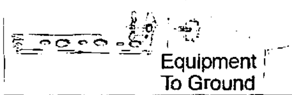

Fig. 5. Connection to the actual piece of ham gear at its rear ground stud. If a direct connection via the steel strapping isn't practical (because of the need to pull a particular piece of equipment out to gain access to the rear apron), then a short piece of flexible braid with a terminal lug installed on it (such as the braid from the inside of an RG-8 coax cable) can be used as a jumper to the main strap.

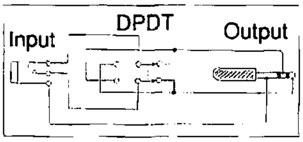

Fig. 6. VE1RGB's CW paddle reversing switch used to flip-flop the "dit" and "dah" connections on oppositely wired amateur transceivers, or for changing "fists" under contest conditions.

"reservoir") will increase the amount of time that it takes for the capacitor to charge fully, and for that charging current, measured in amps, to drop to zero.

THE PRACTICE: As always, begin with a careful visual inspection. Defective capacitors are often physically deformed by bulging, leaking, or showing heat damage. They may be "microphonic," showing functional instability when tapped gently with a plastic stick while the circuit is active. A microphonic capacitor is bad, and no further testing is indicated. After you have decided that there might be a defective capacitor in the circuit, follow these steps:

1. Turn the rig off and unplug it, or remove the battery if that's the source of power.

2. This step is important—it protects you, your equipment, your tools and even the component to be tested. Make sure that the capacitor is fully discharged by placing a direct short between its two leads or terminals with a clip lead. Remember to be careful: If the capacitor is a large value power supply electrolytic cap, it can deliver enough current to put a nice nick in your screwdriver blade, even at 12 volts! It's always a good idea to discharge large capacitors (or capacitors in high-voltage circuits) through a 100 ohm, 2 watt resistor for a full minute or more before putting a dead short across its leads.

3. The capacitor to be tested must normally be removed from the circuit. It's sufficient to disconnect only one lead, leaving the other lead soldered in place since it's only a two-terminal device. After you disconnect the capacitor, discharge it again to be sure its "reservoir" is completely "empty." Even with a dead short across it, a capacitor may take several seconds to discharge completely, because of its inherent internal resistance. Good technicians always practice accepted safety techniques!

4. Now set your analog multimeter to measure resistance. The range setting that you'll choose will depend somewhat on both the value of the capacitor to be tested and the characteristics of your particular meter. On my favorite meter, I generally use the R times 1 range for electrolytic capacitors larger than 50 µF, and the higher scales for those smaller capacitors—up to the maximum of the meter's range for very small ones of .001 µF or less. Remember the theory above? By changing the meter's range setting, you're putting different resistances in series with the capacitor, thus making the time constant of this series charging circuit long enough so you'll be able to see the meter move as the capacitor takes on a charge.

5. Next, connect one ohmmeter lead to one of the capacitor's leads. For electrolytic capacitors, be sure to observe polarity of the capacitor as marked on the case. You can't assume that the negative lead of your ohmmeter applies negative voltage to the outside world, so check your ohmmeter's polarity with a second voltmeter.

6. Watch your meter's needle and touch the free meter probe to the other capacitor lead. The needle should quickly swing toward zero ohms, then reverse direction, and then more slowly work its way back toward infinity. The speed at which this happens depends on the value of the capacitor and the characteristics and range setting of the multimeter. If all of this happens too fast to see, return to Step 3 (discharge the capacitor) and try a higher range setting on your multimeter. If, on the other hand, the meter's needle moves excruciatingly slowly, you can simply switch the meter to a lower range setting without harming anything.

7. If the meter never swings toward zero ohms, the capacitor is open, and defective. If the meter never returns to infinite resistance, the capacitor is "leaky."

8. When the meter reaches infinite resistance, remove one lead. Wait about 20 seconds, then reconnect the lead. The meter may twitch a bit, but if it noticeably swings back toward a low resistance reading, the capacitor is leaky. A good capacitor holds a reasonable charge for longer than 20 seconds.

"You can practice this technique on a variety of capacitor values to get a feel for what should happen with the different sizes, and to determine which range on your own multimeter gives you the most satisfactory reading times. You should get no false negatives: If the capacitor is leaky or open, it's bad. A good reading is not absolutely conclusive, however, because the capacitor may break down under the higher voltage of the actual circuit it's being used in, or it may have changed in value. This 'quick test' tells you nothing about the capacitor's voltage breakdown point, nor does it give more than a rough idea of the actual value—other than by the time it takes to charge through a certain series resistance.

"Also, keep in mind that when replacing a capacitor in any tuned circuit, it is important to use an exact replacement, both in terms of value and type (the material that the capacitor is made of can be critical). The higher the frequency at which the circuit operates, the more critical that replacement exactness becomes. The replacement capacitor's lead lengths should also match the original and its physical placement should replicate the original as closely as possible.

"In the case of power supplies you have some more leeway. Except for the voltage rating, which should be the same or slightly higher, the capacitor's value can generally be up to 150% higher than the original.

"Finally, never use a capacitor with a lower voltage rating than the original, and always strictly observe the polarity markings on electrolytics and tantalums. If you ignore this caution, you'll eventually have a capacitor explode inside your rig like a small firecracker, leaving you with an unpleasant cleanup job."

Hot tips!

From Michael Fratus: A tip on how to spot broken solder connections in ham radio equipment. "Solder breaks make up a higher percentage of direct and indirect causes of failure in electronic equipment than many people think. When working on any ailing printed circuit board, if you notice a semicircular ring around a solder joint—or any sign whatsoever of crystallization or fatigue—touch up the connection with an appropriately hot soldering iron and a bit of fresh 60-40 solder. Pay special attention to the connections on heavier components, any PC board connectors, and all board-mounted controls for signs of 'flex' stressing. This can be a problem, particularly in a mobile environment where lots of vibration is present, and in areas of extreme temperatures.

"Any 'stress fractured' solder joint can become thermally unstable, resulting in an intermittent connection with hot and cold, and is often responsible for what might seem bizarre symptoms. Unless you solve the real problem, you'll be working on that piece again! Taking the time to quality-check the unit while you have the board exposed will give you more time for operating and less for servicing in the future!"

Did someone say "Underground"?

From Bill Thim N1QVQ: An idea for running "coax underground back to your shack using PVC piping as a raceway. It helps protect the coax and also makes running any other cables in the future an easy job. You can buy PVC pipe with holes already drilled into one plane of it, in 4"

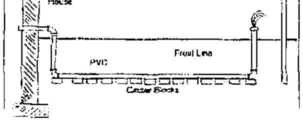

Fig. 7. Side view of the overall PVC pipe/cable raceway scheme described in the text.

and greater diameters. Four inches may sound like a lot, but it can fill up fast if your station antenna farm begins to grow...whose doesn't? The bigger you can manage, the better. Of course, you can also drill holes along a length of smaller PVC pipe if your future plans are more modest. The proper way to lay the pipe underground is shown in **Fig. 7** and **Fig. 8**. Dig a moderately sized trench, preferably below the frost line. When the pipe is laid, the holes should be straight down, the pipe should rest on blocks or loose gravel for drainage (cinder blocks with the hollow channels pointing up and down are an excellent choice). The entire length of pipe should then be 'draped' with plastic sheeting over the top, to act as a water-diverting shield when the soil is placed back over the top of the trench. Sounds like a good bit of work—and I suppose it is—but doing it correctly will save you countless problems in the future.

"A way to handle the out-of-doors end of the run is to construct a 'weather elbow' out of PVC fittings as shown in **Fig. 9**. This type of scheme will not allow water to enter the pipe's end, yet will provide easy access for new cable runs in the future, though more 90° turns are involved. A wad of Fiberglas™ insulation pushed into the end of the pipe will discourage insects and other unwelcome visitors!

"Ideally, the shack end of the pipe should go through the wall of the building itself, for maximum convenience and weather-resistance. You might even put a small 'hamfest-gem' 3- or 4-inch whisper fan at the building end, pulling air from the pipe into your shack, for free cooling in the summer and warming in the winter! The fan will also help to replace the air inside the pipe and keep it dry.

"Finally, an electrician's 'fish tape' should be used for the initial cable pull...don't forget to put in some sort of 'come-along' rope that can be used for future pulls. It can be a loose rope running along side of the cables, or a 'trolley' arrangement, configured with a loop of rope, separately hung, running the entire length of the piping. Sometimes, a loose come-along rope, though simple to install, will wind around the cabling, making it more frustrating to pull in future runs. Consider using the trolley idea if you can; **Fig. 10** shows one way that this can be accomplished on a fairly straight run. Its practicality depends, to some degree, on the length of the run and on the size (diameter) of the pipe. Choose whichever method you feel is most practical for your own installation."

It's obvious that Bill has thought out the problem well, and his suggestions might apply to all of us, no matter what antenna system we might have in mind. As Bill pointed out, it's vitally important to keep an underground conduit raceway dry. Coax cable was never meant to "tread water." Make sure that the cable you choose for an underground setting is free of any (even slight) defects in the outer jacketing. Any moisture whatsoever inside the shielding of the cable will literally destroy the RF shielding quality and conductivity of the cable's shield conductor. The braided shield must make good electrical contact with its neighboring wires to represent a continuous "pipe." We can get away with the flexibility of a braided shield in our cables—as opposed to a solid outer piping—only because each strand of the shield overlays every other strand, simulating a continuously-walled pipe; but that simulation must be maintained throughout the length of the run. Be sure to tune in next month for more worthwhile tips, ideas and suggestions.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

A field of their own

Field Day is once again just around the corner—June 22nd and 23rd. Every year the American Radio Relay League sponsors the event as an exercise in emergency preparedness. Amateur radio groups in the United States and Canada take their ham gear, generators, batteries, and antennas outdoors for the competition. The object is to work as many stations as possible on the amateur bands from 1800 UTC Saturday for 24 or 27 hours (depending on when station setup began).

By the ARRL rules, completing one satellite contact during Field Day earns a 100-point bonus. Contacts via satellite beyond that are lumped together as one "band" and get the same points as other Field Day contacts. Twenty years ago these rules were adequate for the satellites of that time, but today, with a dozen hamsats in orbit, the situation has changed. In an effort to inspire more groups to set up and operate serious satellite stations during the weekend, AMSAT, the Radio Amateur Satellite Corporation, sponsors its own version of Field Day. The dates and times are the same, but there the similarity fades.

The AMSAT competition is to encourage the use of all amateur satellites, both analog and digital. The AMSAT competition is open to all satellite enthusiasts, both domestic and foreign. American and Canadian stations should exchange ARRL section and transmitter-class information. Foreign stations should exchange signal reports and country names. This year CW contacts and digital contacts are worth three points each as outlined below.

1996 AMSAT FIELD DAY COMPETITION RULES:

Analog Transponders

- Each satellite transponder is considered a separate band. This means that AMSAT-OSCAR-13 Mode "S" is separate from A-O-13 Mode "B."
- All phone QSOs and all CW QSOs on a given satellite transponder are considered separate bands. This means that A-O-13 Mode "S" CW is separate from A-O-13 Mode "S" phone.
- Therefore, for reporting purposes, A-O-13 has four possible "bands" including Mode "B" CW, Mode "B" phone, mode "S" CW, and Mode "S" phone.
- All packet/RTTY/ASCII/AMTOR QSOs through analog transponders are counted as CW QSOs.
- Phone QSOs count for one point and CW QSOs count for three points.
- Cross-mode (CW–phone) contacts are not allowed.
- The use of more than one transmitter at the same time on a single satellite transponder is prohibited. This means that two stations at the same Field Day site can operate through A-O-13 at the same time, but only if one is operating Mode "S" and the other Mode "B". If two stations at a given site are set up for Mode "B" operation, only one can be on A-O-13 (CW or phone). The other station can be used for different hamsats (like A-O-10) or other Field Day activities.

Digital Transponders

- For the pacsats (L-O-19, K-O-23, etc.), each satellite is considered a separate band.
- Do not post "CQ" messages. Simply upload ONE greeting message to each satellite and download as many greeting messages as possible from each satellite. The "subject" of the uploaded file should be posted as "Field Day Greetings" addressed to "ALL." The purpose of this portion of the competition is to demonstrate digital satellite communications to other Field Day participants and observers.
- The following uploads/downloads each count as a three point digital contact:

(a) Upload of a Satellite Field Day Greetings file (one per satellite).

(b) Download of Satellite Field Day Greetings files posted by other stations. Other non-Field Day files are not to be counted for the event.

- Satellite digipeat QSOs do not count for any score and the use of gateway stations to uplink/downlink is not allowed.
- The *Mir* PBBS is not to be used for Field Day operations.
- If F-O-20 is active, the JA transponder can be used for analog CW and phone activities under the analog transponder rules, and the JD system can be used as a separate transponder under the digital rules.

Sample Satellite Field Day Greetings File

"Greetings from N5EM Field Day Satellite station near Galveston, Texas, with 24 participating members in the AMSAT-Houston group. All the best and 73!"

Note that the message stated the call and name of the group, where they were located and how many were in attendance.

Operating class and reports

Stations operating portable and using emergency power (as per ARRL Field Day rules) are in a separate operating class from those at home connected to commercial power.

A Satellite Summary Sheet should be used for submittal of the AMSAT Field Day competition results. A copy of this form will be in the AMSAT Journal or can be obtained from me at the address above for a self-addressed-stamped envelope. Deadline for submissions is August 1, 1996.

Competition was tough in 1995 and should be even tougher in 1996. The station submitting the highest score for portable operation using emergency power will receive a plaque at the AMSAT General Meeting and Space Symposium in Tucson, Arizona, November 8-10. AMSAT hopes this event provides satellite operators with the practice necessary to set up a ground station and effectively operate via the satellites in an emergency situation. Remember that Field Day also provides a good opportunity to expose newcomers to the amateur radio satellites. Most of all, it should be a great time! 73

More on K1BQT's 15m rig

Last month, we got the transmitter up and running on the 15 meter CW transceiver described by Rick Littlefield K1BQT (*Ham Radio*, January 1989). This month, we'll take a look at the receiving half of the transceiver.

The receiver

Since the receiver is a bit more complex than the transmitter, I've added a block diagram (**Fig. 1**) to guide you though the signal flow. As I mentioned before, I can't reproduce the circuit here.

Basically, the input to the mixer is simple and to the point. A NE602 mixes the incoming signals with the VFO's output. As we saw in last month's column, the front-end mixer also produces the required VFO energy.

Unlike some of the more recent club rigs, like those of the NorCal and NW QRP clubs, the 15 meter rig has four crystal filters. In fact, by matching the crystals, a very tight IF filter is possible. However, I like my CW a bit on the wide side, so no attempt was made to fine-tune this filter. In fact, common computer clock oscillator crystals are used. Digi-Key and Mouser Electronics carry a wide selection. Surplus electronics houses have computer clock crystals in stock as well. Most of the crystals may be had for less than a buck apiece. Pick up a handful; you'll need more than four if you plan on matching them.

After the incoming signal has been mixed and passed through the IF filter, the signal is then applied to an MC1350 IF amplifier. My dealings with this guy have been less than happy!

The MC1350 will easily go into oscillation at the drop of a hat. A common fault most builders have when working with this chip is using an IC socket. The extra lead length combined with the high gain of the amplifier produce all kinds of unusual critters. If you have trouble with an MC1350 and have it installed in an IC socket, remove the socket and solder the 1350 directly to the PC board.

"Most of the crystals may be had for less than a buck apiece. Pick up a handful."

When laying out a PC board, make all the copper traces to and from the 1350 as large as possible. This will keep unwanted inductance out of the circuit. Use a top ground plane if possible; again, keeping inductance down to a minimum.

On this rig, the output of the 1350 is applied directly into an NE602. Here the IF frequency is mixed with the BFO crystal. In my block diagram (**Fig. 1**), I did not show the trimmer capacitor used to net the BFO crystal. Nor did I show the capacitor used to couple the output of the 1350 into the NE602.

Audio

Rick uses a standard audio filter comprised of two op amps. A single 1458 amplifier is used. Rick allows you to select or bypass the filter by a double-throw double-pole switch.

From the audio filter, or directly from the BFO mixer, the audio is fed into an LM386. This 500 mW audio amplifier has become the standard in most QRP rigs. However, in Rick's design, the gain is set high and the volume to the speaker is through an "L" pad arrangement. This is very similar to the design Rick used in the MFJ rigs he designed.

A simple audio-derived AGC controls the gain of the receiver by constantly adjusting the gain of the IF amplifier.

Making the rig work

As with so many projects in various magazines, there are some mistakes in the instructions. Perhaps the most lethal is the lack of interconnections between the relay used for T/R switching and the rest of the circuits.

In the original article there is no mention of how or why the wires should run from the relay contacts to the other parts of the circuits. This one caught even me by the short hairs. Only after spending several hours wondering why the PA was drawing an amp of current without output did it occur to me to trace the output back to the relay. The fix is simple: Use hook-up wire to complete the wiring.

My buddy used computer clock crystals for the IF filter. That's exactly what I said to do. However, in his case the crystals he used were for oscillators used in wristwatches! They just plain did not work in the circuit. The fix? Replace all the crystals used in the filter.

Super-small QRP rigs are a trademark of Rick Littlefield, but most builders don't have access to the vast array of micro parts Rick does. So, to fit some of the silver mica capacitors on the PC board, they must be installed on the foil side. This means that the PC board has to be installed a bit higher off of the metal cabinet, which also means that the leads on the PA transistor have to be a bit longer than necessary.

Another sticky point is that the AGC components are not on the PC board. They are located "sky-wiring style" on the front panel. Without the AGC parts, the gain control to the 1350 is left to dangle. That makes for a rather interesting way to control the gain of a pesky amplifier like the 1350. I got around the problem by supplying the 1350 with enough gain to test out and align the stages. The AGC components will be installed when the circuit board goes into its case.

Building your own version

You might be able to get a PC board for the rig. The original article stated that PC boards were available from RadioKit; I don't know if RadioKit is still around. You might try Far Circuits (18N 640 Field Court, Dundee, IL 60118). Perhaps they have the boards, or the artwork to produce them.

That's all for the QRP 15 meter rig. All we need now is a zillion or so sunspots so we talk to someone else on 15 meters!

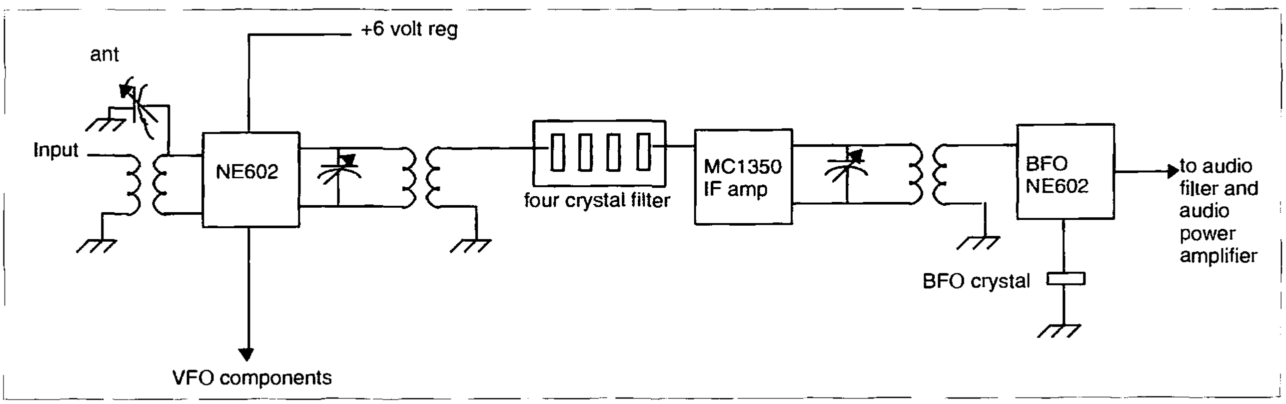

Fig. 1. Block diagram of the 15 meter CW transceiver.

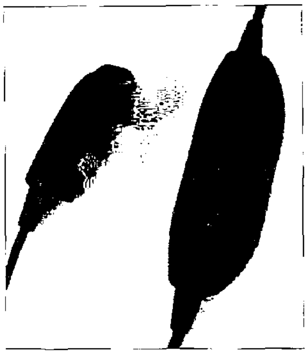
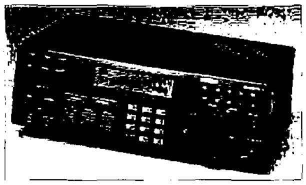
MORE NEW PRODUCTS

An Ear Microphone?



Genesys Products Group's Eartalk Mark II combines an earphone and a microphone in their ear unit, picking up your voice via your inner ear. It has a separate PTT switch (with a lock). It's designed for nearly hands-free use with mobile rigs and HTs—no more mike boom out in front of your face. There are models for Icom, Kenwood, and Motorola. The price? $84.95. Geyesys, 10815 Gulfdale, San Antonio TX 78216. Phone (800) 847-4745 or FAX (210) 349-4300. E-mail: genesys@connecti.com.



Proud Addition to MCM's Catalog

Scanning Radios from Uniden America, known worldwide as the leading manufacturer of handheld, mobile, and tabletop scanners, are now being distributed by MCM Electronics.

MCM's semiannual catalogs are also widely known, and MCM's distribution centers enable ground-rate shipping to most of the U.S. within 48 hours. 99% of all orders are shipped within 24 hours. For more information and a free catalog, call 1-800-543-4330.

New Lattice Programmable Logic Development Kit for PC

APS announces the release of its APS-L1016 programmable logic development kit. The system consists of the Lattice pDS(r) Design Software and a test board with a Lattice ispl016 in-circuit programmable logic chip and an ispGDS22 programmable switch matrix. The kit allows for the partitioning, place and route, simulation and hardware implementation, all from the PC keyboard, without burning PROMS or changing parts. The kit sells for $250 and is ideal for evaluation and testing of programmable logic.

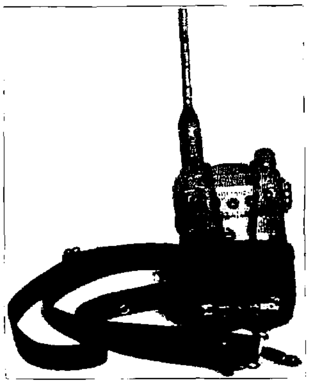
Contact APS (Associated Professional Systems) by phone (410) 515-3883 or FAX (410) 661-2760, or write to: 3003 Latrobe Court, Abingdon, MD 21009.

Vehicle Security Systems

A L Brown, Newnes Publishing, 1996, 86pp., $29. The subtitle is: "Build Your Own Alarm & Protection Systems." If you enjoy building small projects, you're going to love this book. It even has the board layouts for you. It covers car and garage and home alarms, delay circuits, ultrasonic, infra-red, and so on.

The security business is still an easy and profitable business to start in your spare time, and experience that independent feeling that having your own business brings. You may win big or you may fail, but no one can downsize you to the unemployment office, or move your job to Mexico...Wayne

Strap That Baby On!



The new "CLC503" padded Cordura nylon carrying case from Standard is made for both the C508A and the C108A mini-handhelds by Standard. It has nylon cord retainers to secure the radio in place, and a loose-weave nylon adjustable shoulder strap, to keep it comfortable slung over a shoulder or around the neck. The CLC503 attaches to a belt, or even stands up on a desk.

Suggested list price is $19.95. See your amateur equipment dealer or contact Standard Amateur Radio Products, Inc. at P.O. Box 48480, Niles, IL 60714. Phone (312) 763-1181; FAX (312) 763-3377; or reach them on the Web at HTTP://WWW.STDRADIO.COM.

New Version of AEA MacRatt – MacRatt™ III

Advanced Electronic Applications, Inc., is now shipping the new AEA TNC control program. It has totally re-engineered the new MacRatt III to take advantage of the powerful features of the newer Macintosh operating systems.

This new software provides users with a simple, multifunctional terminal control program for the AEA TNC. On packet, each station you connect to will have its own adjustable split-screen window. Stream switching is automatic; just click your mouse on the window. A monitor/unproto window will display incoming packets. Unproto packets (to send CQ, for example) may even be sent while connected to others. For those TNCs with PACTOR, AMTOR, RTTY (Baudot & ASCII), Morse, etc., there are convenient interfaces built in to make these modes even more enjoyable to operate. Frequently used commands may be selected for the menus, dialog boxes, and buttons on the windows.

Suggested list price for MacRatt III is $99. Check with your amateur radio equipment dealer for the best price; upgrades for people who currently own MacRatt I or II are available only from AEA for $55.50. For details, call the 24-hour AEA Literature Line at (206) 712-8054; FAX them at (206) 775-2340; mailing address is AEA, P.O. Box C2160, Lynnwood, WA 98036.

New Stinger For Yellowjacket

Cubex proudly announces the Stinger, a new add-on supplement to its popular 2 meter "Yellowjacket" four-element quad antenna. The three-element Stinger is simply added to the director end of an existing Yellowjacket antenna, thus providing a solid seven-element quad antenna with 50% more gain than the Yellowjacket alone, without any special tools or tuning. The Stinger comes with a Fiberglas™ boom coupler and an aluminum boom/mast coupler plate.

The Stinger is $44.95 plus $7 shipping and handling; or $85.50 as a package with the Yellowjacket, plus $9 shipping and handling. It's available from the Cubex Quad Antenna Company, 2761 Saturn St. "E," Brea CA 92621. Phone (714) 577-9009 or FAX (714) 577-9124.

Ham Radio Fun

Communications Simplified, Part 6

by Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Now that we've looked at wires and fiber optic cables for communicating, let's look at wireless communications—radio.

Is radio just high power?

Beginning students of communications sometimes think that transmitting a radio signal requires nothing but a lot of power. Are they right? Let's see.

Suppose you try the experiment shown in **Fig. 1.** Here we have a transmitter, which consists of a microphone feeding a high power audio amplifier (such as a hi-fi amplifier), and the output of the amplifier going to an antenna. The receiver is just another antenna, feeding a high gain audio amplifier (such as a hi-fi preamp) which takes the tiny signal received by the antenna, and amplifies it enough to feed a speaker. Would this work?

Some of our more advanced readers may laugh at the idea, but before they jump in, let me give you the answer: "YES! If you do it right."

The catch is that you need a big enough antenna. As a general rule of thumb, an efficient radio transmitting antenna has to be about a quarter of a wavelength long. You can make some compromises and make it smaller, but (except for some special loop antenna designs) this reduces its efficiency tremendously.

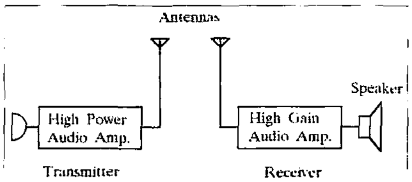

Fig. 1. Would this work for radio?

To transmit audio, let's assume we want to cover the frequency range from 20 to 20,000 Hz. Using the formula for the wavelength at 20 Hz, and using the speed of light in our equation, we get

λ = velocity/frequency = 186,000 miles per second/20 Hz = 9300 miles

An antenna one quarter wavelength long would then have to be 9300/4 = 2325 miles long!

Would it work? Sure, but would it be practical? Of course not! So how are we going to transmit a voice or music by radio?

To make radio practical, we have to shorten the antenna to some more reasonable length, and that requires that we shorten the wavelength. Looking at the above equation, we see that there are only two ways to do that: either reduce the speed of light (hmm...there's an idea there), or increase the frequency.

I suppose we could all learn to talk like the Chipmunks™ but this would not be enough. To reduce the antenna length a lot, we must increase the frequency *a lot*.

The solution to this problem is not to send the voice or music by itself at all, but to send a much higher frequency signal called the *carrier*, and to let the voice, music, picture, or whatever, ride on top of that carrier.

For example, if you look at the dial of an ordinary AM radio, you will see numbers ranging from 540 up to 1600. These numbers represent the frequencies of the carriers for the AM broadcast stations, which (for this type of radio) range from 540 kHz up to 1600 kHz.

One of the radio stations close to our school is WCBS in New York. It is about six miles from our campus, and we can pick up a very strong signal from them. Their carrier frequency is 880 kHz; let's see how long an antenna they need at this frequency:

λ = 186,000 miles per second/880 kHz = 0.21 mile

which is about 1,116 feet. A quarter-wavelength antenna would therefore have to be 1116/4 or about 279 feet long. WCBS's antenna is actually a vertical tower, somewhat over 250 feet tall. Rather than have an antenna mounted *on* the tower, the tower itself *is* the antenna. It is mounted on insulators, so it acts as a giant pole, pointing up to the sky.

Modulation

The process of putting our signal on a carrier is called *modulation*. In the transmitter, it is done by a *modulator*, and in the receiver our desired signal is removed from the carrier by a *demodulator*, also called a *detector*.

The carrier itself is a high frequency sine wave. Although the carriers for the standard AM broadcast stations are in the range of 540 to 1600 kHz, carrier frequencies can be much lower as well as much higher. The US Navy operates some transmitters with carrier frequencies about 10 kHz; on the other hand, microwave transmitters often have carriers above 10 GHz—that is more than 10,000,000,000 Hz.

Modulating a carrier involves changing it in step with the signal (voice, music, picture, or whatever, but we will talk only about audio for now) that we want to send. Since the carrier sine wave has a frequency, an amplitude, and a phase, any of these three can be changed with

modulation. When we change the amplitude, we produce *amplitude modulation* or AM, changing the frequency produces *frequency modulation* or FM, and changing the phase produces *phase modulation* or PM. We will begin by looking at AM, and leave FM and PM for later.

Amplitude Modulation (AM)

All of the radio stations on the standard AM broadcast band use amplitude modulation, a method which dates back to the very beginnings of radio.

Fig. 2 shows a sample of amplitude modulation. At the top, we see a typical audio signal. Underneath it is the *unmodulated carrier*, a plain sine wave with a much higher frequency than the audio signal; at the bottom is the carrier with the audio modulated onto it. Note how the modulated carrier (bottom waveform) becomes bigger when the audio is positive, and becomes smaller when the audio is negative. If the audio wave is near zero volts (right in the center of the audio wave), then the modulated carrier is the same height as the unmodulated carrier.

If you take a pencil and carefully connect the tops of each cycle in the modulated carrier, you get a curve that looks just like the audio signal. This is the dark curve in **Fig. 3**, and it is called the "envelope."

The modulator in the transmitter takes the audio and uses it to vary the amplitude of the carrier; the demodulator (detector) in the receiver then uses the envelope of the carrier to recover the audio, and throws the carrier away.

A simple AM receiver

Fig. 4 shows the diagram of a very simple AM receiver, called a *crystal radio*, that can be built at home with just a few parts. The unique thing about it is that it needs no battery or power supply, and so provides absolutely free radio reception, but since "there is no such thing

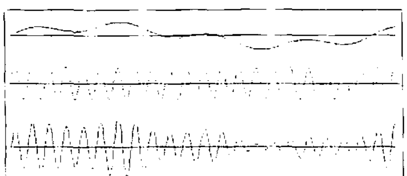

Fig. 2. Audio, carrier, and AM modulated wave.

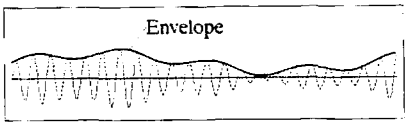

Fig. 3. The envelope.

as free lunch," there has to be a catch. The catch is that the radio really does need some power, and that power has to come from the radio station. This radio will only work if you are close enough to a radio station to receive a strong signal.

The antenna, a long length of wire preferably strung somewhere outside the house (but away from electric power wires), picks up many different signals, including AM and FM radio stations, TV stations, taxi and police radios, and more. The first thing to do is to remove the stations we don't want, and keep only the one we do want. This is done by a tuned circuit consisting of the antenna coil and the 365 µF variable capacitor; the antenna coil acts as both a transformer and an inductor in the tuned circuit.

Years ago, these two components were very easy to get in almost every radio store; today they are hard to find. Suitable replacements can be made from more modern parts, but it is probably easier to buy a commercial crystal radio kit, such as the one from Radio Shack™ (which uses a slightly different circuit, but it works the same way). When the right coil and capacitor combination is used, turning the capacitor from one end to the other will tune the radio through the 540 kHz to 1600 kHz range of the AM broadcast band.

Ideally, the output from the tuned circuit should contain only the modulated carrier from the one station we are tuned to; alas, that's not the way it usually works out. A single tuned circuit is usually not good enough to keep one station and remove all the others; a normal radio needs several tuned circuits working together to accomplish that. What usually happens in the crystal radio is that we have the one desired station, plus the signals from a few adjacent stations. If the station we want is strong and the others are weak, then the radio will work well, but if the desired station is weak and the others are strong, then we might as well give up—we will not be able to hear the station we want.

The modulated carrier is now sent to the diode. Since a diode conducts in only one direction, only half of the signal gets through it. In this case, only the positive peaks of the carrier make it through the diode. When these peaks hit the 0.001 µF capacitor, they charge it up (if you're familiar with power supplies, then you can think of the diode as the rectifier, and the capacitor as the filter which charges up to a DC value and removes the ripple). The capacitor basically charges to the voltage of the envelope. The voltage of the envelope keeps changing in step with the audio, and so the capacitor voltage also keeps changing. This voltage is then sent to the headphones.

Although the crystal radio circuit looks simple, actually all the components have to be just right, or it will not work properly. For example, the antenna coil and capacitor must be the right values to tune to the band; the ratio of turns also has to be right to give the maximum signal. For best reception, the diode should be a germanium diode, not a silicon one which needs more voltage to operate. The capacitor value is also somewhat important—it has to be large enough so it removes the carrier, but small enough so that it doesn't remove the audio signal (Actually, the radio will even work without this capacitor, but not quite as well). Even the headphones must be chosen carefully. They must have a high resistance (1000 ohms or more) to prevent shorting the signal; that means that the kind of headphone usually supplied with the "walk-person" type tape players will not work. In their crystal radio kit, Radio Shack omits the 0.001 µF capacitor, and uses a crystal headphone which has a very high resistance.

This kind of radio is called a crystal set because of the diode. Some 60 years ago, when crystal radios were very popular, tiny germanium or silicon diodes were not even invented yet. Instead, the crystal set used a small piece of galena crystal and a "cat's whisker."

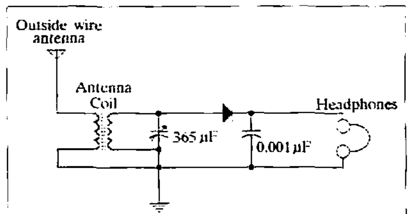

Fig. 4. A crystal radio receiver.

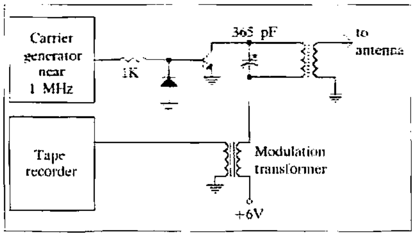

Fig. 5. A simple AM transmitter lab experiment.

The cat's whisker was a thin, springy wire which pressed against the galena to form a diode junction, and then was attached to a small handle with a knob. You had to probe the crystal to find a "hot spot." Tuning and adjusting such a radio was almost an art (and a lot of fun!)

A simple AM transmitter

Now that we see how the AM receiver works, let's see how the transmitter works. **Fig. 5** shows a simple circuit that our students wire in lab.

Rather than wire up our own oscillator, we use a commercial signal generator to generate a carrier. Our students first use a portable radio to find a clear spot on the dial, and then tune the generator to that open frequency, which is usually near 1 MHz.

The signal generator is fed to the base of the transistor. Since the transistor has no base bias, it only conducts when the generator's output is sufficiently positive (above about 0.7 volts) to bias it on. Thus, the transistor conducts only some of the time. But when it does conduct, there is enough voltage and current in the base to turn it on all the way.

The transistor, therefore, behaves like a switch, which is turned on and off roughly 1,000,000 times per second. This applies a square wave on-off current to the tuned circuit at the carrier frequency. As we have seen in previous installments, a square wave consists of a fundamental frequency plus harmonics. But the tuned circuit gets rid of the harmonics, so the signal going out to the antenna should (hopefully!) be just a sine wave at the carrier frequency.

The size (amplitude) of that sine wave depends on how much voltage gets switched by the transistor. Although the collector voltage supply is shown as +6 volts, the modulation transformer in series with the DC input changes that. When we play a tape on the recorder, the audio signal sent to the modulation transformer is alternately positive and negative, varying in step with the audio. The secondary voltage on the transformer is therefore also alternately positive and negative. When it's positive, it adds to the +6 volts to produce more voltage (and a bigger output carrier signal), and when it's negative, it subtracts from the +6 volts to produce less voltage (and therefore a smaller output carrier). In other words, the audio signal from the modulation transformer amplitude modulates the carrier.

Modulation percentage

There is a limit to how big that audio signal can get because when the transformer output reaches -5.9999 volts (or approximately -6 volts), it subtracts from the +6 volts to give almost zero; at this point, the signal becomes so tiny that it almost disappears. If the transformer output were to get even more negative (such as -7 or -8 volts), the collector would go negative, and the carrier would be shut off completely for a while.

The point where the signal just barely disappears is called 100% modulation, and is the maximum that we can vary the amplitude. At this point, the transformer output would have a maximum (peak) amplitude of ± 6 volts, so that the collector voltage would vary from its normal +6 volts all the way down to 0 volts, and up to a maximum of +12 volts.

100% modulation is a technical limit on how much you can modulate, but it is also a legal limit. If you tried to modulate more than 100%, your carrier would alternately go on and off; this would create a lot of interference to other stations, and the FCC would go after you for improper operation of your transmitter.

Fig. 6 shows a carrier with three different amounts of modulation: 0% (which is no modulation at all), 100% (which is the maximum permitted), and 50% (which is halfway between).

Actually, 100% modulation is just barely permitted, since it does cut off the carrier for an instant. Most AM transmitters are set up so they will use a maximum of perhaps 95% or 98% modulation, just to avoid the possibility of accidentally going over 100%.

Let's take a closer look at **Fig. 7**, which shows some unknown percentage of modulation. How can we figure out the actual percentage? It's actually quite simple. First, note that the maximum carrier voltage (called V_{max}) is 21.1 volts, while the minimum carrier voltage (called V_{min}) is 3.7 volts. Assuming symmetric modulation (meaning that the audio signal goes up the same amount as it goes down), this would place the average carrier voltage without modulation (shown as V_c at the left) halfway between the maximum and minimum. This is the average voltage, found from:

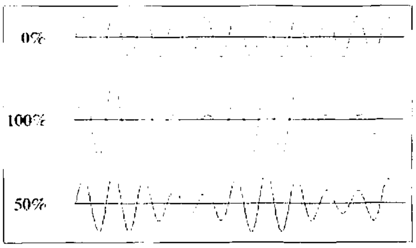

Fig. 6. Three different modulation percentages.

$$V_C = V_{max} + V_{min}/2 = 21.1 + 3.7/2 = 24.8/2 = 12.4 \text{ volts}$$

At the peak of the modulation, the voltage goes from 12.4 up to 21.1, which is an increase of (21.1 - 12.4) or 8.7 volts. At the valleys, the voltage goes from 12.4 down to 3.7, also a decrease of (12.4 - 3.7) or 8.7 volts.

To find the modulation percentage, we have to ask this question: A drop of 8.7 volts is how many percent of the maximum possible drop? The maximum possible drop (which is 100% modulation) is 12.4 volts, so 8.7 volts is what percentage of 12.4 volts? The formula is

$$8.7/12.4 \times 100\% = 70\%$$

So **Fig. 7** shows 70% modulation.

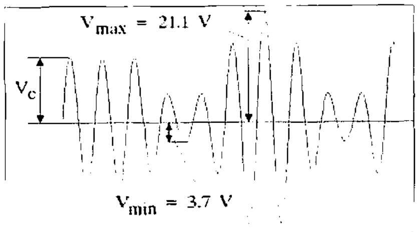

Fig. 7. Calculating the modulation percentage.

DETOUR

If you have, or can use, a PC-compatible computer, the following program lets you see a carrier with different percentages of modulation. It's written in Basic, and can run with either IBM Basic, GWBasic, QBasic, or Quick Basic:

```
10 'Program to display AM
20 PERCENT = 70 'Enter
percent here
30 SCREEN 2 : PRESET(0,100)
40 FOR X=0 TO 639
50 CARRIER = SIN(X/5)
60 AUDIO = SIN(X/50) *
PERCENT/100
70 TOTAL = (1 + AUDIO) *
CARRIER
80 Y = 100 + 40 * TOTAL
90 LINE -(X, Y)
100 NEXT X
110 IF INKEY$="" THEN 110
120 SCREEN 0
```

Enter the desired modulation percentage in line 20, and then run the program.

Line 30 of the program puts the display into graphics mode, and positions a black dot halfway down the left side of the screen. Lines 40 through 100 set up a loop to plot 640 dots across the width of the screen.

At each of the 640 positions, line 50 calculates a carrier voltage, line 60 calculates the audio (modulation) signal, and line 70 puts them together. By multiplying the two, it uses the value of the audio voltage to set the height of the carrier, and finally lines 80 and 90 calculate the height of the point on the screen and plot it. 73

END OF DETOUR

The BEARS Hunt the Fox

Motivate, mobilize, and make it fun!

Pete Kemp KZ1Z
Bethel Educational ARS
Bethel Middle School
600 Whittlesey Dr.
Bethel CT 06801-1594

Looking for a great hands-on activity to motivate your students? Try a foxhunt! This multifaceted event encourages students to organize, research, experiment, construct equipment, and, most importantly, to have fun.

The Bethel Educational Amateur Radio Society, the BEARS, sponsored by the Technology Education Department of the Bethel Middle School, is designed to provide co-curricular amateur radio activities for our community's youth. It's an amateur radio organization in which the students are the primary focus and the adults serve as advisors.

The BEARS students constructed 2-meter loop antennas and learned about both foxhunting techniques and the importance of attenuators. The area was evaluated for good hiding places, sweep/search patterns were visualized, and a variety of safety-related issues were discussed. A group of students developed the rules and, on the appointed day and time, the foxhunt began.

"Some parents who came by to watch have since become licensed themselves, expanding the number of ham families in our community."

Photo A. Jason Strano N1JSW (l) and Bill Noyce N1LGU (r) check out a DF loop.

Many of the students got into the spirit by wearing military and camouflage clothes, which provided some hikers in the area with quite a thrill. Seeing the bustle of activity, they actually thought that this group was on a real search-and-rescue mission! Many people stopped by the Command Center to ask questions, and to request information on amateur radio licensing and classes.

The Fox Team was given a 15-minute head start. They used a dual-band HT for 2 meters and 220 MHz and a variety of antennas, from stubby ducks to a full-waver. They also had extra battery packs. The BEARS maintain the local 224.32 MHz repeater, so we were able to use 220 MHz as a backup and to coordinate events behind the scenes in case any problem cropped up. The 224.32 repeater has an autopatch, so we would be able to contact parents or emergency services if necessary.

It is important that a Fox Team have speaker-microphones or headsets, as in-close foxhunts require sharp hearing and you don't want to give away your position by talking loudly. While the Fox Team was getting ready to settle in, a review of rules took place, maps of the area were passed out, and an opportunity to address any last minute questions or concerns was provided.

In the interest of personal safety, all teams were comprised of three or four members. The more teams the merrier! Younger BEARS members were assigned to teams with at least one adult member.

"This multifaceted event encourages students to organize, research, experiment, construct equipment, and, most importantly, to have fun."

The hunt is on!

With the Fox Team safely hidden in the woods, the intrepid BEARS Foxhunter Teams took off in hot pursuit, antennas banging into tree branches and flying in all directions, each team wanting to be the first to trap the fox—nothing like a little pumped-up motivation to get this activity off on the right foot. This will also do wonders for one's cardiovascular conditioning.

Listening to the radio communications on simplex was quite humorous at times, with a seemingly endless stream of requests for the fox to send out transmissions and the fox replying with cryptic clues, in addition to taunting the hunters. It took nearly an hour, but the foxes were eventually captured. In the end, common sense pulled it out for the winning team. When the signals began to swamp their receivers, some participants removed their antennas completely and ran around the area, pointing their HTs in all directions, frustrated by the fact that they knew they were closing in on their prey. The foxes were hiding in plain sight, in the prone position, their camouflage clothing blending in with their leafy surroundings. The winners actually found the fox when they stepped on him! Within the next 10 minutes all teams were on target and accounted for.

Tired, hot, and physically exhausted, the first comment made was "CAN WE DO IT AGAIN?" You bet! The Foxhunt Committee is currently looking into new locations, encouraging students to construct or upgrade their equipment and foxhunting knowledge. All participants received a Certificate of Participation, which noted that this type of event supports skills that could be used by our local RACES/ARES organization.

Since our foxhunts began in the woods four years ago they have continued to garner a loyal following, with as many as eight teams participating. Doug Griffin WA1KRX put together an excellent "Foxhunting Basics" handout and has made presentations to the students, always allowing plenty of time for full question and answer sessions.

This activity is just the type of involvement that is readily accepted by youthful amateurs and students interested in our hobby. By taking full advantage of their needs, it provides a perfect way to acquire practical amateur radio experience, and have a good time as well. An additional bonus was that some of the parents who came by to watch the fun have become licensed hams, adding to the ever-increasing amateur group in our area. Having a parent become a licensed amateur offers a number of benefits to a child. It enhances a healthy parent/child relationship, and the student is assured of getting additional equipment as well as the opportunity to get that antenna hoisted up just a bit higher. This connection also provides the school club with additional human resources; chaperones and supervisors for future events, such as Field Day, simulated emergency tests, and other public service/training events. 73

Dealing With Doublespeak

Interpreting those befuddling transceiver spec sheets.

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

Interpreting the specifications sheets used by ham radio equipment manufacturers to describe the technical advantages of their radios can often be a trying exercise. It seems as though the manufacturers have gone overboard to make them sound impressive, but it's sometimes tough to ferret out the *real* information. Mass-marketing techniques have definitely invaded the Hallowed Halls of ham advertising, using glitzy ploys previously associated with the guy or gal on-the-street consumer markets! As this trend grows, it's even more important for all of us to understand some of the finer points in the interpretation of technical specifications—more so than in years past.

Keep in mind that this treatment is intended to help clarify the numbers and acronyms used to describe amateur transceivers, not to make matters worse! So I'll attempt to use non-intimidating, readily understood terms—which, to some, may seem incomplete—but which, hopefully, will be understood by those at whom the article is aimed.

"If connecting a resonant antenna results in a background noise increase, a preamp will only bring up more background noise."

The following list contains most of the parameters quoted in the bulk of the transceiver manufacturers' technical spec sheets. I hope that I've covered those important for making purchasing and/or operating convenience decisions, but inevitably someone's favorite will be left out. Let me know—calmly, please—if that's the case.

Sensitivity

Sensitivity is a figure applied to radio frequency receivers indicating how little signal is needed at the set's antenna terminals (or coax input connector) for a minimum incoming signal to be at least "mostly" readable. It's usually referenced against so many decibels of quieting above the noise—generally 10dB. Since sensitivity is given as a voltage figure, 0.25μV for 10dB signal-to-noise ratio means that 1/4 of a microvolt at the antenna connector will produce a signal a little over 3 times the level of the background noise, a fairly typical figure. 6dB would represent a doubling of the voltage, 12dB a quadrupling of it, so 10dB would fall toward the high side of in-between, or 3.17 times.

Important: A dB of power is different from a dB of voltage; in power terms, 3dB represents a doubling and 6dB, a quadrupling of the power. In voltage terms, remember, 6dB represented a doubling and 12dB a quadrupling of the voltage (as mentioned in the previous paragraph). Nice of them to do that, but actually it's unavoidable, because power is the product of voltage and current. I mention it here so that it's not a surprise when we start to talk about power shortly.

Keep in mind that an increase or decrease in decibel terms is a ratio, and purely a logarithmic ratio, rather than a linear relationship. I think that's why many people shy away from using the dB concept, but it's not really that difficult. Using logarithmic ratios has two distinct advantages: Our senses work on a more-or-less logarithmic scale, and logarithms can be added together with the result being the same as if we had multiplied the actual numbers represented by the logarithms. Take a quick look at the sidebar chart to see how the logarithmic ratios for power and those for voltage relate. The chart also shows why it's important to figure out if the specs are speaking in terms of power or voltage, because the numbers can change quite a bit depending on the choice...and it's not always made totally clear by the specification writer.

Sensitivity, by the way, like most good things, can be overdone under certain local listening conditions. For instance, if you have a ham neighbor nearby, too much receiver sensitivity can result in overload products being developed—and those products are developed within your own receiver if it's too sensitive! In other words, a more sensitive receiver can usually be overloaded more quickly than a less sensitive one; that's the purpose of the attenuator switch found on many sets. It allows a person to deliberately make the receiver temporarily less sensitive—by a fixed number of decibels—if an overload is anticipated or is already taking place. Sometimes the RF gain control can also be effectively used for the same purpose or in conjunction with the attenuator switch.

Another point that's sometimes overlooked with regard to sensitivity is that if the background noise, with the antenna connected, is already above the noise generated within your receiver, more sensitivity won't help. It will only increase that external background noise even more. If connecting a resonant antenna to your receiver increases the noise from the speaker, then you probably won't benefit from additional sensitivity. Most modern receivers and transceivers generally have enough gain in the HF (below 30 MHz) portion of the spectrum so that they don't need additional help. Here are some of the common figures you'll see for a modern receiver or transceiver in the area of sensitivity (all for a 10dB signal-to-noise ratio): 1μV (1 microvolt) is common below the AM broadcast band,

4µV within the AM broadcast band and .25µV above the AM broadcast band through 10 meters. VHF and UHF receivers will sometimes benefit from some help, such as might be attainable via a low-noise preamp, because internally generated noise is more a problem at these frequencies. Again, it also depends upon the amount of local "normal" background noise present. 0.2µV or better in a 2 meter receiver is reasonable, but the lower the noise generated in the RF amp or preamp itself, the better. GaAsFETs are good performers in the VHF/UHF ranges and add-on preamps will usually be rated as so many dB of gain at such-and-such dB noise figure. Again, the lower the noise figure, the better; it's usually more important than gain at these frequencies. Obviously, though, an amplifier must have *some* gain to be an amplifier. A GaAsFET preamp will probably have less than 1dB noise for 15dB gain. So if connecting a resonant antenna results in a background noise increase, a preamp won't do anything other than bring up the background noise some more. The only time that this might be advantageous is if your receiver's AGC (Automatic Gain Control) circuitry is somehow lacking. In some receivers, more front end gain will improve the "AGC action," that is, the ability of the AGC circuit to maintain a "constant" output level with widely varying input signals. I've run into this in a couple of specific receivers. It may be due to insufficient RF gain, IF gain, or a problem in the design of the AGC circuit itself, but whatever the reason, adding a preamp can be a "quick fix" for a more complex design problem.

"Even a chain-link fence in the near field pattern of your antenna can generate harmonics, and they can be picked up on other frequencies!"

Selectivity

Selectivity is the figure used to indicate how well a receiver is able to separate one nearby signal (nearby in frequency) from another. It's usually determined, in modern sets, by the bandwidth of the crystal filters installed in the receiver's IF circuitry. These days they're pretty good. On SSB, the voltage gain may be down 6dB (a factor of 2:1) at 2.5kHz, while at 4.5kHz, it's probably down some 60dB (a factor of 1000:1). This is called "skirt selectivity," because the sides of the response curve slope downward much like the shape of a woman's skirt. The faster the slope, the better. Mini-skirts are better yet—no, that's another thought!

Narrower-than-normal filters are usually offered as options for "improved" CW, AM and SSB selectivity in today's transceivers. Keep in mind that "improved" selectivity means narrower frequency response and more critical tuning, so they may not seem to be improvements from every user's standpoint. Tighter selectivity will cut down on interfering signals, without question, but they also alter the "naturalness" of the final sound to some degree—sometimes to too great a degree, but it's a personal preference. IF shift—shifting the received signal within the receiver's intermediate frequency passband—is another, often less drastic way to cut down on interference. To my ear it's not as "limiting" as tighter selectivity for SSB reception. It's an arguable point. I'm not a big fan of reduced selectivity for the voice modes, because of the limitations on intelligibility, but for CW and Data, it's often a "must" on our crowded HF ham bands.

Emissions and harmonics

Spurious emissions and harmonic content refers to the number and strength of harmonics or other unintended (unwanted) signals emanating from a individual's transmitter. Most modern transceivers are quite good, listing figures of more than 40 to 50dB down in terms of harmonic output. It's a power ratio, by the way, so -40dB is 10,000 times down; -50dB would be 100,000 times down from the rated output power in watts. That translates into .01 watt (10 milliwatts) to .001 watt (1 milliwatt) of harmonic output for a 100 watt transceiver. They have to be that good to pass FCC guidelines for sale in this country, but there are things that a ham can inadvertently do to "degrade" the manufacturer's attempts to keep these unwanted products as low as possible.

Keep in mind that anything added to the transmission line after the basic transmitter or transceiver—such as an SWR bridge or a linear amplifier—can degrade those figures. SWR bridges have diodes that can sometimes create harmonics that weren't there before, and amplifiers can run nonlinear if overdriven to varying degrees. Need something to keep you awake nights? Even rusty crossover points in a chain-link fence, in the near-field pattern of your antenna, can generate harmonics by iron oxide diode action, and they can be picked up by nearby receivers tuned to other frequencies! It is incumbent upon the licensed operator to correct or minimize unwanted emissions, regardless of origin.

Spurious response

Spurious response is the measure of a receiver's ability to handle a strong local signal and to not generate unwanted byproducts as a result of that exceptionally strong signal. Take another look at the discussion on receiver overloading under the topic of sensitivity above. There are inherent design approaches that a receiver manufacturer can take—including the choice of components in the first stages (the RF amp and mixer stages) of the receiver—to minimize this

Specifications

General

Rx frequency range: 100 kHz - 30 MHz

Tx frequency ranges: 160 -10m amateur bands only

Freq. Stability: < ± 10 ppm (-10 ~ +50°C)
< ± 2.0 ppm (0° ~ +50°C) w/TCXO-4
< ± 0.5 ppm (0° ~ +50°C) w/TCXO-6

Freq. Accuracy: < ± 7 ppm (except FM, < ± 500 Hz)
w/TCXO-4: < ±2 ppm (FM < ± 460 Hz)
w/TCXO-6 < ± 0.5 ppm (FM < ± 500 Hz)

Operating temperature Range:(-10° ~ +50°C)

Emission modes: LSB, USB, CW, FSK, AM, FM

Frequency steps: 0.625/1.25/2.5/5/10 Hz for SSB, CW, RTTY & Packet; 100 Hz for AM and FM

Antenna impedance: 50Ω unbalanced

Power consumption:

Input	Rx (no signal)	Rx (signal)	Tx (100W)
100~125 VAC	70 VA	80 VA	550 VA
200~240 VAC	80 VA	90 VA	600 VA
13.8 VDC	2.4 A	2.8 A	19 A

Supply voltage: 100~125, 200~234 VAC, 50/60 Hz

Dimensions (WHD): 410 x 135 x 347 mm

Weight (approx.): 15 kg. (33 lbs)

tendency. IF rejection and image ratio are included under this general heading, though they may he stated separately, and good figures (in voltage terms) are -70dB or better, which is in the order of a 3000:1 reduction, voltage-wise.

Other parameters

Squelch sensitivity used to be generally thought of in terms of FM receivers only, but many SSB/CW receivers today also have squelch capabilities. In general, squelch sensitivity refers to the minimum signal required to "open" the receiver's squelch circuit, allowing the operator to hear a call from another station. The setting of the squelch control itself, of course, will also affect the ultimate sensitivity of the receiver to "open up" upon the presence of a valid signal, but the absolute minimum signal needed is a factor that's built into the receiver's capabilities. Many show figures of .25µV (1/4 of a microvolt) or less, which is quite sensitive.

Carrier suppression refers to how far down the unwanted carrier, in single-sideband, is from the carrier in, say, the CW key-down position. Getting rid of as much of the carrier as possible is the idea, since the carrier contributes nothing to an SSB signal, other than perhaps more QRM if it's too high. Today's balanced modulators easily cut the carrier down to -40dB or more, a factor of 10,000:1 or better. That's still .01 watt (10 milliwatts) of carrier for a 100 watt transceiver, which explains why you'll often hear some carrier from a nearby station.

Unwanted sideband suppression is pretty much a factor of the selectivity of the fixed crystal filter used to filter out the unwanted sideband in an SSB signal. It's done at a low power stage and generally runs better than -40dB, about the same as the carrier suppression. And for the same reason as good carrier suppression is important, good sideband suppression lowers unnecessary QRM on the bands.

Frequency stability is generally very good today, compared with the Tube Era, but it still varies from one transceiver model to another. Within plus or minus 200Hz over a 30-minute period and plus or minus 30Hz thereafter are common figures. The less drift, obviously, the better, but you must reasonably expect *some*. Individual transceivers of a particular model number may be slightly better or worse; the manufacturer publishes averages. Keeping the transceiver cool with adequate air circulation helps a great deal. Power supply regulation can also be a factor, when using an external power supply, but today's voltage regulators are excellent as long as the supply isn't overloaded. Battery operation, without the benefit of recharging the battery, may be one area where frequency stability can suffer, even today. You can reach a point where the regulators in the transceiver no longer have enough "head-room" voltage to work with—I've heard it a few times from stations running from emergency battery power only.

"The human factor counts—some mikes sound very different depending on who's speaking."

Microphone input sensitivity and impedance are two specifications that are sometimes glossed over, but they can be important if you're not using the microphone made to match a specific transceiver. Here's why: Amateur transceivers can vary a fair amount in their audio input impedances. Back in the all-tube era, ham transmitters had "high impedance" mike inputs—100k to 1 megohm. The switch to solid-state transceivers saw mike inputs in the "medium impedance" (2k to 10k ohm) and "low impedance" (500 to 2k ohm) ranges; most fall into the "low impedance" spread these days. Transceivers also vary in their input audio sensitivity, from -80dBm to perhaps as high as -20dBm (dBm is a standard of 1 milliwatt into 600 ohms). Of course, the mike plug, its wiring, and whether the audio "ground" and PTT "ground" are the same point within the transceiver's internal circuitry will vary from manufacturer to manufacturer.

Often, the choice of microphone can make a substantial difference. It depends upon the frequency response of the mike itself, the internally-determined audio frequency response of the transceiver and the individual voice characteristics of a particular operator. How the operator handles the mike (mouth-to-mike distance and the strength of his voice) are also factors; some mikes sound quite different when "close-talked." All of the other specifications we've mentioned are moot if the person on the mike can't be heard at the other end of the circuit!

If you intend to use an existing mike with a new transceiver, it's best to check the specs of the new radio against those of the existing mike to be sure that they're compatible from an output level and impedance standpoint. An *exact* impedance match isn't necessary, since most transceivers have a microphone gain control to compensate for inequalities in the various mike outputs and human voice-loudness differences, but you'll need to be in the right ballpark. It's also important to have the correct DC voltage available at the mike connector for driving an electret mike's built-in FET preamp, if that's the type of mike you intend to use.

Audio power output and impedance indicates the amount of audio driving power that can be expected to be developed into a particular speaker load impedance without developing more than a certain percentage of distortion. A typical figure for an HF transceiver would be 1 to 1-1/2 watts, at 10% or less distortion, into a 4-ohm speaker. That will fill your shack with more 20 meter chatter than you'll probably tolerate for very long! Hand-held transceivers will put out only a half watt or so of audio at 10% distortion, but it's enough to make the small internal speaker in an HT begin to rattle. Audio power, output power, and impedance are more important if you intend to run extension speakers to other locations, or if you're using a relatively inefficient external speaker that may require more driving power.

Final power is something that shouldn't be confusing, but often is. In HF transceivers, it's usually given in PEP (Peak Envelope Power), input power in watts for SSB, and DC input power in watts for CW, FM and AM. Some VHF/UHF transceivers have chosen to state the output wattage instead. In cases where the RF power is stated in input terms, the output to your antenna (or linear amp) will generally be only 50 to 60% of that input figure; that's the conversion loss experienced between input DC power and output RF power. A transceiver that quotes 200 watts DC-CW key-down power input will actually read about 100 to 120 watts on a

WATTAGE	VOLTAGE
+100dB = 10,000,000,000	+100dB = 100,000:1
+90dB = 1,000,000,000:1 (1 billion to 1)	+90dB = 31,700:1
+80dB = 100,000,000:1	+80dB = 10,000:1
+70dB = 10,000,000:1	+70dB = 3,170:1
+60dB = 1,000,000:1 (1 million to 1)	+60dB = 1,000:1
+50dB = 100,000:1	+50dB = 317:1
+40dB = 10,000:1	+40dB = 100:1
+30dB = 1,000:1 (1 thousand to 1)	+30dB = 31.7:1
+20dB = 100:1	+20dB = 10:1
+10dB = 10:1	+10dB = 3.17:1
0dB = 1:1	0dB = 1:1

***Table 1.** This chart might be a handy thing to keep nearby for the numerical ratios you'll need to know.*

wattmeter connected directly to its output, when the transceiver is connected to its proper terminating impedance (usually 50 ohms). The FM and AM outputs are often considerably less. By the way, the FCC considers you responsible for knowing your output PEP (Peak Envelope Power)...if you're operating anywhere near the legal limit—and the legal limit is just 200 watts PEP on certain bands and subbands. Peak Envelope Power output is different (greater) than CW key-down power output; it must be measured because of differences in individual voices, speech circuits, speech processors, microphones, etc. Take a look at a recent copy of the FCC Rule Book for the entire story. Peak Envelope Power must be read with a scope or a PEP meter. The average wattmeter may not be fast enough to catch the peaks in the RF envelope.

Power requirements will either be quoted in terms of 120 volts or 240 volts AC, at so many watts, in the case of a transceiver with a built-in AC power supply. For transceivers intended to work from "12 volts DC," the normal CW key-down amperage will be given for the transmit mode and the "normal listening level" current for the receive mode. Make sure that the 12 volt power supply (if one is used), its wiring, fuses, and any connectors in the circuit will safely carry the expected maximum current drain.

Here's another point to keep in mind: The commonly used term "12 volts DC" probably means 13.8 volts DC. Why? Because 13.8 volts is what a fully charged lead-acid (automobile) battery can be expected to deliver. During charging, that figure may rise to 14.4 volts. It's important because if that is the voltage level that the manufacturer uses in his specifications, then your fixed-station, low-voltage, high-current power supply should also deliver that 13.8 volt figure. Some transceivers won't regulate properly internally with much less in the way of terminal voltage. Try to measure the transceiver's input low-voltage right at the rear apron power connector, under full CW key-down load, to give you a better idea of the true DC voltage input.

Et cetera

Most of the other specs listed in the literature are more or less obvious, transmit/receive frequency range, antenna impedance, modulation type/s, number of IF conversions and the IF frequencies used, etc. They rarely require much translation. Most of us get hung up on the decibel business, so I've concentrated on those specifications more, with others that I felt were of importance added to the discussion.

Some additional thoughts

It's possible that some of the most important specifications aren't even given...at least those that I feel are pretty important. I'd like to see a typical frequency response curve for the transmitter's audio section, so that I'll know where to start if I receive reports dio sounds "tinny," or too "bassy." On the same topic, I'd like to see a response curve for the receiver's audio circuits. I've heard of receivers that can cause operator fatigue, over a long operating period, simply because their receiver audio chain wasn't designed for overall listener comfort. I would also like to see a figure on the minimum DC input voltage that's allowable into a transceiver, when the internal voltage regulators begin to lose control, as discussed under the power requirements section above. More information on AGC attack times and recovery rates would also be helpful—these are usually only apparent after operating a transceiver for a while. Smoothness of tuning and accessibility of often-used controls are also important features. The "logic" of how memories are stored and retrieved can make operating any particular transceiver either a pleasure or a chore (there are those of us who still like a button that does just one thing, and is clearly marked as to what that one thing is).

Admittedly, some of these are "human-engineering" issues, which are often difficult to phrase for data sheets, but they're issues that can make or break a particular model's acceptability in the "real-world" marketplace. Rest assured that the manufacturer will inevitably promote the best features and avoid those that might prove to be embarrassing; I suppose that's only natural.

Phrases like Auto Correlation and Adaptive Digital Filtering are just now beginning to appear in advertising literature, but be prepared for an onslaught of new multi-initialed acronyms...then try to understand what they're really saying. The smoke hasn't begun to clear yet, but I hope that the various transceiver manufacturers can get together on what to call things and on what are the issues important to the rest of us out here. Until then, the Decimation Aliasing and Correlation Products will keep us Quantizing the transceiver ads! Rough translation: We'll keep trying to wade through the number of confusing ads and repetitive word-speak, to a finite number of specifications having some degree of precision in their common usage.

In the meantime, remember that anytime you're reading specs, try to determine whether the writer is talking in terms of

voltage (two times increase = 6dB) or wattage (two times increase = 3dB)...it can make a world of difference in what the real specification means. It isn't always easy to determine, nor is the reference dB that the writer might be using always the accepted standard, but most specs are referenced against: 1 milliwatt into 600 ohms for wattage (called a dBm) and 773 millivolts into 600 ohms for voltage (called a dBV). For true dB gain comparisons, the input and output impedances must also be equal.

See the sidebar chart for decibel (dB) ratios from zero dB to 100dB for both wattage and voltage. Notice the logarithmic rise in both, but differing for wattage and voltage.

The same ratios apply in the negative direction when calculating dB below zero. As an example: a +60dB increase in wattage would be a 1 million to 1 increase, a -60dB decrease in voltage would be a 1,000 to 1 decrease.

FYI: Please send 73 your filled-out Feedback card...73 Magazine values your input...(plus there's a drawing from the cards received for a free subscription too.) Tnx. Last month's winner: Phil Licwinko of PA.

SPECIAL EVENTS

Listings are free of charge as space permits.Please send us your Special Events two months in advance of the issue you want it to appear in .For example, if you want it to appear in the April issue, we should receive it by January 31. Provide a clear, concise summary of the essential details about your special event.

MAY 26

WEST FRIENDSHIP, MD The Maryland FM Assn. will hold their Hamfest al Howard County Fairgrounds. Talk-in on 146.76, 224.76, and 444.00. Contact *Melvin Seyle WA3KZR, 15809 Pointer Ridge Dr., Bowie MD 20716. Tel. (301) 249-6147.*

MAY 31, JUN 1–2

ROCHESTER, NY The Rochester Hamfest and Computer Show, combined with the New York State Atlantic Div./ARRL Convention, will be held at Monroe County Fairgrounds, Route 15A. Schedule: Fri., May 31st: 6 AM Outdoor Flea Market. 6:30 PM: Annual Banquet. Sat., Jun. 1st: 8:30 AM–5:30 PM: Exhibit Hall Open. Sun., Jun. 2nd: 8:30 AM–1:30 PM: Exhibit Hall Open. 1 PM: Grand Award. The outdoor Flea Market runs continuously all weekend. Accommodations at the Rochester Marriott Thruway Inn, P.O. Box 20551, Rochester NY 14602; Tel. (716) 359-1800. You MUST tell them you are with the Rochester Hamfest. For accommodations at other hotels, airline tickets, car rentals, call the Hamfest official travel agency, Gallery of Travel, (800) 724-2046 or (716) 427-0920. There is no charge for the agency services. Talk-in Rptr.: 146.28/.88. Contact during business hours, *(716) 424-7184.* For ticket info, call *(716) 671-4430 before 9 PM.Internet:http:// www.vivanet.com/-rochfst/hf/ main96.html.Email: rochfst@vivanet.com.*

JUN 1

FRIENDSHIP, WI A Spring Hamfest will be hosted by the Adams County ARC, 8 AM–2 PM al Adams County Fairgrounds. Setup is at 7 AM. VE Exams. Tailgate selling area available. For details, contact *Adams County ARC, P.O. Box 232, Friendship WI 53934. Tel. (608) 564-7887; Packet: N9TD-1 on 145.03.* Talk-in on 145.29 Adams Rptr.

LOVELAND, CO The Northern Colorado ARC will sponsor "NCARC Superfest" at the Larimer County Fairgrounds, 700 S. Railroad, 8 AM–3 PM. Talk-in on 144.515/.115 PL 100; or 146.25/.85. For VE Exam and table info, call *Jeanene Gage NØYHY, (303) 351-7327.* For general info, call *Michael Robinson AAØUB at (970) 282-1167.*

SPRINGFIELD, IL A Hamfest sponsored by Sangamon Valley RC will be held at Illinois State Fairgrounds, 4-H building, 8 AM–1 PM. FLEA Market. VE Exams at 9 AM. Talk-in on 147.315, 224.68, and 444.75 (all -103.5 Hz tone). Contact *Don Pitchford WD9EBK, RR#1 Box 104, Springfield IL 62707. Tel. (217) 789-4519.*

TEANECK, NJ The Bergen ARA will hold its annual Spring Hamfest at Fairleigh Dickinson Univ. Flea Market, reservations required for power. The VE Exams contact is *Bob Neukomm, (201) 427-3568 before 10 PM.* Hamfest contact is *Jim Joyce, (201) 664-6727.*

JUN 2

CHELSEA, MI The Chelsea ARC, Inc., will hold their 19th annual Hamfest/Swap 'N Swap at Chelsea Fairgrounds, starting at 8 AM. Setup is at 6 AM. Talk-in on 146.980 Club Rptr. No VE Exams. For more info, contact *Alan Robbins, 3800 Hooker Rd., Pinckney MI 48169. Tel. (313) 878-0363.*

CONTOOCOOK, NH The Contoocook Valley RC will hold a Flea Market starting at 8 AM, Exit 7 off I-89, 14 mi. NW of Concord. Talk-in on 146.895(-) or 146.94(-), and 146.52 simplex. For details, call *John Moore N1FOJ, (603) 746-4817; or Packet BBS: WA1ALM @ WA1WOK.*

CORAOPOLIS, PA The 42nd annual Breezeshooters Hamfest and Computer Show will be held at the Butler Farm Show Grounds. 8 AM–4 PM. Table selection is on a first-come-first-served basis, so apply today. Contact *George Artnak N3FXW, 3350 Appel Rd., Bethel Park PA 15102. Tel. (412) 854-5593.* Indoor tables must be reserved before May 20th. Product demos by ICOM America. Mobile check-in until 2 PM: 28.495 and 146.520 MHz. Talk-in on 147.96/.36 W3UDX Rptr., courtesy the Butler County ARA.

FENTON, MI A Hamfest/Computer Fair will be held by the Fenton Area ARA. 8 AM–2 PM, at Ben Sherman M.S., 14470 N. Holly Rd., Holly MI. Sat. night setup. Talk-in on 146.78(-). Reg. for VE Exams at 9:30 AM; sessions start at 10 AM. Contact *Marty WD8RCI at (810) 634-9826; FAX (810) 634-0866.* Mailing address is *F.A.A.R.A. Hamfest Committee, P.O. Box 46, Fenton MI 48430.*

MANASSAS, VA The Ole Virginia Hams ARC, Inc. will hold the "Manassas Hamfest Amateur Radio and Computer Show" at Prince William County Fairgrounds, 1/2 mi. south of Manassas, on Rte. 234. Tailgate setup 2 PM till 11 PM on Sat. Food venders must obtain prior written approval from the Hamfest Chairman. Dealers, call *Joe K4FPT, (703) 368-5424.* For general info, call *Mary Lu KB4EFP. (703) 369-2877*

JUN 8

BYRON CENTER, MI The annual IRA Hamfestival will be held at the Hudsonville Fairgrounds near Grand Rapids MI. Doors open at 8 AM; setup is June 7th after 8 PM, or after 6 AM on the 8th. Overnight camping available. VE Exams. Book reservations early if you are interested in indoor table space. Contact *Tom KA8YSM,* or *Kathy KB8KZH, at (616) 698-6627,* or write the *IRA, 562 92nd St. SE, Byron Center MI 49315.* Talk-in on 147.16 link Rptr. system.

KITCHENER, ONTARIO, CANADA The 22nd annual Central Ontario AR Fleamarket will be held at Bingeman Park. This event will be jointly sponsored by Guelph ARC and Kitchener-Waterloo ARC, Inc. Talk-in on 146.97(-), or 145.21(-). Contact *Ted Eaton VE3GJE, 102-21 Woodlawn Rd. E., Guelph Ont., Canada N1H 1G6. Tel. (519) 823-1027; Packet: VE3GJE@ VA3RWP.#SWON.ON.CA.NA. Internet:eeaton@sentex.net.*

RIVERDALE, NJ The annual North Jersey Hamfest, sponsored by Split Rock/West Morris Radio Clubs, will be held at the NJ Nat'l. Guard Armory on Newark Pompton Tpk. (Rte. 23). Talk-in on 146.985/.385 or 223.860/222.260 PL 136.50. Contact *Bernie WB2YOK, FAX/ Voice (201) 584-5399* any time; or *75503,3221@COMPUSERVE.COM.*

WINSTON-SALEM, NC The Forsyth ARC will host the Winston-Salem Hamfest, Computer and Electronics Fair at the Dixie Classic Fairgrounds beginning at 8 AM. Free camping Fri. night. RV hook ups available for a nominal fee. Open and covered tailgating. Dealer tables. Flea Market tables. ARRL VE Exams. Talk-in will be on the 146.64(-) Rptr. Visit our website at *http://www.rbdc.com/~kq4lo/ farc.htm.* Contact *Forsyth ARC, Inc., P.O. Box 11361, Winston-Salem NC 27116. Tel. (910) 723-7388. FAX: (910) 765-6656.*

JUN 8–9

ATLANTA, GA The 1996 Atlanta Hamfestival and ARRL Georgia State Convention will be held at City Hall East - Exhibition Center, 675 Ponce de Leon Ave. (across from Crackers' Ponce de Leon Park). Talk-in: W4DOC on 2 meters at 146.82. An Atlanta Police officer will provide on-site security for the nights of June 7th and 8th. Flea Market: Ham Gear, Computers, Electronics, Software, Parts, etc. VE Exams. Ladies Activities, and much more. For more details, see our display advertisement in this issue. Show hours: Sal. 9 AM–4 PM; Sun. 9 AM–3 PM. Contact Hamfest Chairman, Marty AA4RM, (404) 814-9304. For Commercial Booths, call Bill W4LFC at (770) 493-8438. You can find Hamfest info on the BBS at (770) 850-0546. Internet address: marty@aa4rm.radio.org.

JUN 9

COVINGTON, KY The Northern Kentucky ARC will hold "Ham-O-Rama '96" at the Erlanger Lions' Park. Indoor exhibit area. Outside Flea Market with setup at 6 AM. General admission begins at 8 AM. Provide your own tables. Contact *N8JMV, c/o NKARC, P.O. Box 1062, Covington KY 41012; or call (513) 797-7252 eves.* Talk-in on 147.255(+) or 147.375(+) Rptrs.

GRANITE CITY, IL The Egyptian Radio Club annual Egyptian Fest/ Hamfest, Computer Fair and Flea Market will be held at the Granite City Campus of Belleville Area College. 1/2 mile south of I-270 on Maryville Rd., 8 AM–1 PM. VE Exams. Indoor Dealer and Exhibit area. Talk-in on 146.79. Contact

Egyptian Radio Club, P.O. Box 562, Granite City, IL 62040; or call *Bill Dusenbery N9OQK, (618) 398-1456.*

MANCHESTER, MD The Hanover Area Hamming Assn. will present the Pleasant Hill Ham and Computer Show at Pleasant Hill Fire Co., 5 mi south of Hanover, on Rte. 94. The event starts at 8 AM. Talk-in on 146.895(-). VE Exams at 9:30 AM; contact *Bill NZ3J, (717) 359-7090,* or *Pat WW3U, (717) 632-4237.* Please pre-reg.

QUEENS, NY The Hall of Science ARC Hamfest will be held at the New York Hall of Science parking lot, Flushing Meadow Park, 47-01 111th St. Setup at 7:30 AM, buyers admitted at 9 AM. Talk-in on 444.200 WB2ZZO Rptr, 146.52 simplex. For info call *Arnie Schiffman WB2YXB, (718) 343-0172, eves.*

JUN 14–15

ALBANY, GA The 14th annual Albany ARC Hamfest and Georgia Computer Fair, (1995 ARRL Georgia Section Convention), will be held at the James H. Gray Civic Center, Oglethorpe Dr. (Hwy. 82) at the Flint River, Albany GA. Table fees include passes for workers. Pre-reg. before June 1st. VE Exams $6.05 per person (checks only, no cash accepted). Rooms for conducting radio and computer forums are free. No alcoholic beverages allowed. No "Adult Entertainment" type of materials allowed. Contact *William A. Shipley, (912) 439-2351 Ext. 15.* Mail payments to *Albany Amateur Radio Club, Inc., P.O. Box 70601, Albany GA 31708-0601.*

JUN 14–16

RED DEER, ALBERTA, CANADA The Central Alberta Radio League will host its 26th annual Picnic and Hamfest at the Burbank Campsite (about 8 km NE of Red Deer). There will be many activities and displays. Contact *Bob VE6BLD, 5540 54th Ave., Lacombe, Alberta, T4L 1L6. Tel. (403) 782-3438. Packet VE6BLD @ VE6RDR.AB.CAN.*

JUN 15

BERGEN, NY The 1st annual Wire Antler Contest will be in two parts. (1) Build a 10m antenna using only wire and rope. Max. length not to exceed 140 ft. (2) The operating phase will be a Sprint-style operation 1900 GMT–2300 GMT on 10m SSB, from 28.300–28.500 MHz. Logs shall be postmarked no later than 31 Aug. 1996. Send packet inquiries to *Keith KE2DI [KE2DI@WB2VPH.#WNY.NY.USA.NOAM]* or *John KF2XC [KF2XC@WB2WXQ.#WNY.NY.USA.NOAM].* NOTE: No logs will be accepted via Packet!

Number 76 on your Feedback card

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine,* Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the July 1996 classified ad section is June 12, 1996.

QSL Contest

Did you buy your QSL off a rack, or did you put some thought and creativity into it? If you think you have a winner, send it in and let us have a look at it. Who knows, it might make the cover. Well, maybe page 85 or so. Or maybe Wayne's wastebasket. If it's declared a winner, you'll get a CD of your choice of any of 26 kinds of music, as listed in Wayne's November editorial. You'll also see it in 73!

Send it to: QSL Contest,
73 Magazine,
70 N202,
Peterborough NH 03458-1107

Great ARRL Books!

AR1996 **The ARRL 1996 Handbook** includes the latest innovations in ham radio, plus all the fundamental data. $38.00

AR1086-4 **ARRL Operating Manual** Information on how to make the best use of your station, including interfacing with home computers, OSCAR, UHF-VHF. $18.00

AR4173 **Now You're Talking! All You Need To Get Your First Ham Radio License**–A complete study guide for the Technician and Novice written exam. Practical information every beginner needs is written clearly and simply and in small doses. $19.00

AR4734 **ARRL Antenna Book.** Best and most highly regarded info on antenna fundamentals, transmission lines, design, and construction of wire antennas. $30.00

AR3177 **ARRL Spread Spectrum Source Book** From a deceptively simple beginning, a group of experimenters set out to develop first theoretical and later practical systems for spread spectrum communications. This book consists of articles, papers and government reports that document the process whereby amateur spread spectrum progressed from the drawing board to the airwaves. $20.00

AR3851 **Hints and Kinks** Ideas for setting up your gear for comfortable efficient operation. $10.00

AR4653 **Companion Software for Weather Satellite Handbook** 5-1/4" MS-DOS floppy $10.00

ARRL License Manuals:
AR4181 **Technician Class** $6.00
AR4688 **General Class** $12.00
AR3274 **Advanced Class** $8.00
AR3272 **Extra Class** $8.00

AR3185 **The Satellite Experimenter's Handbook** by Martin Davidoff K2UBC Expanded and revised. Focusing on satellites built by and for the international radio amateur community $20.00

AR4645 **Satellite Anthology** The latest information on OSCARx 9 throu 13 as well as the RS satellites, the use of digital modes, tracking antennas, RUDAK, microcomputer, and more! $10.00

AR2973 **Complete DX'er** by Bob Locker W9KI Learn how to hunt DX and obtain hart-to-get QSL cards. $12.00

AR0402 **Solid State Design** Good basic information, circuit designs and applications; descriptions of receivers, transmitters, power supplies, and test equipment $15.00

AR4971 **ARRL Repeater Directory 1995-1996** Over 19,000 listings with digipeaters, bandplans, CTCSS (PL(TM)) tone chart, frequency coordinators, ARRL special service clubs, and beacon listings from 14MHz to 24GHz. $7.00

AR4661 **ARRL's Antennas & Techniques for Low-Band DXing** can be your ticket to low-band success. $20.00

AR4483 **Weather Satellite Handbook** by Dr. Ralph Taggart WA8DQT. Expanded and revised to reflect today's weather-fax satellite technology. $20.00

More Test Equipment for the Microwave Workbench

Last month I covered frequency counters and recommended some basic microwave essentials for the test workbench. This month I will expand on that idea, covering some other handy gadgets that make microwave life on the workbench more enjoyable. I have also bundled together several technical tips, including one from the North Texas Microwave Group giving recommendations on how to test GaAsFETs with a VOM. In this application Kent WA5VJB describes how to test GaAsFETs to see if they're still alive, without destroying them.

Last month I discussed the use of a Gunn diode and attenuator (**Photo A**) to provide 10 GHz frequency drive for alignment and test generation. What about other frequencies? Is the Gunn diode arrangement still viable? Well, the answer can be "yes," but most likely it's "no." It still depends on what frequency you use and what you can find at an attractive price to pull the signal generation at your desired frequency. For 10 GHz operation the Gunn generator is fantastic; for lower frequencies something else is needed.

The oscillator

The oscillator you select for other frequency operation doesn't have to be anything as exotic as a frequency synthesizer. One of those would be nice, but anything from a crystal-controlled multiplier string to a free-running oscillator at the frequency of interest would function just fine. Be aware of your surroundings and try to adapt something that you can find locally for minimal cash outlay. As amateurs, we are known as good scroungers.

If you are lucky enough to have a wide-range sweep oscillator that tunes from 1 MHz to 18 GHz in one unit, you just might want to skip this message and go read the sports page. If you're still here, let's see what you can try to locate to pull this project together from whatever surplus is available locally. What would be very good to look for is some means of obtaining frequency agility so you can test several bands using one simple device.

> **"The most economical versatile oscillator available in easy-to-obtain material is the CATV or TV tuner front end."**

To my knowledge, the most economical versatile oscillator in easy-to-obtain material is the CATV or TV tuner front end. These can be picked up from your local TV repair shop or similar facility at little or no cost. They all contain a VCO in the several hundred to 1000 MHz or so frequency range, are inexpensive (notice I did not say cheap), and provide a hefty local oscillator signal output capable of injection directly into a mixer.

I might be over-pounding my drum on scrounging used or near-new TV/CATV components. But heck, it works and the parts are easily found in scrap or in the back of almost any agreeable TV repair shop for little or nothing. If you blow up (destroy the tuner) during conversion, go pick up several more. This is not a hard object to play with. Sure, it might take a little tinkering to figure out what lead provides what voltage and control but if they can be picked up for next to nothing, what's the gamble?

The tuner will be OK for frequencies up to 1 GHz. For testing on frequencies from 902 MHz and lower, it should be very suitable. For 1296 MHz and above, you will have to build other circuitry.

Typically, an MMIC (Microwave Miniature Integrated Circuit) type amplifier is driven hard into saturation to produce nonlinear operation. This causes the amplifier to be rich in harmonic output, due to operation in the non-linear region of its curve. Overdriving an MMIC amp input is the easiest way to cause this effect. The circuit for an overdriven MMIC is the same as a conventional MMIC amp circuit; it's just that you overdrive the circuit on its input. This scheme will give you good harmonic marker generation.

Another way to generate frequencies above 1 GHz (1000 MHz), like 1296, is to use mixed products of two generators. For example, connect the TV oscillator to a mixer with another lower frequency test generator and regenerate a signal that is a product of the two generators. I tried to generate 1296 by selecting a TV oscillator at 900 MHz and combining a bench signal generator (HP-608) tuned to 396 MHz, producing 1296 on the RF port of the mixer as one of the products. This scheme works well for frequencies in the 450 MHz to 1296 MHz range, where signal generation can be a little hard to locate.

The mixer requires the capability for operation at your RF frequency. For frequencies up to 2000 MHz a Mini Circuits SRA-11 can be used at powers of +10 dBm, with oscillator levels in the +7 dBm range. There are many different types of mixers suitable for this operation that could have coaxial type connectors mounted as part of the mixer assembly.

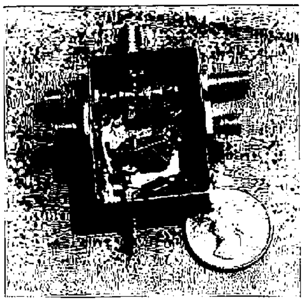

Photo B. Utility mixer for 10 GHz. The principles explained in the text can be applied to any other frequency by proper scaling of model. This circuit is actually a GaAsFET amplifier that is modified to be a mixer. See text for construction details.

The principles used in the signal generator circuit were tried many years ago when we were using WBFM simple receivers and did not have a good microwave signal generator to test them. What we did was take a microwave Gunn oscillator and use it as a local oscillator injected into the LO port of a microwave mixer. The IF port was similarly injected with a low frequency signal generator capable of operating from 10 MHz to 500 MHz. The RF port of the mixer carried the resulting products – that is, the Gunn frequency plus and minus the low frequency RF generator's frequency.

By setting the low frequency generator to, let's say, 200 MHz and adjusting the Gunn oscillator for a proper mix as detected on the receiver being tested, we were able to control the low frequency generator's frequency and level and make performance tests at 10 GHz. It's not highly calibrated in microvolt sensitivity but it does give some very meaningful evaluations of your system's performance.

Frequencies in the range of 3456 MHz and above require somewhat more complex circuitry. For 2304 operation our microwave group was lucky enough to have a supply of synthesizers, to use for local oscillator generation or test units. Normally, surplus oscillators for this range are scarce because there aren't many available. We seem

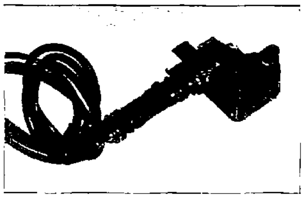

Photo A. A signal marker for 10 GHz use driven by a 2 meter HT. It produces a calibrated harmonic in the 10 GHz band for calibration purposes.

to be blessed in having two types to choose from: a Dielectric Resonator Oscillator (DRO) and a Voltage Controlled Oscillator (VCO). Both devices operate similarly, but the VCO is much more flexible than the DRO. The primary advantage to the VCO synthesizer is that it is more frequency-agile and has lower phase noise even after a multiplication of times four.

If you can't locate devices for the CATV tuner or the DRO or VCO synthesizers, I can supply any of these items for a minimal cost. The CATV tuners (new surplus) are $10 each postpaid or three for $20 postpaid. The DRO oscillators are $15 each, and the VCO synthesizers are $35 each postpaid for U. S. destinations. Both the DRO and VCO synthesizers require modifications before they can be put to practical work. If you are looking for a simple unit to experiment with, get the DRO unit. So much for oscillators.

The octopus mixer circuit

This octopus mixer is, in reality, an amplifier with added ports, allowing other frequency signals to be connected to and extracted from it. **Photo B** shows a beta test mixer. It might look a little strange with all the other coax connectors tied into the system. Basically, this unit is a 10 GHz amplifier of the single-stage variety and uses a single Mitsubishi MGF-1402 FET. Its design is straightforward: The amp input and output are isolated with 1 pF chip capacitors, and the FET is connected to input and output striplines. DC bias voltages are fed to this stripline via narrow-trace printed copper traces which act as RFCs to the 10 GHz signal. These traces (RFCs) carry the input negative bias and output DC voltage for operation of the amplifier.

"The octopus mixer is an amplifier with added ports, allowing other frequency signals to be connected to and extracted from it."

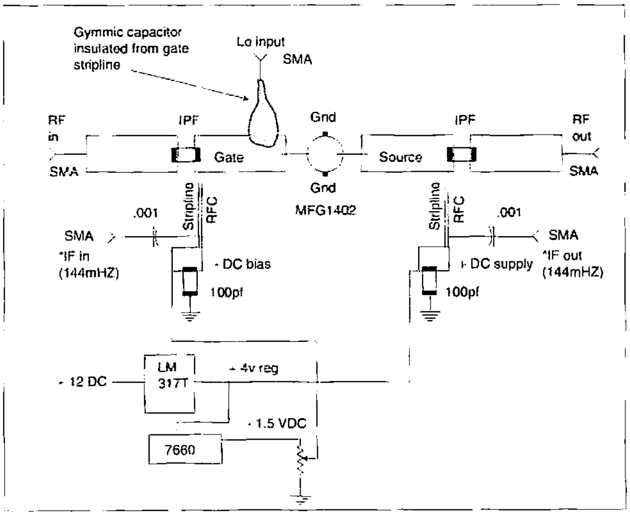

Fig. 1. Utility 10 GHz amplifier converted to a mixer configuration with additional input/output ports added. Concept is usable at other RF frequencies by adjusting size and component values, as shown in table.

RF In	IF In	IF Out	Lo In	RF Out
10.368 GHz	Ø	Ø	Ø	10.368 GHz
10.224 GHz	144 MHz	O	Ø	10.224 GHz
10.368 GHz	Ø	144 MHz	10.224 GHz	not used
Ø	144 MHz	Ø	10.224 GHz	10.368 GHz 10.080 GHz

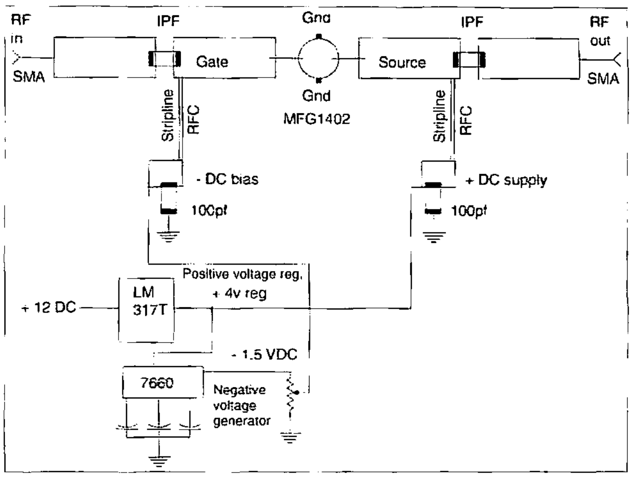

Fig. 2. Normalized schematic of basic amplifier circuit used for mixer construction as in ***Fig. 1.***

The circuitry below the FET amplifier is the positive and negative DC bias circuitry which allows the amplifier power supply to be self-contained and fed with only a single DC power input. See **Fig. 1** for the basic mixer amplifier circuitry, and **Fig. 2** for the normalized schematic of the 10 GHz amplifier before modification. The connections used in the modifications can be made applicable to any other frequency by proper scaling of the components/materials.

The mixer was equipped with many connectors to test the viability of using the amplifier as a bidirectional mixer; at the input side we could combine both an SHF and a VHF signal and have the product available on the normal output at SHF. Also, we could combine two SHF signals on the input to down-mix, setting the RF pickoff on the output to VHF by picking off RF from the RFC circuit. In this case, we would not use the normal RF output port.

Use good static prevention, namely a grounded work station. This could be anything as simple as a small chunk of copper PC board material to which everything is common grounded. That means you (wearing a static wrist strap), your low voltage soldering iron, and the amplifier to be modified. Everything is tied to the same sheet of copper, which is tied to a firm ground. (Please note: Your wrist strap contains a high resistance protection for your safety. You are not connected directly to ground. The high resistance provides a measure of protection in case the circuit accidentally connects to a foreign high voltage or AC. The wrist strap's purpose is to bleed off static charges, not pass power.)

The amplifier modification is carried out by first attaching extra connectors to the case so that you can connect input and output probes to the amplifier. If the amplifier you modify is lower in frequency it will be easier, as the size of the circuitry increases as frequency is lowered. Position the connectors in a similar fashion and experiment with the positioning of connections.

The marker generator

Another adjunct that can be very useful with microwave operation is a marker generator, which allows you to calibrate the operational frequency. This is especially useful if the equipment being used is simple wideband FM Gunn-type transceivers. These WBFM transceivers are not very stable, but they do provide an entry method into the microwave communications world for little expense.

The marker is nothing new and is not difficult to construct. It is made by obtaining a waveguide detector mount with a 1N23-type diode and driving this diode with RF power (100 mW) on a frequency of 146 MHz. The diode

rectifies and acts like a varactor, producing harmonics of the fundamental frequency. In this case, the driving power is a 2 meter HT on low power (FM) and the waveguide structure kind of supports the harmonics in the 10 GHz range. Now locating a frequency with an uncertainty of 146 MHz error is no problem at all. You don't have to worry about being off frequency by that much with simple equipment. This is not to say it couldn't happen, but it is unlikely.

Why use exactly 146 MHz for this test? Well, the 70th harmonic of 146 MHz is exactly 10220 MHz. This frequency is one of the main WBFM frequencies targeted for WBFM (Wide Band FM) operation. The other frequencies are 10250 and 10280 MHz. Notice that they are separated from each other by 30 MHz. This is due to the simple structure of the transceivers, which use each other's local oscillator to mix in the detector diode receiver and produce a 30 MHz offset of IF amplifier signal.

The harmonic calibrator can be improved greatly by replacing the 1N23-type diode with a varactor which is much more efficient in generating harmonics than the 1N23 detector. Don't forget to provide a ground return for the diode, using an attenuator between the transmitter and the diode. Most 2 meter transmitters have a 100 mW low power option switch, which in dB is +20 dB. All that is required is +10 dB, so a 5 to 10 dB pad (attenuator) needs to be connected coaxially between the antenna of the HT and the detector mount.

The RF sniffer circuit

The next handy item in the RF arsenal of tools on the bench is an RF sniffer circuit. It's basically a 50 ohm load sampled by a diode detector and tied to a sensitive meter. Use a meter amplifier for higher sensitivity. This can be nothing more than a terminated coax connector sampled by a diode detector then bypassed and fed to a low current microamp meter. If you connect a short antenna to the input connector it will serve as a (relative) field strength meter, and by making direct connection to the coax connector it will serve as a relative low power meter. This power meter can be used to tune up small oscillator strings or other RF low power output circuits, taking the place of commercial microwave power meters. The calibration and frequency response is always subject to construction differences and materials used. However, it can still be a good set of eyes up to 2 GHz or so for an indicator until you can actually calibrate it. Even if not calibrated, it will show you tuning adjustment indications.

You don't have to go through that exercise if you have a mixer available for your conversion. It is nice to know that there is some other method that can produce the same results, and even provide some extra gain in the process. Don't be embarrassed to try a new idea just because someone says it can't be done. If you haven't got anything to lose, give it a shot. You might come up with some new and enlightening idea. Be inventive; use the junk box and take a look at some of the circuitry that exists there—it can save you a lot of bucks.

As always, I will be glad to answer questions pertaining to this and other amateur-related topics. Please send an SASE or drop me a line on the Internet (clhough@aol.com). 73 Chuck WB6IGP

Sweating the small stuff

If you've been working on radio, audio, video or computer gear at all for the last few years, you've undoubtedly noticed that your eyes were going bad and you were getting clumsier. Wait a minute, it isn't you; the circuitry is getting smaller and smaller, almost to the point of absurdity! Let's face it, we've all come to expect two-pound camcorders, CD players barely bigger than the discs they play, and high-powered Pentium and PowerMac computers we can plop into our briefcases.

Ham radio has gone the same way, especially in the walkie category. Just a few years ago, the ICOM IC-2AT was the standard 2 meter handheld. When it came out, the radio seemed a marvel of miniature engineering. Heck, you could hold it in one hand with no trouble at all. Many of these radios are still in use today, but they look positively huge, as do all the handhelds of that time. Even the Kenwood TH-21AT, the smallest HT of its day, doesn't look so darned small anymore. Our concept of small sure has changed! Although HF radios have until recently resisted the "small is beautiful" concept, they too are beginning to yield, with new 100-watt HF rigs no larger than the 2 meter mobiles of four or five years ago.

SMT/SMD

If you want to fit a dual-band HT with 50 memories, CTCSS encode/decode, digitally coded squelch, and all the rest of the goodies into a 2" x 3" x 1" box, you just can't wire it up on an old-fashioned, single-sided PC board, using regular parts and hand soldering. Nobody has hands that small or vision that good.

To get our gadgets to the size scale we have now, manufacturers had to invent a whole new way of making things. There were two keys to miniaturization: the integrated circuit, or IC, and SMT, or "surface-mount technology." The actual parts used in SMT are called, naturally enough, "surface-mount devices," or SMDs. Quite often, you'll see the terms SMT and SMD used interchangeably.

SMT made things smaller for several reasons. First, the parts didn't have wires sticking out, so they didn't need places on the components to mount them. Second, because they were mounted on the surfaces of PC boards, no holes had to be drilled through the boards, so designers could run other conductors behind the parts, either on the other side of the boards or *inside* them! Inside? Yup, I'm afraid so. Many of the mini wonders we so covet are made with triple- and even quadruple-layer boards. Of course, it's possible to make such boards for use with lead-mounted parts, but it's much harder, because the internal traces have to be routed around all those holes. With SMT, it's clear sailing all the way.

But how?

Although early surface-mount parts weren't much smaller than their lead-mounted predecessors, the parts quickly began to shrink. Even the larger ones were pretty hard to hand-mount, but today's "grain of salt" resistors can hardly be seen, let alone placed by hand.

Robotics provided the answer. A robot could operate with much greater precision than could a human, and it wouldn't get tired and start making mistakes, either! Pretty soon, robots were building most of the boards in our toys. In many cases, manufacturers consider these boards unrepairable; if it stops working, the board is replaced.

Can I fix it?

That leaves us hams in an odd predicament; we want tiny radios, but they're very hard to work on,

and fixing our own gear is supposed to be part of this technical hobby. Many hams are intimidated by SMT, and with good reason. Can you successfully repair or modify a radio made from SMDs? Yes, but I say that with some reservations. For many people, the size scale of modern radios is just too small. Let's take a look at working with surface-mount devices.

First of all, you'll need some new tools. You just can't tackle a microminiature radio with a 100-watt soldering gun! Even your trusty 30-watt pencil with its 3-millimeter tip is way too big. For SMD work, you need a 1 mm or smaller tip and about 15 watts of heat. Radio Shack™ has SMD tips for some of their guns, but you have to special-order them. Also, you need some very fine solder and narrow desoldering braid. Don't skimp and omit the braid; it's a crucial tool for this kind of work.

Even if you have good eyes, you will need some magnification to work at this size scale (besides, if you don't use a magnifier, you won't have good eyes for long). A head-mounted magnifier is extremely helpful. Also, get one of those little pocket-sized telescope/microscope combinations, if you can still find one. An alternative is a pocket microscope intended for the examination of phonograph styli (remember those?).

Very small screwdrivers are a must here. Trimpots and trimcaps are tiny now too, and you can't adjust them with normal-sized tools. A jeweler's screwdriver set is very useful.

"We want tiny radios, but they're very hard to work on, and fixing our gear is supposed to be part of this technical hobby."

Getting started

Although SMT boards are built with a special, low-temperature solder, you can use regular solder on them, as long as you're careful not to keep the iron on the board long enough to damage the traces. In keeping with the size of the parts, many conductors on these boards are ridiculously small, and they'll peel up if they get too hot, ruining the board. It's darned near impossible to fix it once that happens, especially if the board is multi-layered.

So, all soldering to a surface-mount board should be done very quickly and carefully. Of course, you don't want to make a cold connection, so you do have to keep some heat on the board for a few seconds. But, the old days of slathering on the solder until you have a big blob are over (not, of course, that anyone should ever have done that, but I've seen plenty of it). If you need to desolder, though, you may need your old 30-watt iron (but not the gun!). There's a great danger in trying to desolder without enough heat, in that you can pull traces up when you pull the braid away, because it gets soldered to them. The end result is just as bad as if you'd overheated them.

Although SMDs seem to take a surprising amount of heat without self-destructing, they are so small that the heat quickly makes it to the opposite connection, leaving you with a moving part when you didn't expect it. It can be mighty hard to get the part back where it was. A small screwdriver to hold it down can save the situation. If you get an SMD too hot for too long, the metal ends which provide the connections can dissolve, leaving you with a useless part. I've seen that happen more than once.

But what is it?

Now that we've looked at soldering SMDs, it might pay to know what it is we're soldering! Unlike good ol' "regular" parts, most SMDs have no markings on them; there just isn't room for any numbers. Some of the larger resistors have Japanese-style metric markings, like "103" for 10k ohms (that's a one, a zero and three more zeros), but don't be surprised to see tons (OK, milligrams) of unmarked parts. Here's a clue, though, as to how to identify at least some of them: The black ones are usually resistors, and the tan and green ones are capacitors. Polarized electrolytic caps are generally a bit bigger than resistors, and there will be a polarity marking on the parts. You may see some obvious resistors, with round bodies and color codes, but those are old parts; the latest stuff is all tiny, square and flat. Trimpots and trimcaps still look like they always did, only much smaller. Be careful turning them, because they can't handle much oomph. Transistors have two "leads" (stumps, really) on one side, and a third on the other. The single one is usually the collector.

Beyond these general guidelines, there really isn't that much different about SMDs. Some of the ICs, with their 64 or more leads, can be darned near impossible to change. It's rare, though, that you might need to do that. SMT is very reliable, with the most common problem being bad connections, particularly to the leads of ICs. I've seen many cold connections cause trouble. The hard part is soldering the leads without causing massive solder bridges, even if you were good at soldering standard components. If you must solder leads on one of those "millipede" ICs, try not to solder very close to the chip's plastic casing, because solder can get underneath, and it's mighty hard to remove it. If you do make some bridges (which I guarantee you will), use the desoldering braid across the entire bridge at once. Usually, that'll leave you with nice connections but no bridges. For that, you may need to use your bigger iron (but not the gun!).

Not for beginners

If you're new to electronics work, I recommend you stay away from SMDs until you're more experienced with normal, leaded parts. Even for old hands, this new technology is presenting challenges, especially as the parts get smaller and smaller. I was pretty good with the earlier SMDs, but the new ones are starting to reach my limits. If they get any smaller, I doubt I'll be able to work on them.

'Til next time, 73 de KB1UM.

UPDATES

Can't seem to get those ducks in a row...

In Sam Ulbing N4UAU's "Tiny Tic-Tac Tester" article, *73*, March 1996, regarding the component values for battery chart—all columns should have lined up: Alkaline cells numbers should have been placed directly below the numbers for NiCad cells. It seems we missed something in making that chart.

Translation bollix?

In the April "Carr's Corner," in the second column on page 60 the values 50W, 5,000W, and 600W appear. These W (watt) values should all be Ω (ohms). In the original manuscript, they were correct, but for some reason, the Ω symbols all metamorphosed into Ws. The "200 watts" in the paragraph that follows is correct.

Also in April's issue, we began "Debunking Some Myths about Antennas, Feedlines & SWR" on page 40 and promised to continue it on page 59. **Toon 2** in the bottom right hand corner of page 59 is the second part of that article which is again continued on page 81.

Also on page 59, the two columns of "A Simple One-Hour" that claims to have been continued from page 40 should not be there. It is actually the specter of an article published months ago.

Author's update

Here's a tip from Marty Gammel KAØNAN for those of you who are having trouble finding the 3/16" copper tubing described in April's "440 Super J-Pole" article, and also May's "220 Super J-Pole" article. Go to the electrical department of your local building supply and ask for some #6 solid copper ground wire. The diameter is quite close to 3/16", and it works well as a substitute. It also bends more easily. (Its price should be about the same as the tubing.)

Coaxial Cable

Get comfortable with it.

George Wilson W1OLP
82 Fraiser Way
Marstons Mills 02648

Of the many different types of coaxial (coax) cable, only a few are used by the average radio amateur. These have 1/4" and 1/2" "nominal" diameters. The 1/4" types vary from 0.195" to 0.262" in diameter and require different adapters when used with UHF and BNC connectors. The popular 1/2" cables are 0.405" in diameter. A 1/10" (0.100") diameter type is also popular. It's used for filters and resonant lines, most often within project enclosures.

Both 1/4" and 1/2" types are available in nominal 50- and 72-ohm impedances. Half-inch cables can handle more power and have less RF loss than the 1/4" types. Coax cables handle power best when they are operating at a 1:1 VSWR.

The table at right contains some useful information on popular coax cables. Published data (in the handbooks) on coax line loss and power handling capability all assume that the cable is operating at 1:1 VSWR. Additional line loss, and less power handling capability, occur if the cable is not operating at or near 1:1 VSWR.

The dielectric in many coax cables is foamed polyethylene. These cables are lighter, more flexible and less expensive than solid dielectric types. Although they were often disparaged when first introduced, time has shown that most of the criticism was reactionary—people do not like changes. The ends of solid or foam cables should be sealed against moisture when used outdoors. Radio Shack™ 278-1645 sealant (tape) works well.

The Velocity Factor (VF) for the cables is shown in the table. This tells how much shorter a cable should be to be equivalent to the wavelength in air. This factor is of use when making filters (typically, stubs on coax lines to reduce unwanted signals), and when making stacking harnesses to operate more than one antenna from the same feedline. There are experimental methods of determining the exact VF of a particular line, but the published data is fine for most applications.

"Foam cables were disparaged when first introduced; time has shown that most of the criticism was reactionary."

Most ham rigs have 50-ohm input and output impedances, so it has become accepted practice to use this impedance between the various devices used in our ham shacks. In fact, since the VSWR and power loss are acceptable, 50-ohm cable is often used to feed resonant dipole antennas that have 72-ohm balanced (coax is unbalanced) impedance. Over the years, feeding balanced antennas with unbalanced coax lines has become normal practice. The 72/50 mismatch causes a VSWR of less than 1.5:1, with a short-run loss of less than 10% more than a matched line. This power loss is barely noticeable on a receiver's S-meter. A balun at the antenna may be used to help eliminate RF on the outside of the coax, consequent RF in the shack, and distortion of the antenna's radiation pattern.

50 Ohm Types*	Velocity Factor (%)	Outside Diameter (")	Dielectric Type (**)
RG8, 8A, 213	66	0.405	
RG8X	75	0.242	Foam
RG8 Foam	80	0.405	Foam
RG58, 58A, 58C	66	0.195	
RG58 Foam	80	0.195	Foam
72 Ohm Types**			
RG11, 11A	66	0.405	
RG11 Foam	80	0.405	Foam
RG59, 59B	66	0.262	
RG59 Foam	79	0.242	Foam

**Impedances shown are nominal*
***Dielectric type is solid polyethylene unless marked "foam," in which case it is foamed polyethylene.*

Pylon Mobile Mount

A quick way to install your car rig.

Jim Gray W1XU
210 East Chateau Circle
Payson AZ 85541

Recently, I decided to install a new radio in my vehicle, but didn't have any under-the-dash room (which you'll understand if you own a minivan like the Plymouth Voyager). There are, however, spaces between the front bucket seats, and between the seats and the dash, that are not used. Besides all that, I wanted a way to take the radio out of the vehicle and install it quickly; with only the antenna, power and ground connections to disconnect (or connect).

The requirements have been easily and inexpensively met by using a few lengths of PVC pipe, some Tee fittings, and some elbows. The design, which can be modified to suit your own needs, is one that I think you will adopt for your own installation. It took all of an hour to cut, fit, and glue the pieces together as shown. I used the 3/4-inch o.d. material, but you can use whatever is best for your requirements. The cost was well under $10 and, best of all, the standard mobile mount bracket that comes with a transceiver is easily and quickly attached to the PVC pylon. After all pieces are cut and fitted to satisfaction, each joint is cemented with PVC cement.

The length of the single support strut may be altered to meet the desired tilt-angle of the front parallel equipment support legs. The rectangular base can be designed with an appropriate size for your vehicle, and the length and width of the front support legs can be varied to suit...*before* you glue them together. To finish off my pylon, I bought a can of spray paint to match the plush interior color of my car (burgundy).

If you want or need a VSW8 bridge to go with your radio, there is plenty of spare room on this pylon for you to mount it. One of the MFJ-900 tuners is also mounted on my pylon with the radio, tuner, and VSW8 bridge, interconnected with short pieces of RG-58/U and appropriate connectors. Disconnect the ground, antenna, and power cords, and all the gear comes out with the mounting pylon. Try it. I think you'll like it.

You'll need: 6 90° elbows, 4 Tees, 1 48-inch length of 3/4 inch o.d. PVC pipe, small tube of PVC cement, and miscellaneous hardware as needed to attach the U-shaped metal radio mounting bracket to the pylon legs.

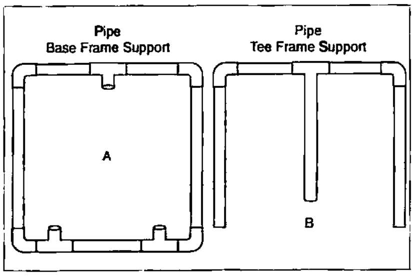

Fig. 1a. Pre-assembled frame: pipe base frame support.
Fig. 1b. Pre-assembled frame: pipe Tee frame support.

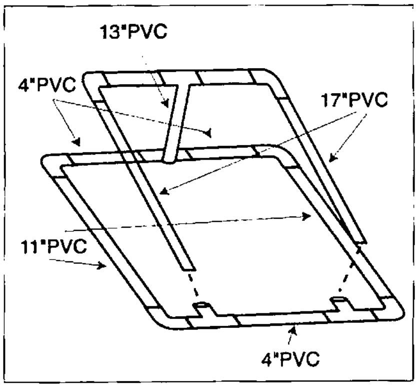

Fig. 2. Final assembled frame.

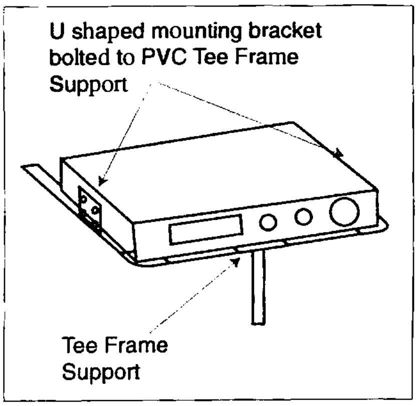

Fig. 3. Mounting radio to frame.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

Allow me a few lines to mark the passing of nineteen years of RTTY Loop. We've covered a lot of territory in two decades; from simple shift-pot FSK circuits, up through early ASCII, and now into a variety of computer modes and digital communication, this facet of amateur radio called RTTY spans a wide spectrum. It has been, and continues to be, my pleasure to bring it to you through this window I call "RTTY Loop."

Speaking of longevity, I have a note from Tom Watson WAØDJP, who professes following the column for years, being a Lifetime Subscriber to *73*. Those of you new to the magazine might ask, "Lifetime Subscriber? How much did *that* cost?"

Well, back in those days, depending on which deal you got, it cost either half of $73, that is, $36.50, or $37, that is, *73* reversed. The certificates read "Our life or yours." Don't we wish we could get that deal again!

Joe Ross AA5BD, writes: "I have been reading your column for quite a while now and enjoy it. Question: I have an old RTTY T.U. unit, made by IRL, their model 500. I was curious if you are familiar with it, and if you think the program Autort would work with it, or maybe you might suggest something else. I had the unit working many years ago on an old VIC-20—man, you should have seen those characters fly by on the screen!

"My good friend KG5CB and I worked the ARRL RTTY Round-Up a couple of weeks ago from my Dad's lake house in Jacksonville, a small town in East Texas. We used a Kenwood 450 with the Carolina Windom Antenna from Radio Works up about 50 feet in an East Texas pine tree. We had 320 contacts; we used a PK232 and had a lot of fun.

"I don't know if you are familiar with the news group RTTY List but it is fun, free, and I see some great comments and reports there. To subscribe just E-mail to:wf1b-RTTY-REQUEST@ve7tcp.ampr.org

"Put SUBSCRIBE in the subject line."

Thanks, Joe, for all the information. AUTORT, which is on the first disk of the RTTY Loop Software Collection, should work fine with a "plain vanilla" terminal unit like the IRL-500. I ran one of them several years ago, and it was a clean, solid performer. There are many other programs around, though, which will run with a plain terminal unit and computer. Take a look at the full list of what I have on the RTTY Loop Home Page, at http://www2.ari.net/ajr/rtty/ or send a self-addressed stamped envelope to the post office box above for a printed listing.

The setup for the RTTY Round-Up sounds like a winner, a basic no-frills rig that shows how easy it is to get out on digital modes. As to the news group list, I am passing it along to the readership. For those on the Internet, who don't want to get bogged down in reading one message at a time, subscribing to a news group like this can allow you to keep a finger on the digital pulse without having to go to the doctor (sorry about that!).

I received a note from Brian Vanderheyden, KBØPRY, which asked about a BASIC program for Morse code. As he wrote at the time:

"I saw in a back issue of *73* (May 1992) a BASIC program for playing random Morse code on a PC. I have a new toy...an Epson PX-8 laptop from '84, that uses CP-M and has BASIC on it. I wanted to try out the basic program that was written by Elwood Downey (WBØOEW) on the laptop (I also have a IBM-PC clone, which I am using now). Anyway, before I type all that code out, I was wondering if this file is available, say, here on AOL? I have been thinking about writing something I could use on the PX-8 and this looks like it might fit the bill."

So, I sent him a copy (digitally, of course) of the column, and he replied:

"Thanks for sending the BASIC program I asked for, along with the other two. I ran the random Morse program from my PC and it worked fine. I have ported it to the Epson portable. There are a few differences in the BASIC command syntaxes that have to be adjusted for. I got it to run up to the opening statement for selecting the source and for the lines for adjusting speed and tone, before I get an illegal function. Looks like I will have to compare some BASIC reference books and rewrite part of the code. The other two programs look interesting. I had to edit them to get them to run under QBASIC in DOS 5.0. The first program will run, and I am about halfway through the second one. Mostly putting spaces in the lines of code, and substituting some PRINT@ strings to just PRINT. I have wanted to learn how to write in BASIC (and Visual BASIC for Windows) so this little exercise will help me learn."

Sounds good, Brian. You might upgrade from DOS 5.0, though, at least to version 6.x, as there are a few new features that are worth it. I would be interested to see what you come up with, eventually. In the meantime, I will add the May 1992 column to the library of columns on the RTTY Loop Home Page, so that others can play with the code, as well.

Interest in the RTTY Loop Home Page, by the way, has been growing daily. I have received some comments that hot links to downloadable programs may not be correct. Please understand that when I link to the programs the link is correct, but that many of these programs are on other servers, producing what is often termed a "virtual library." If the other server changes the address, the link on my board will be wrong. If this happens, PLEASE let me know about it. I will either fix the link, or disconnect the link from the other server. I am also very interested to hear what you, my readers, would like to see on the page. I have tried to put up things asked for, such as the Morse program mentioned above. Drop me a line, and let me hear your thoughts.

Next month, as we begin the twentieth year of RTTY Loop, I plan to respond to many inquiries with some basic, very basic, looks at how radioteletype is encoded, transmitted, and decoded. For many of you, this may be a review; for some of you, this may be a revelation. I hope, though, that for all of you, it is interesting. In the meantime, visit the RTTY Loop Home Page at the address given above, or drop me E-mail at ajr@ari.net, MarcWA3AJR@aol.com, or 75036.2501@compuserve.com, or spend 32 cents and snail mail me at the post office box above. See you next month! 73

Number 87 on your Feedback card

Jim Gray W1XU
210 East Chateau Circle
Payson AZ 85541

June is expected to provide reasonable, but not excellent, conditions for DX on the HF bands, and might provide some interesting 6 and 2 meter propagation between the 10th and 12th. Sporadic E propagation could also appear on the higher HF bands, especially around days marked "G" on the calendar.

The best days should be June 2-5, 16-19, 26 and 27, and 30. The poorest days are likely to be June 9-13 and 2-23, and the rest are expected to be fair or trending, as shown on the accompanying calendar.

Remember that thunderstorm QRN and high signal absorption due to excess daytime ionization in the Northern Hemisphere are expected during the summer months, resulting in fewer DX opportunities on the HF bands.

10-12 meters

This is a daylight-only band this month, but may present openings to tropical areas as well as short-skip openings on the best days (G). During intense, sporadic E conditions (rare this month) bursts of strong signals can come and go unexpectedly. Stay alert.

15-17 meters

These bands could stay open into early evening hours with possibilities of trans-equatorial DX on good (G) days and evenings. Signals seem to peak toward the west during afternoon and evening hours. Short skip to 1,000 miles or so should be available on many days.

20 meters

This should be your main choice for DX-chasing. Because some areas of the world are dark and others are in daylight at the same time, you can expect dawn-to-dusk, and even later. DX opportunities on good (G) days/nights. Short-skip will prevail to about 2,000 during the day, and farther at night.

30-40 meters

You may find these bands quite noisy (QRN) during the daytime, due to the onset of thunderstorms this month, but will be quieter during the nighttime hours. DX to your east will be the best before midnight, and best to your west before dawn. Choose good (G) days for best chances of scoring a new country. Short-skip of 100-1,000 miles during the day, and 500-2,000 miles or so at night will prevail.

80 meters

You may find that 80 meters will provide DX on good (G) nights, limited by thunderstorm activity. It may also provide short-skip openings of 200 miles or so during the day and 2,000 miles or more after dark.

160 meters

There will be *no* daytime openings here, due to a high absorption of signals, but it ought to provide skip to 1,000 miles or so after dark. Only rarely will you find DX, and only on good (G) nights with low or no thunderstorm activity. Low-frequency static bursts, hundreds of miles in length, limit your spring and summer operations.

Let me know how these forecasts are working for you. W1XU

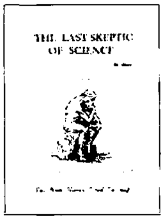
NASA Mooned America!

René, self-published, 176p, 1994 $25 plus s/h (available from Radio Bookshop). Theme of this book is that NASA never put a man on the moon; that the whole Apollo saga was just a Hollywood-like production done with the help of the CIA. My reaction on opening the book was that this is totally ridiculous. Crazy. Impossible. By the end of the first chapter I was starting to wonder if I'd sucked in on a $40 billion NASA production. By the end of the book I was convinced that, as impossible as it seems, the whole world has been suckered. If you read this book and find any fault with any of the 30 "gotcha's" I want to hear from you. For instance, the moon's surface has no moisture whatever. So why do we see boot prints where the astronauts have walked? You've walked in dry dirt and sand. It takes moisture to hold a print. When I start listing problems, every scientist I've talked to has ordered a copy of the book. Since this is not available from bookstores, and the author is understandably shy, I've arranged for Radio Bookshop to handle the book.



The Last Skeptic of Science

René, self-published, 179p, 1995, $25 plus s/h (available from Radio Bookshop). I was so impressed with the author's grasp of science that I had to get his other book. In this one René makes a very good case for Newton, Einstein, Hubble and a bunch of other scientific idols being in error. He makes a very good case for the moon not causing the tides, for the earth not being a magnet, for there never having been any ice ages, for light not having a fixed velocity, for different masses falling at different velocities in a vacuum, for there being no gravity waves...for gravity being an electrostatic attraction, and so on. The worst part is that he does a first rate job of proving his claims. You can drive scientist bonkers with this book. Worse, his arguments are in line with what I've read in the Lerner, Hoyle, and Hancock books I've recommended you read. They even are consistent with my own theories of gravity and inertia. *Wayne* 73

NEVER SAY DIE

Wayne Green W2NSD/1

ARRL Attacks FCC

Surely Wayne is exaggerating. Even the ARRL, which has pulled some corkers in the past, wouldn't be dumb enough to give the Big Kahuna a hot foot. Basically the League has the same complaint I've been expressing for many years: It's too bloody difficult to shut down hams who are causing trouble. There's a serious need for a shortcut to lifting the tickets of our more egregious offenders.

The result of all this is that the FCC has routinely been ignoring complaints from amateurs, no matter how well documented. And, of course, the bad guys know that they can get away with murder, even ignore fines, and nothing will happen.

So there's the League with a bunch of Official Observers who have zero clout. The League complained, "The League has had an Official Observer program in place, with dedicated volunteers, but its work product, once submitted, has been ignored and implicitly rejected by the Commission as a basis for any enforcement action, and the program is essentially non-functional as a result. The work of radio amateurs who volunteer thousands of hours monitoring these violations, conduct sophisticated direction-finding to identify the rule violators, and prepare transcripts for the FCC, has all gone for naught, and the volunteers are understandably and justifiably demoralized."

This lack of enforcement is well known and has contributed significantly to the growth of bad language, poor operating, creeping commercialism, malicious interference, and lawlessness on our bands.

The League is also on the FCC's case about interference to consumer electronic equipment such as TV, hi-fi, and so on. Consumers have every right to expect their TV sets to operate without getting interference from nearby transmitters. The manufacturers save a few pennies by leaving out the necessary filter. Oh, the FCC has told them tut tut, but it hasn't ever said dammit, put 'em in. The result is one heck of a mess, with consumers automatically blaming us for the interference. The FCC has the authority to fix the problem, but they've done nothing.

The question is, will the FCC see the error of its ways and reform? Or will it take aim at the messenger, shooting all of us down in the process? Well, that'll sure stop the complaints.

Yes, the League complaints are right. But I think they picked a really dumb way to tackle the problem. The FCC can be made to effect enormous changes if you go about it the right way. I was able to get the full cooperation of the FCC to make the biggest bunch of rule changes in history a little over 20 years ago, so I know it can be done, and how to do it. And it isn't by getting them mad at you.

Thanks K6YGK!

George Uminski K6YGK sent me a note with some stuff that might interest you. There was a column by Bob Pease from *Electronic Design* pointing out that people who use their minds a lot seem to be able to stave off memory loss and even Alzheimer's. Maybe I'm not completely wasting the time I spend compulsively doing crossword puzzles. He also passed along the address of Mead Killion, 61 Martin Lane, Elk Grove IL 60007, for anyone who thinks that hearing aids have to be lousy. He also included a review of *Reunions: Visionary Encounters with Departed Loved Ones*, by Dr. Raymond Moody. If I haven't reviewed this book for you yet, I should. I found it fascinating and convincing. It explains how anyone can set up a large mirror in a darkened room with only a 15W light and sit and talk with the "spirits" of those on the next astral plane. That's presuming there's anyone who's passed on that you'd like to talk with. Maybe 20m DX has more of an attraction than a parent or grandparent. I've been intending to find someplace around the house to set up a "psychomanteum" so I could thank whatever spirit keeps helping me at cribbage with "24" hands. And the angel who steps in to save me when people I've trusted take advantage of that trust.

More Ham Politics

When I got frantic calls from several of the repeater frequency coordinating groups asking if I would come to the ARRL-called coordinator's meeting in Missouri last October to help them deal with the ARRL, I begged off. I could see why the League called the meeting, but I didn't think that a fight on their turf, with them holding all the cards, was smart. Further, one of the League officials involved was a chap I'd trusted and then, I felt, had screwed me out of several thousand dollars a few years ago, so I thought that might interfere with my impartiality.

My advice to the coordinating groups attending the conference was to accept whatever benefits the ARRL was offering, but to form their own national coordinating council and cede no control. I suggested they look for a retired ham to run the council and cover his basic expenses with a small fee collected from each repeater they coordinate.

They were all adamant that they didn't want to turn coordination over to the ARRL, which was understandable.

I could understand, too, why the FCC would be enthusiastic about there being a Single Point of Contact (SPOC) for them to pass along repeater problems, thus saving them a ton of aggravation (and expense). I could also understand a certain reluctance of the ARRL, no matter their compulsive need to control every aspect of amateur radio so as to prevent any competing organizations from getting started, to put themselves into the position of being a deep-pockets target for lawsuits from every ham failing to get a coordination for his repeater. And we seem to be heading in the direction of there being one repeater for every licensed ham. Fine, we'll have 600,000 unused repeaters instead of a few hundred active and merely thousands of almost unused repeaters.

I probably shouldn't write about this at all, since every time I mention anything the ARRL is doing I get accused of being anti-ARRL. Go soak your head, if you think that. I'll be getting my 60-year plaque in a couple of years; how about you, buster? I joined in 1938. I would have joined a couple years earlier if W1CUN hadn't given me his 1936-37 *QST*s. Alas, when Cowan, the publisher of *CQ*, fired me as editor in 1960, he kept my 24-year collection of *QST*, my beloved SX-28A, my Navassa KC4AF DXpedition slides, and a bunch of other treasures. But since getting fired forced me to start *73*, that was a huge favor for me. That changed my life, making it possible for me to start *Byte*, *80 Micro*, *InCider*, etc.

I started building receivers and SWLing in 1936, graduating to bootlegging by 1937. Ask Walt WA6BMG about my early days on 160m in Brooklyn when he was W2LBF, just four short blocks from me.

Anyway, by forming a National Frequency Coordinating Council (NFCC), incorporating

Continued on page 7

LETTERS

From the Ham Shack

Bill Haddad WD9HXH. Talk about pissing contests! I'd like to do just that to many of your letter writers. What's this crap about agreeing with you 95% of the time, then proceeding to make feeble attempts at refuting your statements? Also, some of your readers (AB6QR is a good example) have a habit of misconstruing what they have read. They miss the point completely, then ridicule and display their ignorance attempting to disprove plain ordinary facts. I have reference to my letter in the August 1994 issue and a really dumb rebuttal in your November 1994 issue.

Bill included a column by Charlie Reese lauding the Duesberg book, Inventing the AIDS Virus,*for which, thanks. I caught the same column in* Conservative Chronicles, *which has some great columns by Thomas Sowell, Paul Harvey, etc. The Duesberg book seems in agreement with Dr. Douglass in his marvelous* Second Opinion *newsletter on the AIDS deal. Well, whatever the truth, the Beck gadget seems to be helping to solve the problem, as are the Dr. Comby and some other approaches, much to the consternation of the AMA, FDA, NIH, WHO, and AIDS activists, all of whom have a bunch to lose if a simple cure is found. Money talks ... Wayne*

Jim Hynde KA8DDZ. Sheeesh! I can't help wondering if we are ever going to stop worrying about our hobby falling apart. Why are some folks so hung up over our hobby remaining on the leading edge of technology, and promoting it to thousands of new hams each year? I got into this hobby because I was interested in shortwave radio and communications, not because someone sold me on the hobby. I enjoy it and recently joined the Northern California QRP club. What a great club! No meetings, no minutes, no one asking me if I am going to help with the parade or some other event. A radio club that makes kits for the members to build. Doers! I have had a ball showing my QRP rigs to friends and generating a lot of interest in the hobby, by the way. Meet another member on the air and you have got yourself a QSO!

No, I do not have to sell my hobby to anyone. They are either interested or not. If no one else ever wants to learn CW or pass an electronics test to get a license that's OK with me. If the hobby must die, let it die gracefully. I fail to see how you can artificially keep a hobby alive by stuffing it down the throats of our youth. In the March issue of *73*, a reader wrote "Dynamic young (-minded) people need to join the stagnant clubs and get involved." Ha! What on earth makes you think they would want to join such a club? Let's see now, how could we pitch it? "Hey there young high school kid, I want to introduce you to a club of old white cholesterol-laden ham radio operators who have been in the hobby for 30 years and don't want to do anything. Wanna join up?" You must be joking. If we're not attractive to the youth of today then think about how you can change your club to make it attractive! Don't ask our youth to join to add "new blood," make the hobby appealing and they will come. Wish I had a nickel for every enthusiastic kid who got into radio but was turned off by the incessant babble on 2m. Two options: learn to talk like the rest of the goons or be an outsider. It's disgusting.

I laugh every time I hear about a club doing a presentation at a school and getting no interest. I bet those kids are saying, "Gee, if this hobby is so great and wonderful why are these guys here trying to sell it to us?" I do it by showing the QRP rigs I've built and showing how much fun it is to send Morse code on a telegraph key. I get much more attention with that than trying to show the "high-tech" aspect of the hobby. Try and convince someone on the Internet who communicates in the "chat mode" with friends in Europe to get involved in packet radio, heh heh. Or show my friends who carry cell phones how neat a 2m phone patch is, har har.

So, enough about staying on the leading edge of technology. Why not just have some fun on the air? Build a radio! The new ideas and technologies will be born from the spirit of radio. I may be wrong, but I can't imagine that the forefathers of our hobby became hams because they wanted to develop a new mode called SSB or FM. I think they just wanted to have fun.

Fun is the key, of course. Repeaters are fun, at least at first. Some people have fun doing the same thing every day for years, others need new adventures to maintain their interest. We offer both. I'm a "been-there, done-that" kind of person, so I need adventure to keep my excitement going. Thus I keep getting involved with new technologies. For the unadventurous we have repeaters and 75m nets. But recruiting is important if we're going to hold billions of dollars worth of public property for our exclusive use. Congress isn't spending much of the taxpayers' money on maintaining horse trails. If we don't provide some sort of public service, we're goners, and all those wonderful excuses we had for the amateur "service" back 50 years ago have just about dried up and blown away. Like just about everything else, we're in a "grow or die" situation, so I suggest we sell QRP, DXing, satellites, packet, and so on. And sell hard ... Wayne

Paul W. Minor AAØXG. Sometimes it seems like all you get from the media is news about crime and evildoers. But there is a large group of people in this world who are quietly active in making the world a better place. These people become known only to the extent that they can do their function, otherwise they want to stay in the background, but let's resist that.

"Elmer" is an old term used in amateur radio to describe a person who helps new amateurs to get licensed and off to a good start in the hobby. We need to encourage and recognize these great people, so I propose we establish an "Elmer of the Year" award.

I have a candidate to propose for this award and hope that others will submit Elmers they have known so we can give them the recognition that they deserve.

My candidate is Ace Hudson AAØVM. He is a good example of what makes ham radio and the people in it fun. Ace is a real ham radio salesman. He talks to just about everybody he comes in contact with about it in barbershops, restaurants, stores—anyplace he can bring up the subject.

Ace has a regular parade of people coming to his house with old radios or questions about tests, antennas, etc., and they usually leave with study guides, handbooks, repaired equipment, and well fed. He keeps a library of study guides, code tapes and reference books to loan. Sadly, many of these loaners are not returned, so Ace replaces what he can with his limited income.

Ace is neurologically handicapped as a result of an auto accident and has a small disability income. Nevertheless, he has gotten his Extra Class license and is a volunteer examiner in charge of the local radio club's monthly exams.

Everybody in our club looks forward to Field Day, where Ace cooks a wonderful variety of gourmet foods for us. People like this enrich our hobby and make it what it is. Let's hear from others out there about their Elmers.

If someone will design a nice certificate, we can have an Elmer of the Month ... Wayne

Michael Farrar VE3WMF. You and many others complain that No-Code Techs do not "upgrade," but it is only upgrading in your terms. No-Code Techs see it differently. We see the CW requirement not as an upgrade, but as a backward step into yesterday with a bunch of old-timers who are forcing us to live with them in the past. You say that we can't win this by hassling the Techs. Ridicule won't work either. But you use the ultimate ham radio insult by referring to Techs as exCBers (most are not and those that are wanted to get out of that ugly

it, and then keeping it poor, potential lawsuits can be avoided. The NFCC would be valuable as a resort for those unhappy over some coordinating practices. While most groups are honest and fair, there are a few whose scrupulousness could stand some investigation. Some people just can't handle power honestly.

The main benefit to the ARRL of providing assistance would be an inside track on repeater frequencies for their *Repeater Directory,* which might help the publication be more accurate and up-to-date.

Adventure I

In my talks at educational and science conferences I stress the importance of amateur radio as a hobby entry into the high-tech world. I point out that ham radio offers plenty of adventure, as well as a sugar-coated learning experience.

When the Mohawk Amateur Radio Club newsletter published a list of famous radio amateurs (reprinted from *The Canadian Amateur*), naturally I couldn't help but go down the list and see how many I knew personally, or at least had met. And that got me to thinking about the adventure side of amateur radio, for it was through amateur radio that I got to know 20 of these famous hams.

Father Moran 9N1MM led the list. I first met him when I visited Nepal in 1966, where he put me up at his boys' school, and gave me a wonderful tour of the Katmandu area. We kept in touch after that. A few years ago, we met again in Singapore, and then again in Bangkok, where I gave a talk at the Seanet conference.

Next on the list was His Majesty King Hussein JY1, whom I visited and spent two weeks operating JY1 from the Royal Palace. Talk about an adventure! I had dinner with him and his family, and helped introduce amateur radio into Jordanian schools.

Then came Jean Shepherd K2ORS, the famous talk show humorist and later writer and film writer. Jean and I were good friends. I even taught him to water-ski on Jamaica Bay with my Chris Craft Express Cruiser.

I won't go down the whole list. That would expand this into another of my booklets. My trip around the world with Bill Leonard W2SKE could fill a hundred pages alone. My point is that all of these adventures came as a result of my interest in amateur radio, and I haven't done one single thing that any other ham couldn't have done. Or that any newcomer can't do.

It does mean my being adventurous rather than spending all my ham days making rubber-stamp contacts or checking in with the same small group every night for the rest of my life. Perhaps it's this same spirit that has triggered my entrepreneurial adventures.

My visit with Father Moran came about through my talking with Robbie 5Z4ERR in Nairobi many times on 20m. He talked me into coming over to visit. So I read a book on how to go on an African hunting safari for $690 by George Christian Herter and talked two other hams into going on the trip with me. Well, as long as I was going that far, I found that it didn't cost much more to keep on going around the world, so my safari stretched on to my visiting hams in around 23 more countries: Nepal, Burma, Ethiopia, Syria, Iraq, Iran (where I operated from the American Embassy), and so on.

Imagine the excitement of working your home station from Damascus (YK1AA), Nepal, Afghanistan (YA1NSD), and even on 75m from VK3ATN! Doing the kava ceremony with a village chief in a native hut on Fiji (VR2FD), zipping around American Samoa on a scooter, and flying all around New Caledonia with another ham in his plane.

Closer to home, I've had a ball mountaintopping on 2m from the highest mountains in Massachusetts, New Hampshire, and Vermont, working amazing distances from airplanes on 2m, and dawking a 10 GHz transceiver and dish to the top of Mt. Monadnock to work seven states on that band.

How about working moonbounce hams all around the world from the big dish at Arecibo?

If you haven't been having adventures in amateur radio, that's 100% your doing. Or, lack of doing. The adventure is there, just waiting for you. The opportunities are there at every turn, pounding away at the door. Take out your earplugs and have some fun that you'll never forget. I still talk about the 75m round table I tried to break into from Western Samoa (5W1AZ), but they said my signal wasn't strong enough so not to bother them. And my slow-scan operation from JY8AA and KC4DX (Navassa).

Have some adventure via amateur radio and then talk it up at your local schools. Get kids interested. Elmer. And I want to see some hint in the club newsletters that someone is making an effort to attract youngsters.

Also, newsletter editors, how about getting your fellow club members to write about their adventures in amateur radio? Thousands of hams have had wonderful adventures. Like when I went to Yugoslavia to help a fellow ham and his wife emigrate to America. Or when I "smuggled" hundreds of the latest transistors into Austria, Hungary, and some other European countries so the hams could build things. Or when I brought treasured American toilet paper to Bill Orr W6SAI, who was summering near Monaco on the Riviera.

There are plenty of fascinating and famous people to meet through the hobby, but you have to make an effort.

Now, what's the most exciting ham adventure you've had so far?

Adventure II

We have three main sales points when it comes to selling our hobby to youngsters. I do hope you aren't in disagreement with me about our needing to recruit youngsters. In the late 1940s and 1950s 80% of our new

DXer of the Year Nominations

The New Orleans International DX Convention is soliciting nominations for the DXer of the year award, to be presented at the 1996 convention Aug. 30-31. The recipient last year was Vince Thompson K5VT. All nominations received will be confidential and will be given equal treatment by the review committee. Send a letter describing your candidate and your reasons for the nomination to Michael Mayer W5ZPA, 5836 Marcia Ave., New Orleans LA 70124; FAX 504-524-2129. From *The DX Bulletin*.

FCC Commissioner Quello Issues Statement on Band Allocation

Introduction

1. By this action, the Commission addresses the Petition for Reconsideration (Petition) of the Report and Order in this proceeding filed by Fred Daniel d/b/a Orion Telecom (Orion). Specifically, we affirm our allocation of the 219-220 MHz band to the Amateur Radio Service on a secondary basis. We also maintain our regulations concerning the notification distance between Automated Maritime Telecommunications Systems (AMTS) and amateur radio operations, the exclusion distance between AMTS and amateur operations, and the type of equipment permitted in this band. However, we are amending our amateur rules to reflect the frequency upon which the AMTS stations operate. Finally, we are also taking this opportunity to update and correct the Table of Frequency Allocations as a purely ministerial matter.

Background

2. The 216-218 MHz and 219-220 MHz frequency bands are currently allocated on a primary basis to the Maritime Mobile Service for AMTS. In the Report and Order, we allocated the 219-220 MHz band on a secondary basis to the Amateur Radio Service for the provision of point-to-point fixed digital message forwarding systems, including intercity packet backbone networks. We found that this allocation will serve the public interest by: 1) relieving congestion that exists in the 222-225 MHz band in certain geographic areas; 2) encouraging the development and implementation of regional and/or nationwide digital message forwarding system networks that can be used for emergency and national defense communications purposes; 3) facilitating connection of local packet nodes to form such regional and nationwide networks; and 4) providing spectrum for exploration of new technology related to these purposes.

Submitted by Klaus Spies from PACKET.

Spread Spectrum Comment

The Tucson Amateur Packet Radio Corporation ("TAPR") submits the following reply comments regarding the Petition for Rulemaking (the "Petition") filed by the American Radio Relay League ("ARRL"), which proposed certain changes in the rules governing spread spectrum operation in the Amateur Radio Service ("ARS").

I. Permitting more widespread spread spectrum operation in the ARS would serve the public interest.

A number of the comments recognized the benefits that could be provided by more widespread use of spread spectrum technologies in the ARS. In addition to those that would accrue to ARS operators, as described in the Petition, increased use of spread spectrum in the ARS would contribute to the overall development of spread spectrum communications and, as a result, would provide benefits indirectly to commercial users as well.

Expanded use of spread spectrum in the ARS also would further the Commission's objective of promoting efficient spectrum use. At the FCC's March 5, 1996 *en banc* hearing on spectrum policy, Paul Barens, the "father" of one of the technologies that forms the basis of the Internet, made the following statement:

"What do we see today if we tune a spectrum analyzer or a radio receiver across most of the scarce spectrum bands? Mostly nothing. Dead air. This strongly suggests that most of our limited spectrum space is not being fully utilized and is going to waste. Specifically, with digital technology, spectrum bands can be more efficiently packed without interfering with existing services."

By increasing the ability of ARS operators to use spread spectrum technologies, the Commission would enhance their ability to use digital technologies to enhance spectrum efficiency, as recommended in the above passage. In turn, the Commission also would make it possible for the ARS to better accommodate the many new users seeking to use ARS bands, which are already congested due to the widespread use of non-digital equipment.

Although spread spectrum is not a panacea, it offers the promise of increased spectrum efficiency, reduced interference, and improved communication performance without adversely affecting other spectrum users. As a result, the Commission's rules governing spread spectrum operation should be modified to enable these technologies to flourish within the amateur service community.

II. Expanded spread spectrum operations will not adversely affect other ARS operations.

Several repeater coordinating organizations, who are responsible for the coordination of repeater operations in their regional areas of activity, filed comments opposing the Petition. These entities generally alleged that adoption of ARRL's proposals would cause widespread interference to, and disruption of, existing operations.

The fears and concerns expressed in these comments defy the proven ability of properly designed and implemented spread spectrum systems to operate in harmony with other spectrum users, are based upon "worst-case" scenarios, and reflect a desire to maintain the status quo even at the cost of stifling new technologies and services. As a result, they should not be permitted to prevent the development of spread spectrum in the ARS.

First, as discussed by Robert Buaas, claims that spread spectrum operation will raise the noise floor ignore the fact that few real systems operate near it, and those that do would profit from applying spread spectrum technology.

Second, in the ten years since the Commission first allowed limited spread spectrum operation in the ARS, a great deal of work has been done to address concerns that more flexible spread spectrum operation would adversely affect other types of ARS operations. In particular, the 1991 Buaas spread spectrum STA has made it possible for experimenters to engage in widespread use of spread spectrum technologies in the amateur band allocations below 450 MHz. Notably, operation under the existing spread spectrum rules and experim entation under the spread spectrum STA have not generated substantiated claims of objectionable interference.

Finally, the successful operation of Part 15 spread spectrum systems provide substantial evidence of the ability of these devices to coexist with other users. Today, millions of spread spectrum devices operating under Section 15.247 of the Commission's rules are being used to support end-user solutions in areas such as cordless phones, location monitoring devices, and local and metropolitan-area networking. These devices have been deployed across the United States without any local coordination and without any licensing by the Commission. Yet despite this flexibility and extensive use, spread spectrum Part 15 devices have almost universally operated without causing objectionable interference to other Part 15 devices or to others operating in shared spectrum. This success story provides ample proof that when spread spectrum devices are properly designed, manufactured, and deployed, they can coexist successfully with many diverse applications and, in addition, can facilitate frequency reuse.

In light of this history of successful, non-interfering operation, the Commission should not permit unsubstantiated claims of potential interference to thwart the introduction and use of new spread spectrum technologies in the ARS.

III. Section 97.119(B)(5) of the rules should be deleted, as suggested by NCS.

TAPR supports the suggestion made by the Manager of the National Communications System ("NCS") to delete Part 97.119 (b)(5), which

deals with the requirement for CW identification. TAPR agrees that no currently available commercial equipment implements such a function, and that deletion of this requirement will act to speed the rapid adoption of this equipment into use in the ARS.

Conclusion:

TAPR congratulates the ARRL for its forward-looking proposal to liberalize the spread spectrum rules in the ARS. ARRL's proposal, if adopted, could provide a variety of benefits to both members of the amateur service community and to the wider public.

Proposals to modify the status quo often generate opposition by those who are adequately served by it. Like the turmoil that occurred in the ARS during the transition from AM to SSB, the growing use of spread spectrum in the service will not be without incidents of disagreement and misunderstanding. For this reason, TAPR intends to use its resources during the rule making process to educate the ARS community on the theory, application, and practice of spread spectrum technology.

Yet, while fear and opposition are understandable, they should not be permitted to stifle new developments. In light of spread spectrum's strong track record and proven benefits, unsubstantiated claims of potential interference should be discounted and the Commission should act promptly to issue a Notice of Proposed Rulemaking proposing to implement the changes sought by ARRL, modified as discussed in TAPR's earlier comments.

TAPR believes that a program of continuing education of the ARS community on the merits and benefits of spread spectrum technology coupled with a wider use and deployment of equipment by amateurs in various applications, will go a long way towards resolving the concerns of many of those who have filed in opposition. TAPR intends to use its resources to perform this function and service for the amateur radio community in much the same fashion that it helped start the packet radio revolution in the ARS during the mid-1980s.

Respectfully submitted, the Tucson Amateur Packet Radio Corporation.

Touring and Tuning

From December 1995 to February 1996, my wife and I toured the southwestern United States. Our RV has a little 50-watt ham rig with a whip antenna on the rear bumper. During that trip, I tuned each of the HF bands at various times of the day to see just what activity was there.

I was amazed at how much was going on as I tuned from 160-10 meters. In almost every band and in almost every check there were more QSOs on CW than any other mode. The second highest usage was SSB, then various forms of digital communication, and last was AM voice. In that, the 10 meter band was most times dead. I did not hear any FM stations and only a very few 160 meters stations.

Who uses the HF bands? I found a good cross-section of ham radio. Daytime operation during weekdays was mostly older operators—mostly men of 60 and over. However, in this group, I found a number of lady hams operating CW, and a few on voice modes.

About sundown, the bands make a shift to the younger working people who now have a chance to enjoy our fine hobby. As we went into early nighttime, more and more younger operators filled the bands on all modes. Higher bands faded out many nights and the "good" bands became more active. The CW bands became very crowded at night.

On many weekends, the bands were filled with contest operators, with the CW bands being most active (CW takes the prize for the most activity per kHz of space during a contest while late nights and early morning are the prime time for the DXers).

What do hams talk about? Those of my age talk about health problems, economic stress among the elderly, children, grandchildren, radio in the old days, and conditions of community and government. Younger hams talk about computers, new radio gear, their antennas, and operating power. The youth of our ham community are not frequently heard on the HF bands except is for the Novice-Technician CW band.

I found message nets on many of the HF bands. The CW nets pass messages rather quickly. This appears to be the result of experienced operators and many coded messages. Voice messages often have reception problems, with phonetics slowing down the process.

DX pileups try the patience of most operators and lead to ugly remarks by a few, bringing shame to our hobby. This was the case on 75 meters, and to a lesser extent on 40 and 20 meters. Clean speech and courtesy are generally found throughout the CW bands, with few exceptions.

I did not have equipment to copy the digital signals. They were a small portion of the stations heard at any point in time. A very few digital stations were heard out of the generally accepted band plan. Likewise some CW stations were found outside of the band plan. However, in each case these things were not a serious problem.

What conclusion did I draw? Thousands of hams are busy expanding our hobby and our technology. Just a few darken our colors. Let's all work to enjoy, extend, and cleanse our wonderful hobby...de "Old Huck" Huckabee AA5BU. (Lifted from *AARC/Over-* Austin Amateur Radio Clubs Bulletin.)

Badger State Hams Pitch In

The north-central Wisconsin village of Weyauwega got an early and most unwelcome wake-up call on March 4, 1996 when, at about 5:45 AM, a Wisconsin Central Ltd. freight train en route to Neenah from Stevens Point derailed on the north edge of the village. Thirty-four cars left the tracks, 14 or 15 of which were pressurized tank cars filled with liquid propane. Six of those cars began burning.

Emergency officials decided to take no chances; all 1,700+ residents were evacuated

Ham Shack Test Equipment

What you really need, based on the author's 47 years of experience.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30, c/o Defendini
Salinas PR 00751-0030

Every ham shack, no matter how simple and inexpensive, or complex and costly, needs a certain amount of test equipment. Measurements must be made from time to time. Additionally, sometimes signals and voltages need to be generated.

The average ham does not have an unlimited budget, so he or she cannot load up on commercial test gear, most of which is rather expensive. However, some commercial test equipment along with some simple home brew gear, in the proper mix, will be cost effective and make every necessary job possible and easy to accomplish.

Digital multimeter

The digital multimeter (DMM) is probably the most-used item of test equipment in the shack. Although a few are available in kit form, they do not have all the usual capabilities of a full-featured DMM, nor are they very easy to construct unless you have lots of experience in close soldering on printed circuit boards. Therefore, I recommend purchasing a commercial meter.

Although prices range from about $20 to several hundred dollars, it is possible to purchase a full-function DMM for about $60-$80. By "full-function" I mean that the meter has the ability to measure (full-scale) AC and DC volts from 200 mV to 750 or 1,000 V, and AC and DC current from 20 mA to 10 or, preferably, 20 amperes. Resistance should cover 200 ohms to 20 megohms or more. The DMM should measure capacitance from 2 nF (0.002 µF) to 100 µF or more. Transistor DC beta (h_{FE}) should also be included. Most full-function DMMs measure from 0 to 1,000.

Some DMMs costing less than $100 will also measure frequency, usually to 20 kHz, and some as high as a few hundred kHz or even 1 or 2 MHz. However, they usually require a relatively high signal level, and with the usual 3 1/2-digit readout it is impossible to pinpoint a frequency higher than 9.999 kHz.

A few DMMs in the under-$100 price range will also measure inductance. However, the lowest range is usually about 2 mH full scale. Hams usually need to measure much smaller inductances in the µH range, so this capability will be of limited, if any, value to most, especially if this feature increases the price of the meter.

Almost all DMMs have a switch position for continuity, with an audible "beep" indication. Personally, I use the lowest ohms scale and glance at the readout.

All DMMs include a switch position to check diodes. Some work; some don't. Those that do work provide merely a go/no go indication. They will differentiate between open and short diodes, and functioning ones, but will not provide any indication of forward and reverse resistance, important characteristics of all diodes in many circuits. Attempting to measure diode resistances on the ohms ranges does not work. The voltage available at the test prods, usually less than 1 volt, is insufficient to bias the diode into conduction.

Analog multimeter (VOM)

A small pocket-sized analog multimeter which measures AC and DC volts, DC current, and ohms will be necessary when measuring forward and reverse resistance of diodes in order to match them. It will also be needed for monitoring voltage or current for a dip or a peak while adjusting other equipment, such as aligning or peaking tuned circuits in a receiver or transmitter, etc.

This type of meter does not have to have a high input impedance nor be particularly accurate-most such meters have an accuracy of only 2% or 3% of full scale. A multimeter with 1,000 or 2,000 ohms per volt sensitivity will be satisfactory. It will also be inexpensive. Buy one.

Dummy load

Although 50 ohm dummy loads for low power levels can be home-brewed using an appropriate number and values of 2 watt carbon composition or film (non-inductive) resistors (this is recommended if you operate only low power because it is cheap), many different manufacturers offer accurate non-inductive dummy loads capable of handling different power levels up to the legal maximum and higher. Prices vary from about $30 (MFJ-260B, 50 watts for three minutes, 300 watts for 30 seconds) to much more expensive load resistors mounted in gallon paint buckets full of oil. Choose one which will handle the power you are using, or plan to use once you get that amplifier you have your eye on.

Cross-needle SWR power meter

An accurate cross-needle SWR power meter rated for your output power or somewhat higher, connected between your rig and antenna tuner, will enable tuning for maximum power output simultaneous with lowest SWR. These meters are available from MFJ, Daiwa and other sources, in various power and frequency ratings. Some cover just HF through 30 MHz, while other HF meters include coverage of the 6 meter band. Others are available for VHF and UHF. Prices start at about $40 (MFJ-860, 30 and 300 watt ranges, 160 through 6 meters) and increase from there.

You can also home-brew SWR and power meters for HF, though you must use two separate meters, or switch a single meter between forward and reflected power. There are some excellent designs in W1FB's *Design Notebook* and other publications. Also check the back issues of the various ham magazines.

Garbage In—*No* Garbage Out

Turn hardware store purchases into a cavity filter for satellite and 2m reception.

John Portune AA6NG
724 Celestial Lane
Foster City CA 94404

Do you capture pictures from Automatic Picture Transmission (APT) weather satellites on 137 MHz? If so, you probably are plagued by aircraft interference. The APT satellite frequencies are uncomfortably close to the aviation band used by every airplane and airport in the world. I live right under the glide path of San Francisco International Airport and, to make matters worse, I run a high-gain receiver and a wideband GaAsFET preamp so that I can copy the satellites down near the horizon. I was a prime target for the endless flow of planes that passed over my house, resulting in innumerable glitched and noisy weather satellite images.

"I not only eliminated the interference from planes and the airport's tower, but I can now copy the WX satellites several degrees lower in the sky."

The bandpass cavity shown here was like pennies from heaven. Aircraft interference is gone, and I get noise-free pictures. But let me offer you some advice: Don't test the cavity like I did – in the middle of my home office where my computer and WX receiver are. The QRM from the XYL was far worse than that from the aircraft.

There is something fascinating about building an RF device from hardware store parts, especially a 20-gallon garbage can. Getting good results from such "garden" variety materials is very satisfying. By the way, you 2 meter types can effectively modify this cavity for use at 144-148 MHz by merely taking an inch off the center pipe.

Why you need a cavity

Many hams do not know that modern superhet receivers develop selectivity late in their circuitry. **Fig. 1** shows a simple block diagram of a typical modern receiver. The front end, including the RF amplifier, must be extremely broad. Its job is to span a broad range of frequencies. The 2 meter band, for example, is 4 MHz wide. The receiver's front end, by design, cannot exhibit high selectivity. Even receivers with helical resonator front ends are several MHz wide. Many of the commercially available receivers used by hams for the weather satellite band, like my Hamtronics R-138, are even broader.

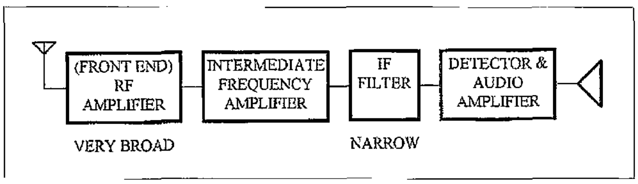

Fig. 1. Block diagram of a typical superheterodyne receiver. Selectivity is developed late in the circuit, in the IF filter. The earlier stages, especially the RF front end, are wide open to overload by strong adjacent signals and other noise.

A broad, unprotected front end like this can easily be overloaded (desensed) by signals several MHz off frequency. True, the IF filter in your receiver may stop you from hearing these signals, but such signals destroy the working sensitivity of your receiver whether you hear them or not. Even the normal noise in the passband of the front end of your receiver degrades the sensitivity. A receiver may show spectacular sensitivity when connected to a signal generator, but when it's connected to an antenna in a noisy environment, the working sensitivity of the receiver may be terrible. This is something many ham repeater owners often fail to consider.

By adding a passive filter ahead of your receiver and preamp, you will eliminate the aircraft interference the correct way and the effective sensitivity of your receiver will be greatly increased. I not only eliminated the interference from planes and the airport's tower, but I can now copy the WX satellites several degrees lower in the sky. Amazing, all of this from a garbage can, a piece of stovepipe, two connectors, and some 14 AWG wire!

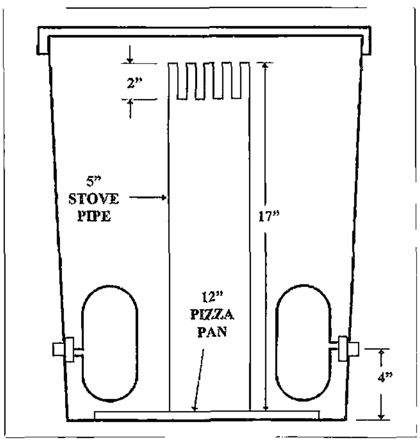

Fig. 2. Cross section of cavity, showing dimensions of inner conductor and placement of coupling loops.

Cavity basics

Like most of the cavities used in duplexers, this one is a 1/4-wavelength section of large diameter coaxial transmission line. It is open at one end and shorted at the other. The lid, as long as it is not too close to the open end, acts mostly as an RF-tight cover (see **Fig. 2**).

In designing any resonant cavity, theory specifies three things required for achieving efficiency: large volume, a 3.6:1 outer-to-inner conductor ratio, and low resistivity. Let's examine each briefly.

"There is something fascinating about building an RF device from hardware store parts, especially a 20-gallon garbage can."

Volume

Quite simply, the bigger the cavity, the better. Anything up to roughly 1/3 wavelength in diameter (21 inches at 137 MHz) will work. Above 1/3 wavelength, a cavity breaks into alternate modes of oscillation which have too much loss for filter service. Selectivity, the cavity's Q factor, improves in direct proportion to diameter. Since I was already constrained to make my cavity roughly 20 inches tall (1/4 wavelength on 137 MHz), when I visited my local hardware store in search of cylindrical metal containers with lids, metal garbage cans immediately caught my eye. They commonly come in two sizes: 20-gallon and 33-gallon. The smaller size is 17 inches in diameter and 22 inches tall. It was just what I needed, though the larger size would have worked well too.

Outer-to-inner ratio

A little-known fact about coaxial transmission line is that loss is minimum at a characteristic impedance of roughly 77 ohms. This is why we use 75-ohm cable where minimum signal loss is important, such as for TV receiver cables. We use 50-ohm cable for power applications because at 50 ohms impedance the cable will carry maximum power without breakdown.

The characteristic impedance of air line is determined mostly by the ratio of the diameter of the outer conductor to the inner conductor. For those of you who like mathematics, the formula for air-insulated coaxial line is:

$Z_0 = 138 \log(D_O/D_I)$

D_O = Diameter of outer conductor (the garbage can)

D_I = Diameter of inner conductor (both in the same units)

Since we want Z_0 to be 77Ω, we simply substitute in the above equation and find that D_O/D_I must equal 3.6.

In other words, the ratio between the garbage can diameter and the inner conductor needs to be 3.6:1 for low loss. Using a tape measure while still in the hardware store, I discovered that ordinary 5-inch galvanized sheet metal stove pipe is very close to the ideal size needed when used with a 17-inch diameter garbage can. Modest variations in this ratio are not critical, however.

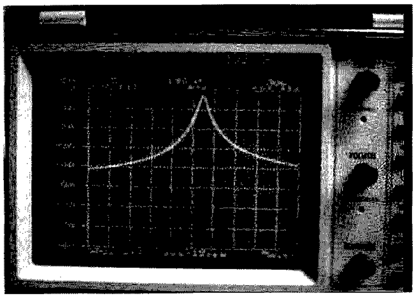

Photo A. Spectrum analyzer display of the filter's frequency response.

Low resistivity

The biggest source of loss in cavities is ohmic loss in the metal. It might not seem that something this large could have much resistance, but don't forget skin effect. RF current, even at low frequencies, flows in a thin film on the inner surface of a conductor, so even a large cavity can have significant ohmic losses. The galvanized surface of the garbage can is not a particularly good conductor. Aluminum or copper would be much better, but at this size and at 137 MHz the losses are modest. This is, after all, a receiving application where a few dBs are not critical. For transmitting purposes or duplexer use, you should go to the trouble of lining the inner surfaces of the cavity with copper or aluminum foil, particularly at the bottom and on the inner conductor.

The loops

Hams tend to consider cavity design a "black art," but it's not. Coupling loops seem especially mysterious, but are actually fairly straightforward. They simply need to be equal in size and shape, oriented perpendicular to the magnetic field, and placed near the shorted end of the cavity. The exact location, wire size and loop shape have very little effect on performance once they are optimized.

I simply kept changing the area of both loops, by altering the amount of wire or by bending the loops, until I obtained critical coupling. Critical coupling is the condition in which, as the loops get larger in area, losses have just begun to reach a minimum and selectivity is just beginning to fall off. This point is easy to find using a spectrum analyzer with a tracking signal generator (see **Photo A**). For this project, merely duplicate my dimensions and you'll be very close.

Construction

Dimensions and parts placement are shown in **Fig. 2**. Construct the center conductor by cutting a length of 5" stove pipe 18" in length (17" for 2 meters). At the bottom end, make axial cuts, 1" long and 1" apart, around the end to form bend tabs. Do the same at the top end, but make the tabs 2" long and 1/2" apart (see **Photo B**). At the bottom end, bend the tabs outward perpendicularly. At the top, break off every other tab, leaving the remaining ones straight. You will later bend these slightly to tune the cavity.

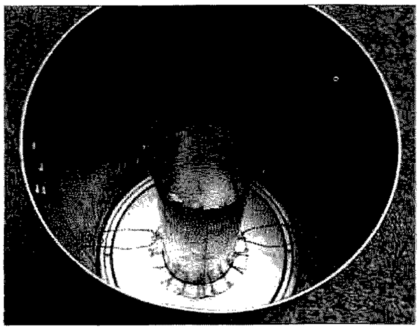

Photo B. Interior of completed filter showing center conductor soldered to pizza pan (in place) and coupling loops.

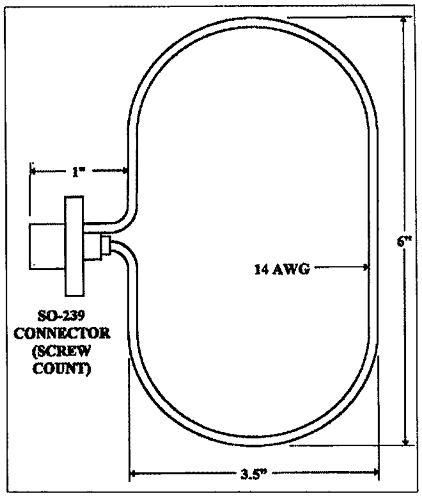

Fig. 3. Detail of coupling loops. Mount in the position shown.

Solder the bottom of the center conductor to the center of an inverted 12" common pizza pan (use a large, high wattage soldering iron). Use a pan that is not plastic-coated, or scrape off the plastic and tin the surface before soldering. Do not use excessive solder; it's required only for mechanical support. Capacity and skin effect make the necessary RF connection. Finally, secure the center conductor, on its pizza pan, into the bottom of the garbage can with a couple of screws.

Make the loops as shown in **Fig. 3** and **Photo C.** Attach the loop to its connector prior to installation. Install the connector and loop from the inside, rather than the outside. This makes the loops easier to remove. Use the kind of SO-239 connector that installs with four 4-40 screws, as opposed to the type that uses a large locking nut. Once the loops are installed, carefully bend the wire until both loops are the same shape and in the same position. The loops should be extended sideways so that they come within about 1/2" of the center conductor. Install them so that the end of the loop connected to the center pin is downward toward the bottom of the cavity. If you intend to install the cavity out of doors, be sure to seal the connectors from the weather. The lid need not be secured, but some wide plastic tape to hold it on would be a good idea.

Tuning the cavity

Be sure that the lid is on whenever you measure the resonant frequency. Without the lid, the resonant frequency will be quite a lot higher. The ideal test equipment to tune the filter is a spectrum analyzer with a tracking signal generator. With it you can display the shape of the bandpass curve, and set the coupling of the loops and the resonant frequency.

A less elegant way to tune the filter is with a dip oscillator. To do this, solder a small test loop of wire, roughly one inch in diameter, onto a PL-259 connector. Connect it to one connector on the cavity and connect a non-inductive 50-ohm terminating resistor on the other. You will then be able to "dip" the cavity at the small test loop.

Another possible method is to use an RF signal generator to inject a signal into one side and an oscilloscope on the other side of the cavity as a detector. Again, be sure that the cavity has a 50-ohm terminator installed on the output. The oscilloscope will have to be able to display a signal at 137 MHz.

If you lack the above equipment, you can also tune the cavity with just a signal generator and a receiver. Reduce the generator output until the received signal is near the quieting point of the receiver, and adjust the loops for best quieting. If you can't get your hands on a signal generator you can loosely couple some signal from a distant transmitter (yours or the satellite's) into the input of the cavity. Use a step attenuator

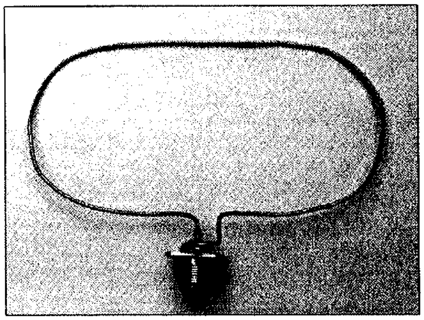

Photo C. Detail of a coupling loop.

on the output, and connect it to your receiver. Once again, adjust the attenuator to get the received signal down near the quieting point of the receiver, and make your adjustments.

Tuning is a simple matter. As you bend the tabs outward at the top end of the center conductor, the resonant frequency of the cavity will decrease. Effectively, you are adding capacitance. Such a cavity is electrically a parallel tuned circuit. Altering the capacitance in this way will not decrease the Q of the cavity to any degree. Q is determined almost entirely by cavity volume and metal resistivity. Tune the cavity for the center of the WX satellite band, or about 137.6 MHz. Changing the length of the inner conductor will also change the frequency. For 2 meters, for example, the center conductor will need to be roughly one inch shorter.

After building this cavity, I have to admit that it qualifies for an honored place in the long-standing ham practice of making do with very little. It also fits nicely into the grand ham tradition of tuna fish can, filing cabinet and lunch box radios. So if you are being plagued by pesky aviators or mountain-top intermod, give this project a try. You'll find it a winner, if you can get it by the XYL.

A Funny Thing Happened On The Way To The Shack

Strange stories from the world of hamdom!

Hal Goodman W3UWH
7 Perkins Road
Eastport ME 04631

Back in the days just after the FCC took 11 meters away from hams to create the Citizens Band, most of us still had equipment capable of operating on 11 meters. At that time I was living in a house on the top of a hill, an excellent location for transmitting. It seems there was this enterprising Citizens Band operator who would park his car right next to my house and spend several hours a day operating. There was nothing wrong with this, except he kept splattering all over my 10 meter receiver.

On several occasions I asked him politely to not park so close to my house, explaining that he was interfering with my 10 meter receiver. His response was that it was a free country and that this was a public street and I could investigate where the sun don't shine with my receiver. Well, I'm as patient as the next guy, but this was getting out of hand.

A little more information is necessary at this point in order to get the full import of what happened next. My equipment was Naval surplus out of an old battleship. You know the kind: solid silver coils, Faraday shields (also solid silver), etc., etc. It was built like the battleship it had come from, using the spare–no–expense government construction. When the Variac was cranked all the way up this baby could deliver a cool 5 kW without any strain.

And that's just what I did. I zero-beated his frequency, turned the Variac all the way up, pointed my three-element beam right at him and waited. As soon as he stopped talking and switched to receive I threw the switch and silently counted to five. Letting go of the switch, I walked to the window and looked out. What I saw was a large cloud of black smoke billowing out of his car. Some of you more technically inclined might be able to figure out just how many volts at what amperage I sent down his antenna. All I know is that it was enough. He never came back.

> ***"The priest, who was a ham, quickly realized that this was Morse code. The exorcism could best be performed by an electrician."***

There is a tale of a young ham back in the days when everybody operated AM. As the story goes, his neighbor, a middle–aged lady, filled her big old cast iron bath tub that had just had new copper pipes installed by her plumber. As she stepped into the tub, raising the water level just slightly, there suddenly came a voice speaking to her from the tub. Several Hail Marys later she once again she set foot into the tub and just as suddenly as before, a voice said unto her, "Five nine with QRM and a dipole."

Then there is this story about a lady who, on a dark, cold night, somewhere in the Midwest, dressed only in a robe and slippers, took the trash out. As you might expect, the door slammed closed behind her. She kept banging on the door and ringing the doorbell but it seems her husband, a ham operator, was in his shack with his earphones on, enjoying a DX with a ham Down Under, oblivious to all outside sounds. Finally, in desperation, she went next door and tried calling him on the phone. Same result. Luckily, the neighbor was also a ham operator, and was able to make contact with the station talking to the husband. Imagine his surprise when a voice with an Australian accent said, "I say, old chap, you'd better bloody well go down and let your wife in—it's bloody cold out there!"

Then there was the case of the haunted bedroom. It seems that several times a week, late at night, the lights in the upstairs spare bedroom would start to blink on and off, accompanied by a faint hissing sound. Thinking that there might be something wrong with the electrical system, the new home owner removed the fuse. When this didn't stop the light show, he called the previous owner for help. The previous owner told him that the blinking lights had been going on for as long as he could remember and that he didn't know what caused it either, but not to worry since it never hurt anybody.

Being somewhat less easygoing, the new owner decided to prevail on the local priest to come spend the night just to be certain the house was not haunted and in need of an exorcism. The priest, who was a ham, quickly realized that this was Morse code and recognized the call of a local ham. The next morning the priest explained that the exorcism could best be performed by an electrician—the length of the wiring in the bedroom was resonant on 20 meters.

Receiver Preamplifiers

The pros and cons of these little signal boosters.

Joseph J. Carr K4IP
P.O. Box 1099
Falls Church VA 22041

Preamplifiers and preselectors are popular antenna accessories, and are used ahead of receivers. If you use a separate receiver, or have one of those transceivers that permits a separate receive antenna, then you might be a candidate for a receiver preamplifier to improve performance. Chances are, however, that you're not such a good candidate. The preamplifier is one area where the actual performance is a bit counterintuitive. The "first blush" answer would seem to say that anything that boosts weak signals will help the reception of those signals, right? Nope! Not always.

"What do you mean, I've got mushy ghosts?"

The issue on receivers is the signal-to-noise ratio (SNR). If the signal level is above the noise level a certain amount, then you will receive it effortlessly. Some published sources say a signal must be 1 dB above the noise to be detected by ear, and 3 dB for reasonable copy by a skilled operator; effortless, comfortable copy is said to require about 10 dB SNR, which is how many rigs quote their own SNR.

The problem is that the preamplifier adds noise of its own, plus it amplifies the noise that's "out there" in the atmosphere. Thus, the preamplifier might impair performance, rather than boosting it. The correct solution is to buy a preamplifier that has a noise figure that's a lot better than the noise figure of the receiver front-end. A little bit of math called the Friis equation tells us that the major portion of the receiver's noise performance is set by the noise figure of the first amplifier in the chain. Thus, adding a noisy preamplifier ahead of a good receiver is dumb, but if the preamplifier is a lot better than the receiver, the overall performance is improved.

Maybe. There are other issues besides noise. You really don't want to have too much gain in a preamplifier ahead of a marginal receiver, or at all if the preamplifier is a little mushy. What does "mushy" mean? A proper preamplifier must have a high dynamic range, produce little intermodulation and have a high third order intercept specification. Otherwise, strong local signals in the same band with the desired weak signals may produce all manner of problems—like desensitization and ghost signals where none really exist.

Weather Control and Mind Control

Science fiction? Well, it's science but not fiction!

Jim Gray W1XU
210 E. Chateau Circle
Payson AZ 85541

This saga began with Nicola Tesla, was developed by the Soviet Union and the United States (Star Wars technology), and has been used on and off since the 1960s for both defense and offense. HAARP is being further developed for operation in Alaska at gigawatt levels. Look out, world!

HAARP stands for "High-frequency Active Auroral Research Project" and is a project that uses megawatts of VHF/UHF energy focused along Earth's magnetic field lines by multiple arrays of phased, circularly-polarized antennas. The purpose? To "heat" the plasma contained in the Earth's ionosphere and magnetosphere by adding energy in the form of atomic particles (electrons) which then produce patches, areas, and even "shells" of enhanced plasma extending around the Earth at the heights of the ionosphere and magnetosphere. These are designed to:

- Disrupt radio communication.
- Disrupt electronic navigation and guidance systems.
- Destroy satellites, directly or indirectly.
- Destroy ICBM missiles and/or warheads.
- Control the weather.
- Provide a new means of communication.

This new technology creates extremely high-energy particles which can be guided along magnetic field lines to locations at various selected altitudes above the Earth. These areas of super-high energy can be made self-sustaining for specified periods of time, meaning that their effects upon the Earth (and us) can be designed and maintained at will...and within a few minutes of turning on the generators.

"Great areas of Earth can literally be 'frozen' or 'fried' at will by controlling the movement of air masses, particularly near the poles, where most of the Earth's weather originates in the form of high- or low-pressure air masses."

Frequencies and energy levels can be chosen to deplete specific areas of the atmosphere of nitrogen, oxygen, carbon dioxide, and other gases...or, conversely, enrich or enhance other areas with the same gases. Great areas of Earth can literally be "frozen" or "fried" at will by controlling the movement of air masses, particularly near the poles, where most of the Earth's weather originates in the form of high- or low-pressure air masses. These can be "artificially" moved and their pressure changed.

What about the "Woodpecker"? It was a Soviet system consisting of three plasma heaters: giant megawatt transmitters which were *not* over-the-horizon radar, as claimed by our government, although they could be used for that purpose. The main purpose, however, was for weather and mind control...yes, *mind* control.

The complex waveforms were generated, focused, and directionally guided by three Siberia-based transmitters to any point on Earth in a manner similar, but in reverse, to the way receiving antennas can locate the source of a received signal by triangulation. The transmitted signals are thus combined at the selected point by radio interferometry to produce various concentrated effects.

The frequency-agile Woodpecker signals were transmitted in the HF bands and exhibited waveforms containing unusual pulse and pulse combinations between about 10 and 20 Hz. Ten Hz pulses resonate at the approximate frequency of the space between the surface of the Earth and the ionosphere, producing what is known as Schumann resonance.

The human brain produces electrical waves whose frequencies are between about 0.5 and 25 Hz, and can be affected by concentrated pulse energy at these frequencies. These so-called Alpha, Beta, Delta, and Theta frequencies are each related to various "states" of consciousness. Therefore, interference with any or all of these frequencies by external means can effectively change human behavior.

Note 1. Alpha frequencies are about 7-13 Hz, Beta about 13-25 Hz, Delta about 0.5-3.5 Hz, and Theta about 3.5-7 Hz. The Alpha state is a relaxed and receptive state of consciousness where a question put to an individual in it may produce a response in the form of a

Theta burst in the Alpha wave known as the "K" or potassium spike.

Just suppose the Woodpecker actually interfered with brain waves in a single individual or a mass of individuals. energetic particles to "supercharge" the ionosphere and magnetosphere. In fact, Tesla predicted that someday artificial auroras would be produced to flood the world's cities with a soft illumination after dark. How else than by plasma stimulation and enhancement?

"Are there any radio amateurs out there who listened (one couldn't avoid it) to the Soviet 'Woodpecker' and experienced changed states of consciousness or aberrant behavior?"

What were the consequences? Are there any radio amateurs out there who listened (one couldn't avoid it) to the Woodpecker and experienced changed states of consciousness or aberrant behavior?

The required power level for effective alteration of plasma to create such effects is in the gigawatt range, but produceable by magneto-hydrodynamic devices using power fueled by natural gas, oil, or coal deposits and/or hydroelectric generators.

Alaska's natural resources of gas, coal, and oil are ideally suited for production of power of the magnitude required for plasma-heating transmitters. Of particular interest is the fact that great sources of natural gas and oil on Alaska's north slope are ideally located where polar magnetic field lines are concentrated. You may correctly assume the HAARP transmitters are located there.

The Earth can be considered somewhat like a bar magnet in which magnetic field lines originate at the ends and diverge at the center. Most of us remember science classes in which the teacher laid a paper or card on top of the magnet and sprinkled iron filings on the paper to make the field lines visible. The Earth's magnetic field lines of force originate at the poles and diverge over the equator. Launching electrons along these field lines is a simple exercise in electrotechnology.

Nicola Tesla developed his "magnifying transmitter" based on the Tesla coil and resonance effects to generate power (not just "signals") and transmit it wirelessly over substantial distances. He succeeded in doing so in Colorado before the turn of the 20th century. Tesla coil research and practice has been carried on ever since by numerous companies and countries. The military interest is, of course, power and control. "Magnifying" transmitters based on the Tesla principle are capable of producing

In the late 1950s and early 1960s, atomic and hydrogen bombs (euphemistically called "devices" by the military) were detonated in the ionosphere and magnetosphere to supply vast excesses of high-energy particles and create a radio "blackout" and disrupt radio communication. It worked! I happened to be on the air during one such test in 1958, and totally lost receiver signals for over an hour...on all bands. Everything "went dead" and I thought my receiver had died. Not so, as I later discovered when I talked to many hams who suffered a similar mysterious signal blackout at the same time. It was only years later that the truth was made public.

Satellites were also used to "seed" the ionosphere with radioactive particles and thereby enhance the plasma by alternate means. Another experiment sowed millions of tiny copper needles around the earth at an altitude of several hundred miles. It worked...but only marginally...as signals were temporarily intensified (not blacked out), but soon lapsed back to normal. Not everyone was enthralled with the idea of an artificial shell of copper encircling the earth.

HAARP transmitters ordinarily employ electrons whose masses are more easily raised to the point of cyclotron resonance, but particles of greater mass can be accelerated to produce "beams" of heavy-element ions, for example...and these can do great damage to distant objects (targets). We used to call them "atom smashers" in the old days, but technology has advanced as far beyond that simple phrase as electricity has advanced beyond fire.

Given the ability to raise the energy levels of plasma electrons and ions to sufficiently high levels, dispersion becomes a problem. That is, for maximum concentration of energy on a small area,

Given the ability to raise the energy levels of plasma electrons and ions to sufficiently high levels, dispersion becomes a problem. That is, for maximum concentration of energy on a small area, the particle "beam" must be very narrow. Lasers maintain collimation and in-step light waves more easily than devices that use heavier particles.

Ions of "heavy" elements (elements having greater atomic weight) are focused magnetically by cryogenically-cooled toroidal electromagnets placed along the beam path. A similar principle is used in your TV set, which deflects ions away from the electron beam and "traps" them to avoid destroying the screen of its cathode ray tube. A device that "shoots" and focuses electrons is called an electron gun, and a device that "shoots" ions is therefore an ion gun. The greater the atomic weight of a chosen "ammunition" element, the greater the power of the ion gun must be for particle acceleration, containment, and focus.

The Eastland patents

There are three basic patents relating to the production, use, and effects of enhanced plasma: U.S. Patent 4,686,605, issued August 11, 1987, to Bernard J. Eastland of Spring, Texas, and assigned to APTI, Inc. of Los Angeles, California, titled "Method and Apparatus for Altering a Region in the Earth's Atmosphere, Ionosphere, and/or Magnetosphere"; U.S. Patent 4,712,155, issued December 8, 1987, to the same inventor and to Simon Ramo, Beverly Hills, California, assigned to the same assignee, titled "Method and Apparatus for Creating an Artificial Electron Cyclotron Heating Region of Plasma"; and U.S. Patent 5,038,664, issued August 13, 1991, to (not available to this author), assigned to (also not available to this author), titled "Method for Producing a Shell of Relativistic Particles at an Altitude Above the Earth's Surface."

There are alleged to be at least 12 more related patents issued to Eastland et al. which describe in detail the "Treator," "MHD Generator," "Transmitter," and "Antennae," plus a wealth of ancillary devices, methods and uses. As in the three basic patents, all of the information contained in the earlier patents is incorporated in the later patents by reference.

Note 2. The following references are of particular interest: "Ionospheric Modification Theory," G. Maltz and F.W. Perkins; "The Platteville High Power Facility," Carrol et al.; "Arecibo Heating Experiments," W.E. Gordon and H.E. Carlson, Jr.; "Ionospheric Heating by Powerful Radio Waves," *Radio Science,* Vol. 9, No. 11, November 1974, pages 885-888, 889-894, 1041-1047, and 1049-1063, respectively. "The MST Radar at Poker Flat, Alaska," *Radio Science,* Vol. 15, No. 2, March-April 1980, pages 213-223. *Controlled Thermonuclear Reactions,* Glasstone and Lovberg, D. Van Nostrand Co., Inc., Princeton, NJ, 1960. *The Radiation Belt and Magnetosphere,* Hess, Blaisdell Publishing Company, 1968.

Note 3. Frequencies used by HAARP are 1.45 MHz, 1.8 MHz, and 7-20 MHz. "A Theoretical Study of Electron-Cyclotron Absorption in Elmo Bumpy Torus," Batchelor and Goldfinger, *Nuclear Fusion,* Vol. 20, No. 4 (1980), pages 403-418, describes one type of controlled nuclear fusion device in which heating is provided by microwaves at the electron-cyclotron resonance interaction.

Further information about HAARP and other fascinating subjects which may be of critical importance to our future may be obtained from the International Tesla Society, Inc., P.O. Box 5636, Colorado Springs, CO 80931; telephone (719) 475-0918; or FAX (719) 475-0582. Ask for their catalog of handbooks, guides, manuals, and summaries.

Much of the information for this article was taken from the *1995 HAARP Resource Guide,* available as #290004, and priced at $19.95 plus shipping and handling.

[A note from El Supremo: Can our beloved government really be planning to experiment on us on such a large scale? You can order Nick Begich's book, Angels Don't Play This Haarp, *from the Tesla Society book store (233p., ISBN 0-9648812-0-9, $15, 1995) and get the straight dope. More and more Alaskans are learning about this massive government project and there's a move in the Alaskan legislature to stop this nonsense before it gets operational. Well, exposés have shown us that they've done this sort of thing before with radiation and many drug tests on unsuspecting people. Meanwhile, the construction of this secret multi-billion dollar project is moving ahead in Alaska, with the whole world as guinea pigs... Wayne]*

A Funny Thing Happened On

Continued from page 16

And then there was the time I was "reading the mail," listening to a local station talking to KC4USN, the Naval Antarctic station. In the middle of his transmission he suddenly said, "Stand by, must QRT for a minute." When he came back on he apologized for the interruption, explaining that someone must have left a door ajar and he'd had to shoo out a penguin that had wandered into the shack. Life is too short for QRP (QRPenguin, that is).

These are just a few of the funny and unusual incidents involving ham radio that I have accumulated over the years. I'd be interested in hearing about other incidents you may have experienced or heard about. 73 Hal.

Receiver Preamplifiers

Continued from page 17

The ghost signals problem was driven home to me by a fellow who proudly boasted that he had two, count 'em—two, 20 dB preamplifiers ahead of his 2-meter band receiver. Oddly, he thought, there's a problem with the receiver because other hams' signals appear at two or three spots on the dial. No kidding. That receiver was experiencing front-end overload, and it's not necessarily clear whether the overload was in the receiver itself or one of the those preamplifiers. Disconnecting one of the preamplifiers gave him plenty of weak signal performance, but reduced the overload problem to negligible levels. Too much of a good thing isn't a good thing.

At the end of the day, if you want to improve your receiver's weak signal performance, put the first dollars into the antenna system (besides, it helps on transmitting as well). A good beam antenna is not too awfully costly at VHF/UHF frequencies, and some other forms (e.g. vertical collinear array) are positively cheap.

One thing that many people don't realize is that a lot of the wire array antennas found in textbooks (like my own *Practical Antenna Handbook* or *Receiving Antenna Handbook*—see Radio Bookshop) are practical at VHF/UHF even when they take too much space at HF frequencies.

Persistence Wins

Nothing ventured, etc.

King Waters KK5LU
4003 Grennoch
Houston TX 77025-2301

I took my test for Advanced the other day. It was a step far removed from my mind that day two years ago when I sat for Novice.

All this wasn't really my fault. I have wanted to be a ham since I was 11; radio fascinates me. I am told that at the age of three I disassembled an old black Philco AM broadcast receiver, while it was still plugged in. I must have done a good job; the repairman said he couldn't fix it.

But that was the tenor of my radio experience—fascination, interest, destruction. I learned Morse code as a Boy Scout, but radio theory was never a strong point. One of my best friends understood it backwards, but his interest was hi-fi, not ham.

"I was stunned. They had to tell me twice."

I would read up on the hobby occasionally. I bought ARRL books from Radio Shack™ right after I got married in 1972, but they were written by engineers, and I was a journalist. I still have the books. There are ads in the back for crystal-controlled ICOM 2 meter mobile rigs, and Heath kits, but my attention wandered.

Law school, a litigation practice, and four sons intervened. Then two things happened independently: I accidentally bought a copy of *73*, and I copied some CW. That's what started me off to that VE session the other day.

In 1992, I had a case involving a fatal accident on a microwave tower. The case centered on a claim of defective climbing belts. At a bookstore one day I saw a copy of *73*, and thought it might have some information on safety around towers. It did, although that's another story, but the important thing for me was that it also said there were study courses for licensing now, and that testing was by VEs, not the FCC. I thought I might look into it when I had the time.

Then I went flying that summer with a friend. We were navigating from Mobile to New Orleans when he asked me to tune in a directional beacon. The beacon would have a Morse identifier, he said, so the dots and dashes were printed on the air chart. I tuned to the frequency, but I recognized the code without the chart. He was surprised. So was I.

I went to Radio Shack and bought the Novice course. The code work went

JPS Communications NIR-12

DSP? Yes, you need it!

Pete Ferrand WB2QLL
65 Atherton Avenue
Nashua NH 03060-1904

The endless struggle to hear signals with a minimum of noise has given rise to many little boxes with knobs over the years. However, I believe the best solution to date is digital signal processing (DSP). Let's face it, a computer can analyze a signal a lot better than a pair of diodes clipped across a speaker line. If that means nothing to you, it might be fun to take a nostalgic trip through the magazines and handbooks of 30 or more years ago to see just what our now old-timers were up against.

"Now you can have a 50 Hz bandwidth if you want it."

About five years ago I asked *73* if I could do a review of the JPS NIR-10. After using professional noise reduction gear, I was eager to see what a more reasonably priced ham version could do. The result was not only a positive review, but a unit that got used almost every day until last month, when I upgraded to the new NIR-12. The bottom line is that I'm now using the NIR-12 every day. This clever device gives me an array of weapons to fight interference in just about all modes: voice, CW, the digital modes, and TV.

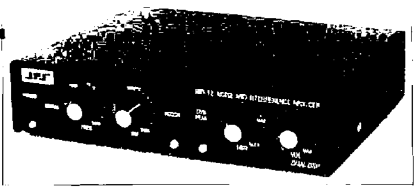

***Photo A.** The NIR-12 noise and interference reducer.*

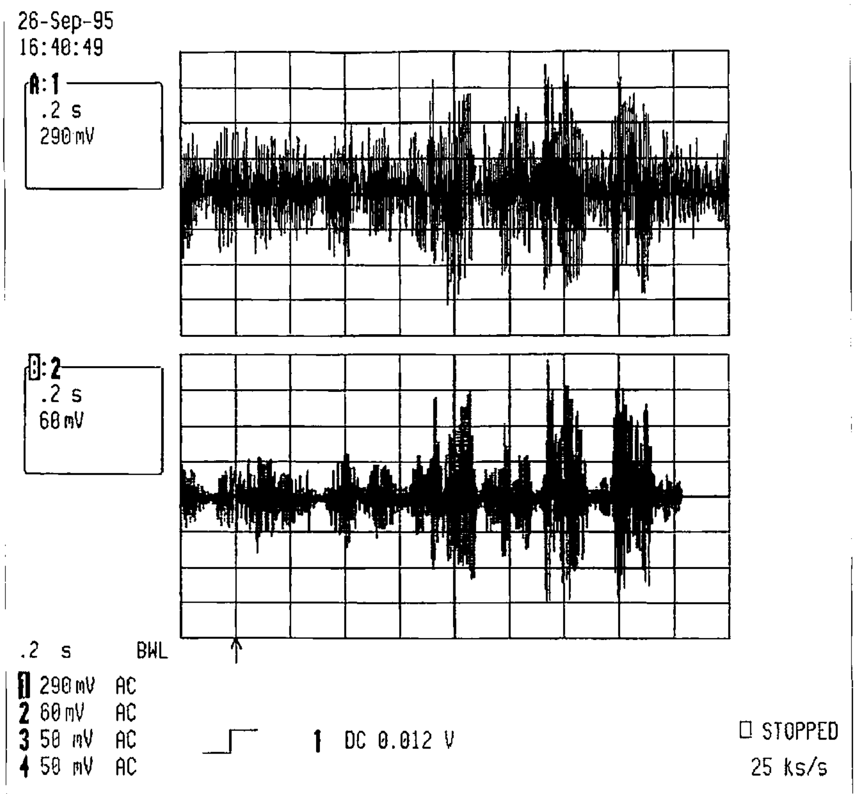

***Fig. 1.** The upper trace shows the unprocessed audio of a phone station in the noise. The lower trace shows the effect of the NIR-12, NIR mode only, NIR control set to 10 o'clock. The pattern displays amplitude on the vertical axis, time on the horizontal. The timing has been adjusting to compensate for the NIR-12's delay.*

Noise reduction systems

A DSP unit first digitizes the signal in a way similar to the process used to create sound from a computer or audio compact disc. The unit then analyzes the signal, tries to find what it's looking for, and subtracts the remainder. To the degree that the noise doesn't sound like what you're looking for, the NIR-12 can reduce it.

Any noise reduction device works best with a strong signal and little noise. Big deal, right? One good way to reduce receiver noise is to turn down the RF gain control, with either a knob or a front-end attenuator. I like to demonstrate this to any newcomers who, for some reason, have never learned to use those controls on a rig. As long as there is a reasonable difference between the signal level and the noise level this method is very effective.

The difference in noise reduction systems is most evident when there's about zero difference, or 0 dB, between the noise and the signal. It's also much harder for electronics (or our ears) to figure out the difference between noise and signal with something as complex as the relatively wideband human voice. It can do much better with a data mode, which is narrowband and usually synchronous (PACTOR, Clover, etc.), where the demodulator knows when to expect the signal and what it looks like, and can ignore what's left.

While we're waiting for some mode that digitizes our voices, we'll have to contend with pulling voices through an array of noise and interference. It's just getting worse with more electronics in our midst.

I work as a radio talk show host, and one of my major radio pursuits is listening to my competitors on other stations to make sure I'm being consistently original (yeah, right...). Living in a city and trying to listen to AM stations is about the toughest challenge for noise reduction.

The NIR-12 does the best job of any similar unit I've seen. It's also better in every respect than the previous JPS unit, the NIR-10.

One question that arises is why anyone would buy a DSP accessory when many transceivers now have them built in. The argument for the built-in unit is convenience and simplicity. Buying something like the JPS means you have the flexibility of using DSP with a variety of radios, especially mobile ones, or you can even clean up a noisy cassette tape. Then, when the technology is improved, you can get a newer DSP unit without having to upgrade your transceiver.

The NIR-12's features

Now, let's take a look at the NIR-12. It's built in a heavy steel box which provides magnetic shielding and keeps it from moving around when operated. The hookup is simple – you feed audio from the speaker output into the NIR-12's input, and connect the speaker to the NIR-12's output. It needs 11 to 16 volts DC, which you can get from the rig or wall transformer. Then all you do is adjust the receiver's volume control until the "signal" LED flashes on signal peaks, and control the speaker audio to your liking with the NIR-12's volume control.

You have four modes of operation, plus a pass-through mode where no noise reduction is performed. The modes are: NIR mode for spectral noise subtraction, dynamic peaking mode, bandwidth control, and a notch filter.

"The NIR–12 works well, and JPS's reliability and customer support are superb."

NIR mode

The NIR mode (for Noise and Interference Reducer) tries to recognize human speech and pass it, while reducing everything else. Most CW and data modes sound close enough to speech to pass as well. By adjusting the front panel NIR control, you can change the amount of noise reduction. This is the mode that works best on general electrical noise, static, and auto electrical system interference.

Five years ago I thought it would be helpful to put the noise reduction to a test, so I asked my friend John Seney WD1V, the area sales engineer for LeCroy, to come by with one of his fancy digital scopes to get a printout of what the difference is with and without the unit.

Well, now it's 1996, John's still my friend, and he's still selling for LeCroy, so once again he stopped by and took some scope printouts of 40 meters in the

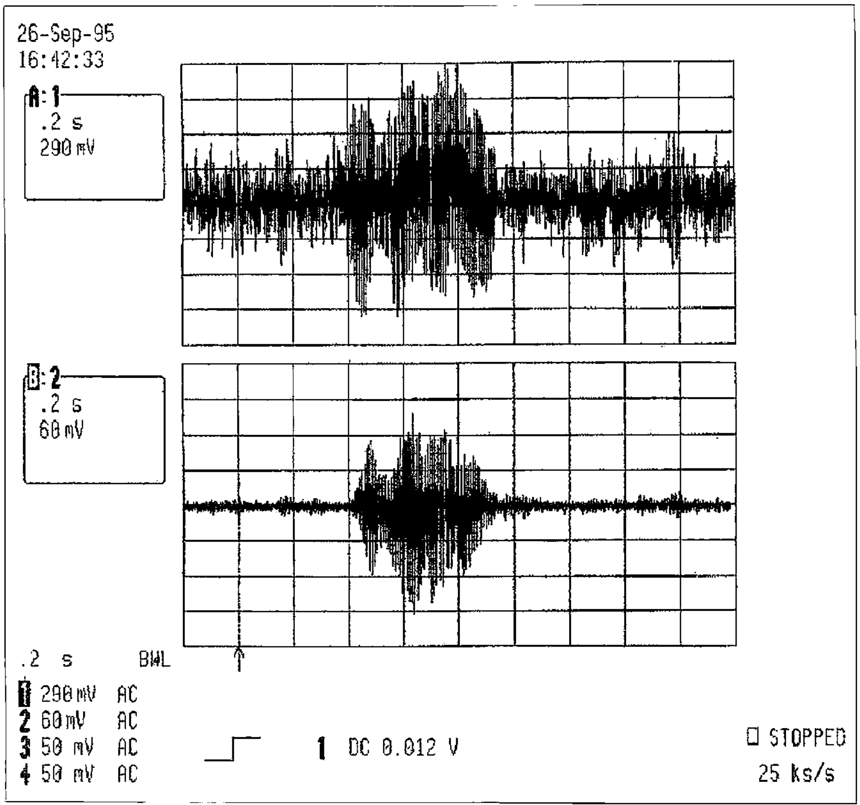

Fig. 2. The top trace shows unprocessed audio; the bottom one shows dynamic peaking mode. The data for the traces in both figures was captured at a sample rate of 25,000 samples per second. Each trace is two seconds long, so you're looking at 50,000 samples for each trace.

afternoon. I was using the same receiver, but yes, it's a much better scope!

The NIR mode graphs are shown in **Fig. 1**; the difference between the top and bottom traces is quite evident. I adjusted the NIR level for what sounded best to me, not the highest noise reduction, which JPS specifies as 0 dB.

The NIR-12 has an automatic mode that engages when the control is turned fully clockwise and provides a setting based on signal-to-noise ratio, and for some types of noise it's pretty close to optimum.

The problem with this subtractive type of noise elimination is that de-randomizing the noise leaves odd artifacts in the remaining signal. It seems much improved over the NIR-10, probably through an improved algorithm, or perhaps I've just become used to it. After all, I must have been used to listening to plain old radio noise, though I really can't remember that far back.

Dynamic peaking mode

The dynamic peaking mode looks for coherent information in the received audio, be it voice, CW, or data. It then forms a peaking filter around the coherent information. By "peaking" we're talking about a filter passing a bandwidth that's only as wide as the coherent signal. This mode is activated with a front panel push-button, and its aggressiveness is controlled with a three-position slide switch on the rear panel.

Dynamic peaking works best on general atmospheric noises. You lose just about all naturalness of voice, but sometimes it lets you copy an otherwise impossible signal. I'd have preferred that this mode be less aggressive. A knob for continuous control might have worked better than the three-position switch. Interfering voice signals are just as coherent as the one you want, so, by itself, dynamic peaking doesn't help, but you can use the bandpass controls to reduce nearby signals and the two work well together.

The artifact that dynamic peaking produces is, in JPS's terms, a "surging" quality which is hard to describe. I've discovered that by using an audio equalizer between the NIR-12 and the radio I'm able to improve the voice quality. A boost in the speech range of the voice being listened to can sometimes make the sound more palatable.

You won't see the artifacts, but you'll see the dramatic noise removal between the top and bottom traces in **Fig. 2**. As before, this is 40 meters at mid-afternoon.

Notch filter

The notch filter is much simpler to understand. It hears a tone and, if the "Notch" button is depressed, in five milliseconds 50 dB of the tone is eliminated. It will attenuate a whole bunch of tones, although there's less attenuation for more than four of them.

The notch mode is useful in getting rid of heterodynes, some data transmissions, noise from a nearby computer, and even people whistling to tune up. It isn't useful on CW or data modes, since it interprets those as tones as well. It's very impressive to visitors when they press a button and the tones just go away. This feature is very good about not removing any more of the audio than is necessary.

Bandwidth control

The audio bandpass filter provides a continuously variable passband of 50 to 3400 Hz. The center frequency of the filter can be varied from 200 to 3400 Hz. If you think for a moment, you'll see that this amounts to a low-pass filter with the center frequency at 200 Hz, and a high-pass filter if you set the center frequency at 3400 Hz.

As is typical of digital filters, the "skirts" are extremely steep; that refers to the graphical representation of bandwidth along a horizontal axis and amplitude along the vertical. It basically means that anything outside the bandwidth you have set is attenuated by more than 60 dB.

The most obvious use is with a receiver that has low quality filters, such as inexpensive shortwave portables. The other use is for modes that you don't have crystal filters for. Now you can have a 50 Hz bandwidth if you want it.

Most operators aren't aware that you can understand a voice signal with only a 1000 Hz bandwidth. That's because you can adjust the center frequency to anything you want, so you may find you

Persistence Wins

Continued from page 21

easily. My trouble was, and remains, theory. When I got to where I could copy 5 words a minute 100 percent, and my study program said I was consistently 85 percent accurate, I called around for test sites. Several were available, but I decided to go to the one in downtown Houston put on by the Echo Society.

The session started at 8:30 AM. I was there a few minutes early, nervous, like the rest of the 20 or so people in the room, a cold basement in the City of Houston's Emergency Operations Center.

The VEs called for Extra Class code takers. Three people stood up and walked out of the room, trooping upstairs to the test facility and the rest of us sat back. Gene Whitehurst WA5GZX looked at the group and said all of us should have gone upstairs to take the 20 wpm test. It wouldn't cost any more, it would be good practice, and so what if you didn't pass it—what if you *did*?

I was not persuaded, but when they called for the General code test, I decided what the heck and went along. There were seven of us. The test was in a long, narrow room, tables stretching its length, with cubicle desks along one side. The test was over a speaker—scratchy and loud.

I knew I could only copy 8 words a minute max. I knew it was a waste of time, and I knew the callsigns, being important, would be repeated at the end. When the tape started, I tried my best but it was hopeless. I thought I had the callsigns, but the rest was a hodge-podge. It looked like random practice, but the test was multiple choice and I found the first callsign on my sheet. Then I froze. The next callsign on my page was incomplete, since every answer listed had a virgule—the stroke sign—and two digits after it, showing mobile operation.

I checked both ends of the message but I had missed it both times. It was a toss-up, since two choices had different answers for the same callsign so I guessed and went on.

There was a question on weather. I saw a "C" on my page and a "Y" nearby. I guessed "cloudy" and went on.

The rig being used was the next question. I had a "Y" on the page and a neighboring "U" so I guessed "Yaesu" and moved on.

In all, I made such "informed" guesses on five questions. You need seven right. I guessed on five others. On one, I might have actually remembered hearing the answer without writing down the characters, but who knows? I turned in the answer sheet and my note paper. I grinned when the VEs said they would check to see if there was one minute perfect copy. I hadn't made 20 seconds.

I went downstairs as they graded. It would be a few minutes before they set up the Novice test, one I could at least copy. The VE was using 2 meters simplex to talk room to room. They called down to say only two had passed the General code test. One of them was me.

I was stunned. They had to tell me twice—I didn't believe them. The odds were all wrong. There were so many blanks on the page, although I do well at crossword puzzles. The remainder of the testees went upstairs to take the Novice test. I panicked, thinking I would miss this chance and they would regrade the General and flunk me. They didn't.

The MFJ 20 Meter SSB Rig

More fun in the sun.

Jeff Gold AC4HF
1751 Dry Creek Road
Cookesville TN 38501

I love to operate 20 meter QRP. I got my start in the QRP mode with one of the original MFJ 20m CW rigs and a dipole. I had a blast working all over the world while I was portable and using battery power.

When MFJ came out with the 20m SSB travel rig, I just had to have it so I bought one and had a great time. We used it during a University Club QRP/ expedition, an event which really gave students a reason to want to upgrade. They had a great time operating outdoors with wires strung in the trees during the weekend. The rig did tend to drift and had a loud relay, but these weren't serious problems. The newer MFJ units are much more stable and work first-rate. The club used the little rig on Field Day and in some big DX competitions with great success.

Unfortunately, I ran short a while back and sold my original MFJ 20, so when I recently came across the newer MFJ 20 meter SSB in a local flea market, I traded immediately.

It took me a couple of days to track down a CW adapter. I installed it, re-aligned the VFO, and set up all the little adjustments on the adapter board (pretty easy). It worked well, but there was no filtering so I found it hard to operate when there a crowd on the band.

I considered building a small audio filter and putting it in the cabinet with a selection switch on the back of the rig. Then I just happened to pass a Radio Shack™ and somehow my van just pulled right into the parking lot. I asked if they had any DSP units left. The young lady, who I had dealt with before, said they didn't; they'd all been sold. But, after some waving of arms, I got her to go look and she found one out back, still on clearance for $50.

I drilled a hole in the back of the MFJ for an audio signal out jack and spliced in the speaker. When I tried it, I smelled smoke. Oops, I had to insulate it from ground.

The Radio Shack DSP really works great with the MFJ. In the CW mode, it's like a whole new radio. There are three bandwidth settings; I have found the middle position best for most of my operating, and when there is a contest I use the narrower position. I hadn't really noticed a need for additional filtering while on SSB, but, since the filter was already attached, I started to experiment with the different DSP SSB options. The noise reduction feature seems to do a nice job and the narrower filtering sometimes comes in handy. The DSP now lives securely attached to the top of the MFJ. The whole thing, with my mini dipole and gel cell, is now ready for hiking trips.

> ***"This rig and accessories can easily be packed into a small airplane carry-on bag."***

The MFJ-9420 SSB travel radio

The manual says, "Your MFJ-9420 features a very potent speech processor. Please resist the natural temptation to shout or close-talk the microphone in order to be heard! Instead, hold the mike about two inches away and speak normally." On my first contact, looking at the small rig on top of a number of much larger rigs, I found myself with the microphone up close and talking louder than normal so that my small signal would become bigger. The ham on the other end said, "You're plenty strong, but it sounds like you are swallowing your mike. Back away and don't shout." When I did, he said, "Good quality audio and a nice signal." The transmitter draws about 2.2 amps peak at 13.8 volts. The rig I tested put out 12 watts on audio peaks. The rig will tolerate VSWRs up to 3:1.

Photo A. AC4HF's portable setup, using the MFJ-9420 and a Radio Shack DSP unit. (Photo by AC4HF.)

The VFO has a 8:1 reduction-drive with ball bearings so I had no problem tuning in stations, even under crowded conditions. There's a lighted analog meter which acts as an S-meter on receive. I checked it against my commercial rig and found the readings to be comparable. In the transmit position the meter monitors the processor. It is a good idea to keep an eye on this until you get used to the rig and you'll get the same glowing audio reports I get. There's a push-button on/off switch; a push-button tune switch; which is useful with an antenna tuner; and both power and transmit lights as well as a volume control. The mike jack is a five-pin DIN for connection with a dynamic microphone. The jack accepts a standard Radio Shack 274-003 plug.

The rear panel has a standard SO-239 antenna connector. The power jack is a 5.5mm OD, 2.1 mm ID which accepts standard plugs that can be purchased at Radio Shack. There is also a mike gain adjustment. The manual explains that you may have to turn down the mike gain if you are operating under noisy conditions. There are two additional holes for the plug-in CW adapter. One of them is for the push-

button switch and the other for the key. This module wasn't available at the time I tested the rig, but I am looking forward to testing it. I like 20 meters a lot and having both CW and SSB capabilities in a small portable rig is a big plus to me.

The rig is the same size as their CW QRP rigs and operates easily off a gel cell. I've used a 4 Ah gel cell for a long period of time without any difficulty. If you are planning on operating from hotel rooms or other places where power is available, there is an optional AC portable power supply available. This rig and accessories can easily be packed into a small airplane carry-on bag. I'll be packing the rig, a small gel cell, battery charger, and a 20 meter dipole for a trip to Arizona this summer. Be listening for me.

I don't think I ever had as much fun testing a new piece of equipment as I did this rig. It doesn't have a lot of bells and whistles, such as memories, but this makes it the easiest-to-use SSB rig I have come across. My first contact was with Frank W6AIY. He reported that the audio was solid and very good quality. Mike KD1QR said, "I read about that rig and I'm more impressed now that I hear the audio."

I started to get excited about what the rig could do. I made up a cigarette-lighter power cable and stuck my 20 meter Ham Stick on the back of my convertible. I heard someone calling CQ, Lou KC2LL. He told me that the rig had great audio and a good solid signal and stated, "Can't believe how well you are doing with low power and a Ham Stick antenna."

Next was to see if anyone could hear me during the CQ WPX contest. Contests are a tough test for any rig, but I managed to make quite a few contacts using the home station five-band quad. At one point I heard a big pileup on TM1C. I gave him a call. We exchanged contest information and I snuck in the comment that I was working low power on a new MFJ rig. He came back and asked me if I really said I was using low power. When I affirmed that I was he said, "Unbelievable, you are stronger than the rest."

The transceiver was designed as a small, portable travel rig that is rugged enough to take on camping trips. The rig was not meant to be a replacement for your main station rig. It doesn't have RIT and there is no jack for headphones, but it does do a great job at what it was designed to do. It lists for $219.95 without the microphone and $229.95 with the mike—buy the mike. The AC portable power supply lists for $39.95.

The Radio Shack DSP noise reduction system

The unit is very small and light. It can operate off a standard AC outlet if you purchase the optional adapter. It comes with a power cord to operate from 12V DC. The unit is a computer controlled digital signal processor with a built-in audio amplifier and speaker. It was designed for communication receivers and its purpose is to reduce heterodynes, to reduce background noise and separate it from the desired signal.

The audio amplifier puts out 5 watts, which is more than adequate. There is an external speaker jack that lets you connect a speaker using a 1/8" plug. There are filters for CW that allow you to select one of three bandwidths. In the SSB mode you can either choose the bandwidth mode (works same as CW) or the Noise Reduction Mode (NR). The NR mode really gets out the heterodynes well for such an inexpensive unit. It has an on/off control that also controls the volume, and a power-on indicator. It comes with a mobile mounting bracket which slips on the DSP end, and hardware is provided for the car installation end. A phone jack is also included on the front panel. It is a very simple and straightforward unit to connect (the cable to connect to the rig is included) and to operate. I didn't even have to read the manual.

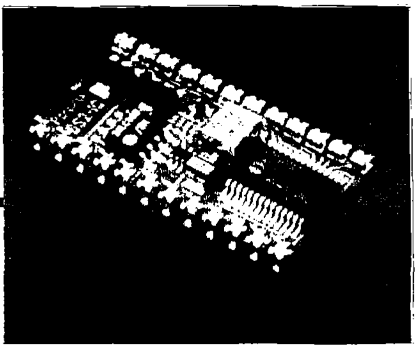
The BASIC Stamp

Wait 'til you read about this fabulous new toy!



Bob Johansen WB2SRF
61 Burnside Ave.
Staten Island NY 10302

The adage "Good things come in small packages" needs to be changed to "Great things" for Parallax's BASIC Stamp. It's a stamp-sized computer that runs BASIC. How 'bout them apples?

Currently there are three versions of the BASIC Stamp: (1) The original version, now several years old, which used two socketed DIP-ICs mounted on a small (1-1/2" x 2-1/2") PCB. It has eight I/O ports, program storage of 80 BASIC instructions, and 4 MHz operation. A small prototyping area on the board is reserved for your use. (2) The surface-mount module version of the BASIC Stamp, which is called the BS1-IC, and has 14 pin (SIP) single in-line pins. The size is about 1-3/8" x 3/8" x 1/8" thick and it has the same electrical specifications as the original version. (3) The new BASIC Stamp II (BS2-IC), which is also a surface-mounted module, has 24 (DIP) dual in-line pins. This one is just slightly longer than a postage stamp. It is only about 3/16" thick and fits into a standard 0.6" wide DIP-IC socket. It has 16 I/O ports and program storage of 600 BASIC instructions. It includes many new functions and performs much faster with 20 MHz operation.

Note: The BS1-IC and the BASIC Stamp II modules require a separate carrier board to provide power and programming connections, while a small blank area of the board is reserved for your prototyping. It is wise to buy at least one carrier board for whichever version of the stamp you intend to use so that you can program it. Afterwards, you can place the BASIC Stamp module into a socket on your own PCB to work with your own projects.

These products have come to revolutionize the way your projects can be controlled, keeping your time spent on development to a minimum. For example, BASIC Stamps are being used by model railroaders to control their train layouts. Robotics hobbyists use them to make "brains" to control their pet robots. Ham operators use them to build ID units, repeater remote controllers, etc. There are also endless industrial applications for this device.

"Its real beauty is its ability to change time durations or circuit paths quickly and easily."

Any application which previously required devices such as the venerable Signetics NE555 timer, various logic gate ICs, etc., wired together to serve a function, can be better implemented by use of the BASIC Stamp. Its real beauty is its ability to change time durations or circuit paths quickly and easily—you just change a few keystrokes during programming, instead of having to bother with the selection of resistor or capacitor values and/or hacking away with hard-wired circuitry to obtain the desired function.

Once the desired program is developed, loaded and debugged in your system, you disconnect your PC from the Stamp and it will continue to function on its own. The program is held in EEPROM (electrically erasable programmable read only memory) so that no battery backup is required for it to hold your program (for over 10 years) and it can be reprogrammed hundreds of thousands of times for different functions. They are based on Microchip Inc.'s PIC 16C56 and 16C57 RISC (reduced instruction set) based microcontrollers to which Parallax has added its proprietary P-BASIC interpreter, permanently burned into the chip's memory.

How to get started

The BASIC Stamp is programmed by using a special programming package that sells for about $100, a one-time investment for programming many BASIC Stamps. The IC module and the matching carrier boards are sold separately, and are not included with the programming package. The BS2-IC with the carrier board sells for about $70 and the BS1-IC with the carrier board sells for about $50. The BASIC Stamp alone sells for about $40.

The programming package includes an excellent instruction book with 20 different application notes, shown in detail, with both program listings and schematics, for interfacing with the BASIC Stamp. Some examples of these applications are interfacing to an LCD panel, keypad, A/D converter, servo, a stepper motor, sensing temperature and humidity, sending Morse code, infrared control, sonar range finding, and solar power.

The BASIC Stamp II, which is Parallax's new product, has

additional capabilities so they now include an additional booklet with the programming package. Besides the increased I/O lines and speed, the two most outstanding new features are XOUT X-10 (power line remote control code transmission) and DTMFOUT (DTMF tone generation).

You'll need a PC with at least 128K RAM running MS-DOS 2.0 or greater. One 3.5" HD disk is provided with the programming package. The BASIC Stamp uses the Parallel printer port with three wires to the DB-25 plug interface hookup. The cable is provided with the programming package. The BASIC Stamp II uses the computer's serial port; a DB-9 cable is provided with the programming package.

The Stamps are powered most conveniently, using a standard alkaline 9V transistor radio type battery which snaps directly onto the carrier board.

I can recall my first experience programming my first BASIC Stamp. Within five minutes, I loaded in a short program, which made an LED that I'd connected to one of the I/O lines blink. I was very excited about being able to control a device through my PC keyboard. The next thing I did was hardwire a DTMF decoder IC onto the prototyping area and develop a program to decode touch-tone commands. I made several remote control devices with the BASIC Stamp to use with a pair of HTs.

Now I'm hooked not only on soldering components together, but also on sketching flow charts and developing programs to try out with the new stamp in my collection, the BASIC Stamp II. Try one—you'll like it!

For more information contact: Parallax, Inc., 3805 Atherton Road #102, Rocklin CA 95765. (916) 624-8333.

Persistence Wins

Continued from page 25

I was still in shock when I went upstairs to take my Novice written and I thought I did okay. I was sitting down when I heard over the simplex, "Tell Mr. Waters he will have to take another test." I thought this meant I had failed the written. I thanked the test staff and left to join my sons on a Scout trip, thinking I could always take the Novice written again.

I started studying again that night, and I wondered how I had failed when I did so well on the computer.

On Tuesday night, I got a letter from Gene Whitehurst asking me why I had left without taking the Technician written, since there would have been no additional charge. He enclosed the CSCE—for 13 wpm and Element 2. I would be receiving my license in six weeks. I went to work that night on Technician study, thinking I had only a year to pass General written. By June, though, I had done it. I got my General license in August.

I thought there I would stay, never hoping to get to 20 wpm and Advanced was a 500-question pool, but a fellow lawyer called up—Madison Jones, then KB5ZMH. He wanted to say hello. We became friends. Then the so-and-so upgraded to Extra (AB5TV) and started talking about less crowding for QRP contacts.

I bought the Advanced study materials, which is all regulations, procedure, theory, and antennas, my favorite, and took the test on a Saturday. I wasn't ready. The computer

How Much Are Those Decibels Worth?

A survey of amplifier costs and the resulting S-units.

Bill Clarke WA4BLC
764 Alta-Voor Road
Altamont NY 12009

Thinking of purchasing an HF amplifier? What output do you want: kilowatt, legal limit, or California kilowatt? Perhaps you're happy to operate with only 100 watts, which is the typical output of today's transceivers. So what is the *real* difference in signals at the receiving end, as compared to the output signal at the transmitting end? And what are the dollar costs for these S-meter differences?

First, a basic: Each time the final RF output power is doubled, there is a power increase of 3 dB. A gain of 3 dB on HF is generally considered to be the least discernible change at the receiving station. An increase of 6 dB is one S-unit and can be considered a worthwhile gain (Note: S-units vary between receivers, though they shouldn't). The following dB gain figures are based upon an initial RF output power of 100 watts:

Amplifier Gain	Power Output
6 dB	400W
9 dB	800W
10 dB	1000W
12 dB	1600W
15 dB	3200W

Small amplifiers

A power gain of 6 dB can be achieved with a small amplifier which usually uses four sweep tubes. These amplifiers offer an economical entry to moderate RF power gains; however, they must be handled carefully since the tubes won't stand prolonged tune-ups. Such amplifiers were plentiful a few years ago; however, I am unaware of any being made now. There are several different models available used, generally selling for $150–$250.

Kilowatt amplifiers

The next step is the kilowatt. Used kilowatt amplifiers generally use four 811A tubes, two 572B tubes, or a single 3-500 tube. New kilowatts use either the single 3-500 tube or four 811A tubes. Output levels are around 800-1,000 watts, for a 9 dB or 10 dB increase above our 100 watt input level. New kilowatt amplifiers cost from $1,100 to about $1,500. Used kilowatts start at about $300 (more if you want 160 meter and WARC band coverage). One exception to these prices is the Ameritron amplifiers using the 811A tube. The three-tube unit (AL811) is rated at 600W output and sells for under $600. The AL811H uses four tubes at 800W and sells for a little over $700. It's a new amplifier at a used amplifier price, and the difference in dB between 600W and 800W isn't really significant. In between the kilowatt and the small sweep tube amplifier lies an area of 500W and 600W solid-state amplifiers. Generally, these are easy to operate, requiring no tune-up. Some models interconnect with the transceiver and track band changes and/or make antenna selections. Prices vary from $1,100 for the Ameritron ALS600 (with a built-in power supply) to nearly $3,000 for a full-featured ICOM IC-2KL. Solid-state amplifiers require no tuning and produce no filament heat. They are, however, expensive for the amount of power gained!

> **"You don't need an amplifier to make contacts, but it sure can make life easier."**

QRO

The last legal step is the full-power amplifier, capable of developing the amateur limit of 1,500W PEP output. Amplifiers in this power class typically use two 3-500 tubes, a single 3CX-1200A7, an 8877 tube, or a 4CX-1600U. Many of these amplifiers are capable of producing slightly more output than that legally allowed.

More than the law allows? Let's look at the 3 dB rule again. In order to make a discernible difference at the receiving end, your output must increase by 3 dB. That means you'd have to increase your 1500W legal limit to 3,000W to make a difference on the other end. The difference between running your amp at 1,500W and at 2,000W will not be noticed. It is, however, illegal!

New amplifiers in the legal limit class generally sell in the area of $1,800 to $2,300. However, top-of-the-line units such as the Alpha series sell for up to $6,000. Used 1,500W amplifiers start at about $800 (more for 160 meters and WARC bands).

The cost of decibels

Here is the lowest cost you'll probably find for each power increase:

Amplifier Gain	Power Out	New Cost	Used Cost	$/dB
6 dB	400W	N/A	$150	$25
9 dB	800W	$700	$300	$78
10 dB	1000W	$1000	$500	$100
12 dB	1500W	$1800	$800	$150

Notice the difference in dollars/dB between an 800W amp ($78/dB) and one that puts out the full legal limit ($150/dB). If you invest $1,100 more to get from 800W to 1,500W, the S-meter on the receiving end will go up about *half* of an S-unit. Is it worth it? Only you can decide. The cost-per-dB ratio gets even higher as you consider better equipment. A full-featured kilowatt output solid-state amplifier, such as the ICOM IC-4KL, lists for nearly $9,000, or $900/dB.

Used amplifiers

Older amplifiers, such as the Heathkit SB-200, using two 572Bs, or the Collins 30L1, using four 811As, make excellent general-use kilowatt amplifiers. You may need to use a relay box on the keying line to protect some solid-state transceivers from high switching voltages. Many older amplifiers sell on the used market for $300 to $600, depending upon their appearance and tube condition. Be aware that 160 meter and WARC band coverage does not exist on most older amps, whether kilowatt or legal limit versions.

Tubes

Tube costs are a factor when buying any amplifier, since at some point in time you will be faced with buying a replacement. The tubes in used amplifiers are always an unknown factor and replacement costs should be considered prior to making a purchase.

Sweep tubes sometimes sell for less than $10 each, but can go higher than $20. For other amplifiers, the Russian-made Svetlana 811A tubes sell for under $20 each, 572B pairs sell for about $95, and 3-500s start at about $110. When you get to the more exotic tetrode tubes, the prices go up quickly: 3CX800A7 at about $300, 3CX1200A7 at just over $400, and 8877s at better than $600 each.

Remember, a kilowatt will sound the same regardless of what tubes are producing it.

When a kilowatt is not 1,000 watts

Watch out for those advertised power claims; they can be devious and misleading due to confusion between input and output power. Generally, a good amplifier will be about 65% efficient. This means that a manufacturer may refer to an amplifier with one thousand watts input as a kilowatt; however, that amplifier would only provide 650 watts output. The examples used in this article are based upon output power.

Amplifier observations

You don't need an amplifier to make contacts, including DX and contesting. There are thousands of hams using 100 watt transmitters and wire antennas, all enjoying their share of DX and contests. It is the antenna first, then the power level, that counts, and somewhere between the two is the operator whose skills bring about many more contacts than brute force alone.

Seldom do local contacts (75 meter nets, for example) require the use of an amplifier. After all, we are supposed to use only the power necessary to maintain communications. Unnecessary amplifier use serves to clog up the bands with QRM and make the electric power companies richer.

Too often an amplifier is used as the means to attain a good signal report, when the same good report could have been had if the antenna system was improved (at much less cash outlay than the cost of an amplifier). This statement is very often the case on 160 and 75 meters and, to a lesser degree, applies to other bands as well.

A directional antenna such as a three-element yagi or a two-element quad will concentrate your signal and give about 7 dB gain in a single direction (using a 100W transceiver, this is the equivalent of 500W into a dipole). A tower and yagi/quad can be expensive; however, there are many wire antenna configurations that are equally effective, costing only a few dollars and requiring only a little time to put up.

Some bands, such as 15, 12, and 10 meters, do not play the amplifier game well. Propagation-wise, these bands are either open or they are closed. No amount of power will routinely support communications at a level any greater than 100W will do.

A place for amplifiers

It is not uncommon for an amplifier to make the difference between getting through and getting that QSL. As an added feature, amplifiers are nice in the winter. The ones with real tubes provide a warm glow in the shack and help heat it as well!

Persistence Wins

Continued from page 29

said I was only averaging 32 to 36 right, and you need 37 out of 50.

I had bought Gordon West's tapes, Jerry Ziliak's tapes, and Radio Shack's book (also by Gordon). I finally committed two formulas to memory. The test was at a library. The answer sheet had two rows of blanks. You go down the sheet, filling in the blanks, then start out at the top of the other half of the page. I finished and turned it in.

One of the VEs started grading. He ended the first row of 25 questions with only three marked wrong. He looked up and said, "So far, so good." I missed five on the other side.

"Take the Extra," the VEs said.

"I'm not ready," I said.

"If you haven't studied, you won't pass it, but take it anyway," they said. "It will be good practice and you never know." Where had I heard that before? I took it, and, as I was turning it in, I saw a ham I knew, Maurice, sitting at the VE table, turning in his 5 wpm test for the Plus upgrade.

"I think I could have passed it if you'd have let me write down the dots and dashes," Maurice said. "Then I could have gone back and transcribed."

"Ha! The Wayne Green Novice Code strategy," I, a *73* subscriber, thought.

The VE leader said, "I never said you couldn't do that," and the room fell silent. Maurice looked at him for a full 10 seconds.

"I'd like to take another code test, please," he said. I turned in my Extra written. It wound up with a lot of red on it—my first ham test failure.

"You didn't do so well that time," the VE said, handing me a CSCE for Advanced. Even so, I was higher than a Gigahertz (Maurice got his upgrade, too). Today I bought the Extra book, and the 20 wpm tapes. Nothing ventured...

JPS Communications NIR-12

Continued from page 24

can pull out a certain voice with a center frequency of 1100 Hz and a 1000 Hz bandwidth, copying voice frequencies between 600 and 1600 Hz. It's like the IF pass control on some receivers.

Those are the four modes available with this filter. A significant advantage of the NIR-12 is the ability to use them all at the same time, including cutting the bandwidth when using the NIR mode, as I mentioned.

Some of the artifacts created by the NIR mode can be reduced by using the dynamic peak mode, and, many times, both can be adjusted for best overall noise reduction. Of course the notch filter is always useful with voice modes.

Additional features

You can also use an NIR-12 for transmit audio processing. This is most useful if your microphone is picking up a lot of ambient noise. You'll have to provide your own switching and preamplification if you want to use the same unit for transmitting and receiving, but there's no provision for resetting the controls for different transmit and receive settings, so you're better off using the unit on either TX or RX — but not both.

The NIR-12 provides a line level output that's not controlled by the volume control for things like TNCs, RTTY demodulators, or modems. A headphone jack for both stereo and mono headphones is also on the rear panel. A "bypass" position lets you switch the unit into bypass mode through your transmit/receive relay so you can monitor your transmitted signal (especially CW) without going through the NIR-12's delay.

The instruction manual is comprehensive and clear. It has sections providing a brief description, and instructions for quick operation, controls, and operation. The result is that a cover-to-cover reading of the manual reveals the same information in varying detail three or four times. This may lead to some head-shaking, but you *will* know how to use it by the time you're done.

You also get a schematic; it's barely readable, but JPS is to be commended for putting one in at all. There's a programming interface available if you want to develop your own filter algorithms, and there's a section on the limitations of the NIR-12. The reality is that there are still some signals that are so far down in the noise you can't hear them, even with 1996 technology. Obviously noise algorithms and more powerful processors are needed and will continue to evolve.

Since the DSP chips need time to do their thing, there is a measurable delay through the unit, especially in NIR mode, where the delay of 130 milliseconds renders the TOR modes unusable in normal ham operations. For all the other modes, the delay is specified as less than 19 milliseconds, which allows normal TOR operations.

The NIR-12 is better than the NIR-10 in every way, but we still have a way to go before I will stop complaining about computer noises! The emitted RFI from the NIR-12 is far less than that of the previous model, but there's still a little and for some reason it still carries the less restrictive FCC Class A rating. Equipment that's well-shielded for home use normally carries a Class B rating.

The other noise is what comes out of the audio output. Again, it's better than the NIR-10 and better than some competing units, but I still hear its microprocessor running in the background through the speaker. JPS rates the output at 2 watts with 10% distortion. I'd prefer less, and DSP units that are 10 times the price achieve that.

For my money, I haven't yet found anything better than the NIR-12; it works well, and JPS's reliability and customer support are superb. They have regularly come out with customer-installable firmware updates for their units. I continue to use the unit for ham radio and broadcast monitoring, where I can set up the unit and know that the tape I'm recording won't be ruined when I turn on a computer. While it isn't the only noise reduction I have, it is the most generally effective.

QRX . . .

Continued from page 9

from the village, many with only the clothing they were wearing. Most evacuees were taken to nearby Waupaca.

Amateur Radio Emergency Service (ARES) personnel contacted State Director of Emergency Government, Al Shanks, later that morning, who instructed ARES to activate communications and set up a command post at the Red Cross Center in Waupaca. At DEG's direction, amateurs also provided communications for the incident command post at Weyauwega, at the Fremont WI Fire Station (where all the Weyauwega fire department's equipment was taken to be housed and maintained), and at a road block check point at State Highways 10 and 49.

Communications were provided for Red Cross shelters in Waupaca. Circuits were also active from Waupaca to the State Emergency Operations Center of the DEG in Madison, where RACES station WC9AAG was in operation 24 hours a day for nearly two weeks. Two meter repeaters, the 3993.5 kHz RACES frequency, and some packet radio nodes were used for the long-haul path to Madison.

Ham Radio Operator Lauded for Helping Save Sinking Yacht

Los Angeles: As an amateur radio operator, Bob Karon has frequent conversations with people from around the world, swapping stories about family, sports, or new radio equipment with other enthusiasts.

But a recent transmission, heard as he was testing a new amplifier, sent the 46-year-old ham operator from Los Angeles leaping to his feet; a frantic voice was calling, "Mayday! Mayday!"

Within seconds, he had begun a search by radio and telephone that, with the assistance of the U.S. Coast Guard, ended in the rescue of four people aboard a yacht sinking in the Caribbean Sea at night with a storm moving in.

"This all came out of the blue," he said after receiving a letter of commendation from the Coast Guard. "I wasn't expecting an emergency call."

The night of March 18, he was speaking with another ham operator in Naples, FL when he heard the mayday call on the same frequency.

In the first few minutes of talking to the sinking craft, Karon found out that it was a 44-foot Canadian yacht named the Cambria, carrying owner, Kenneth Cunningham, his wife, and another couple.

The yacht had been grounded on a reef about 150 miles southwest of Jamaica, Cunningham indicated in static-interrupted transmissions.

The yacht had a hole in it, water was coming in fast, and a storm was approaching. . Cunningham said that the waves were growing and the boat would go under within the hour.

"They sounded terrified," Karon said. "It sounded like they had very little time."

Karon first telephoned the Coast Guard in Los Angeles, and was transferred to the Miami station. With the phone to his ear and microphone in hand, Karon was the only link between Cunningham and the potential rescuers.

"I had to make sure (the Coast Guard and the sailors) got absolutely correct information about the yacht and its location," Karon said. That turned out to be very difficult.

The grounding left the vessel on its side on the reef and jolted the communications system out of place, including the radio antenna, which was almost touching the water, Cunningham told Karon.

"The signal was weak and full of static," Karon said. "A lot of times I would say something and the response would come back, 'Negative,'" Karon said, meaning Cunningham was trying to correct him.

The Coast Guard determined that its closest rescue team was 2 1/2 hours away, but the Nord-Jahre-President, a freighter, was about 25 miles away and could reach the Cambria in an hour and a half. It might be too late, Cunningham told Karon, but it was their best chance.

Karon was connected by the Coast Guard to the Nord-Jahre, which accepted the mission, changed course toward the Cambria, and took over for Karon, who learned the rest of the story when he got the letter from the Coast Guard.

"Your professional and humanitarian actions are heartily commended and demonstrate the finest traditions of assisting mariners in distress," said Coast Guard Capt. Robert Gravino in his letter to Karon.

"This is the first time that I know of that someone picked up the call before the Coast Guard," added Petty Officer Scott Carr, who aided in the rescue from the Miami station. by Jose Cardenas, *Los Angeles Times*. Reprinted from *Sarasota Herald-Tribune* / Sunday, April 7, 1996.

Home-Brew Whip Antennas

Make field-strength whips from your basement junk pile.

J. Frank Brumbaugh KB4ZGC
PO Box 30 C/O Defendini
Salinas PR 00751

Many hams would like to have a cheap and simple way to make collapsible whip antennas that would mate with field-strength meters and other test equipment. Others would like to replace the rubber ducks on their handhelds with quarter-wave whips. A whip which would collapse to about six inches and extend to about 19 inches could be used on the 2 meter, 1-1/4 meter and 70 cm bands, and would be ideal for a dual-band transceiver.

Many mail order dealers offer small collapsible whip antennas that vary in length, diameter, and number of sections. However, usable whips can be salvaged from old TV rabbit ears and small AM-FM radio receivers.

Depending upon the outside diameter of the base of the whip chosen, it can be mounted in a UHF or BNC connector so it will mate with similar connectors on your ham equipment. A BNC to UHF adapter will enable a single whip to be mated with either connector on equipment. The exploded views in **Fig. 1** illustrate clearly how to mate a whip to a male connector, both UHF and BNC.

Solder a short length of bare wire to the base of the whip. It may be necessary to file through the shiny coating on the whip to allow the solder to adhere adequately. Use of a solder gun is recommended because of the thermal mass of the whip.

UHF

Insert the wire from the base of the whip through the center contact in the plug body. Making certain the wire and whip base do not touch the body of the connector, solder the wire into the center contact. While holding the whip centered in the plug body, inject hot glue or epoxy cement into the space between the whip and the plug body. More hot glue or epoxy can be injected through the solder holes in the plug body: this will strengthen the bond. When the glue has cooled or the epoxy has set, slide the sleeve of the PL-259 over the whip and screw it into place on the plug body. Use an ohmmeter to make sure that there is no short between the whip and the plug body, and that the whip and center contact are continuous.

BNC

The wire soldered to the whip must be thin enough to fit into the hole in the end of the contact pin. Cut this wire to a length that, when inserted into the contact pin, which is then inserted fully into the plug body, ensures that the base of the whip is within the plug body and that no short to the body exists. This may require some cut-and-try. When it's at the proper length, solder the wire into the contact pin and remove any excess solder from the outer surface of the pin.

"Usable whips can be salvaged from old TV rabbit ears and small AM–FM radio receivers."

Note: Discard the nut, washer, gasket and clamp from the BNC: these will not be used.

Insert the contact pin into the plug body and make sure it is firmly seated. The base of the whip must be partly inside the plug body, but not shorted to it. Inject hot glue or epoxy into the plug body between it and the base of the whip. Hold the assembly until the glue or epoxy is set, making sure the whip is not shorted to the plug body.

Additional hot glue or epoxy can be mounded into a fillet around the whip and plug body of the BNC connector, or the PL-259 if this is used. This will add strength and provide a neater appearance. Use a wet finger to mold the fillet into a neat appearance. Always check with an ohmmeter for continuity between contact pin and whip, and for no short between whip and plug body.

LETTERS
Continued from page 6

scene). It is little wonder that many drop out after a year. Shame on you, Wayne, you should know better, but I do understand your frustration. I am one of those who has upgraded. I'm into weak signal VHF SSB, Mode A satellite, packet (home-built BayCom), and Ham-Com CW, RTTY, etc., decoder to decode VHF beacons. Yes, amateur radio is dying, but more accurately is committing suicide. Sure, there has been a dramatic increase in No-Code Techs. It will be interesting to see what percentage of these will renew over the next 10 years. I'll bet it'll be less than 25%. Combine that with the age of the higher class license holders and the future doesn't look good. Perhaps we should replace the CW requirement with tougher exams, including up-to-date technologies.

Mike, I've operated CB in dozens of cities and never had a bad experience, so I feel no shame about CB. I've had some wonderful contacts with interesting people and found most of 'em very helpful to visitors. Yes, the code is perceived as an ogre all out of proportion to the actual difficulty it presents, but we have to deal with this religious belief, not reality. Many of us spend lifetimes not taking a relative few minutes to do things that would make our lives much more fun. Like dieting, for instance. Or eating more healthily. Or improving our educations. As the sunspots heat up our lower bands are going to get hot too, and those poor suckers trapped on 2m are going to miss out on an incredible amount of fun. So, let's try to break the ARRL's insistence on the code test, but let's also make sure those marooned in the ham attic on 2m know what fun they're missing downstairs ... Wayne

Edward Slabe N8TQP. On the very last page of the May issue, in the "Updates" column, you ask for input by anyone who has purchased and built the Super CW Station which *73* featured in the June 1995 issue. Well, let me tell you about my experience with Sam Ulbing and his incredible CW-keyer-reader-tutor-clock.

The assembly was very straightforward and the well-written assembly guide made building the SCS (as Sam calls it) a lot of fun. During assembly I had a few questions on the SCS and was impressed by how quickly Sam answered my questions when I E-mailed them to him.

I've never had so much fun working on Morse code as I have had with this unit. Why? Because this keyer also shows you how well you are sending as your copy scrolls across the screen. I'm sending good copy because I can see how it sounds to those listening. When I send a "C" it won't sound like "N N." And sending is only part of the fun. The other night I was listening to a QSO between two stations who were using keyboard keyers. So what's the big deal? They were sending to each other at 40 words a minute. I followed the entire QSO without missing a single word. Now I am really impressed with my SCS unit. It really held on to the signal with only very slight adjustments of the RIT control over a period of 20 minutes without losing a word as the signal dropped down to an S-2. The tight bandpass of the code reader ignored the noise.

The best part is that I can use the SCS anywhere. It is not tied to a computer. This is great; now I can sit out in the back yard under a nice shade tree with a QRP rig and my SCS. This is the way to enjoy having a relaxed conversation on CW. And if you have a keyer built into your rig, just use it and the SCS will display your copy using the sidetone from your rig.

This unit far exceeded my expectations. I not only have a ball honing my CW skills, I also have a great keyer, and as I grow tired and start missing some of the conversation I can look at the LCD and check my copy.

If anyone is thinking about a keyer, a CW tutor, or a CW reader, you should contact Sam Ulbing and check out his Super CW Station. It is to CW and ham radio what Superman was to crime fighting. The fun is only

The JB Keyer

A low-tech solution to good keying.

Richard Koelker KU8K
550 Stanley Road
Akron OH 44312

What has no tubes, no transistors, no ICs, no keyboard, yet can make machine–like Morse code? The JB Keyer.

The JB Keyer makes self-completing dots and dashes. When idling, it takes zero standby current. It's not very sensitive to power supply voltage and takes about 25 mA from a 12 VDC source when generating characters. It can be cheap, depending on your junk box. It need not be much, if any, larger than a keyer built using ICs.

"The JB Keyer can be cheap, depending on your junk box, and it need not be much, if any, larger than a keyer using ICs."

The schematic for the JB Keyer is shown in **Fig. 1**. Several of these keyers have been built using relays and capacitors removed from old circuit boards. All provided acceptable performance without careful parts selection. It should be noted, however, that electrolytic capacitors are generally wide tolerance parts (+80% to −20%, for example), and in some cases parts may need to be hand–picked. The pull-in and drop-out characteristics of the relays used also affect the speed and mark/space ratio.

How it works

The JB Keyer makes use of the difference between the "pull-in" and "drop-out" voltages of the relays used, in combination with RC time constants that change when these voltages are reached. Refer to the schematic diagram in **Fig. 1**. Relay K1 and the components on the left side of the schematic dictate the "on time" or "mark" of the keyer; relay K2 and the right hand components determine the timing of the "off time" or "space." When the key lever is pressed to the DOT side, capacitor C1 is charged rapidly through the normally closed contacts of K2, in series with resistor R1. R1 is chosen to be large enough to limit the peak current through the key con-

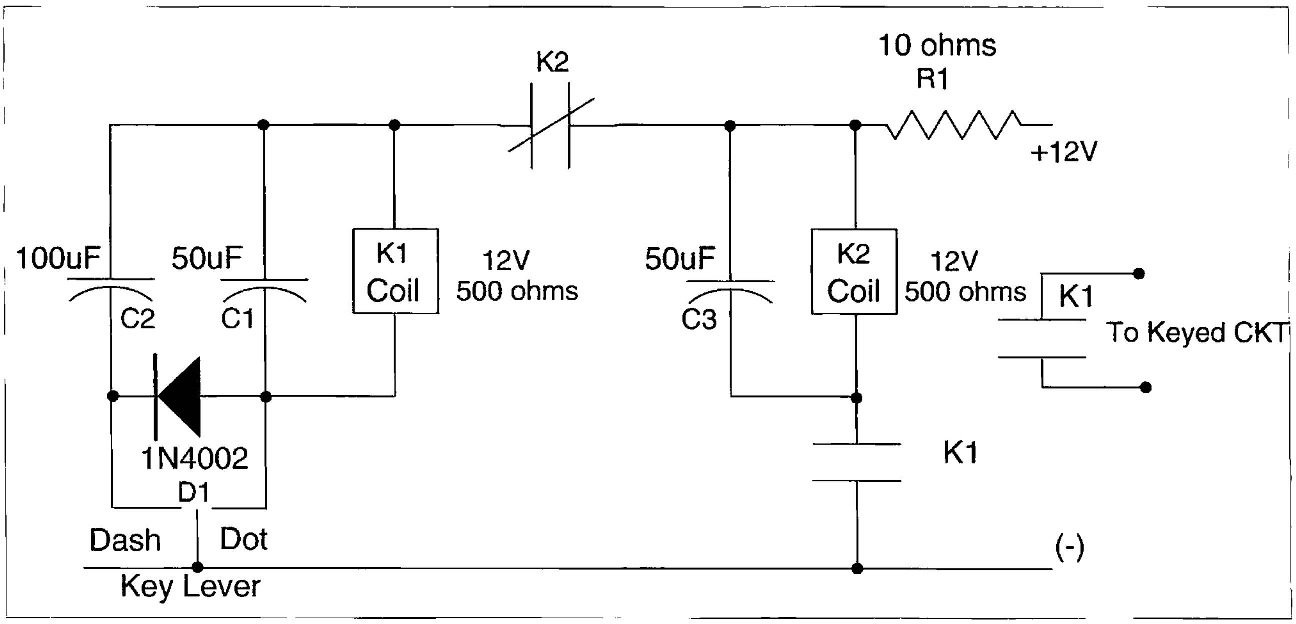

Fig. 1. Schematic for the JB Keyer.

tacts, but small enough to allow C1 to charge rapidly (before the key contact is opened). As C1 charges it will pass the pull-in voltage of K1, causing it to operate. When K1 operates, it closes its normally open contacts, completing the circuit for C3 and R1. When C3 reaches the pull-in voltage of K2 the relay throws, opening the current path to C1 and K1. Even if the DOT contact is still closed, K1 will be unable to pull in again until C3 discharges through K2. If the DOT contact is held closed, the K1-C1 time constant will determine the "dot" timing, and the K2-C2 time constant will determine the spacing between dots—which should be equal to the length of the dot itself. A second set of relay contacts of K1 keys the transmitter, ideally with a 50% duty cycle if both the left and right time constants are equal.

By definition, a dash is the length of three dots. If the DASH contact is closed, C1 and C2 appear to be in parallel (through D1) and their values add. The dash time constant therefore consists of C1 + C2 combined with K1, and will be three times as long as the C1-K1 combination. The dash will be self-completing as before, and the space following it will be the length of one dash, as expected.

Choice of relays

The coils of the relays used in my versions of the JB Keyer are rated at 12 VDC and have 500 ohms of resistance. These relays will pull in at less than 12 volts and, once energized, will stay thrown when the voltage across the coil drops well below the pull-in voltage. These relays, therefore, have a type of "hysteresis," which is essential to the operation of the JB Keyer. Although they will not pull in at the lower voltage, they do not drop out, once energized, until the voltage across the coil falls to the lower value as the capacitor across it discharges. Virtually all relays have some amount of hysteresis, so it's worth experimenting with whatever you have in your junk box.

Capacitors

Because of the high capacitance values required, the only practical types to use are electrolytic types. These capacitors are polarized and can be installed correctly in only one way. Polarity markings must be observed! These capacitors are generally wide tolerance components. If marked 100 µF, the actual value of an aluminum foil electrolytic capacitor may be as little as 80 or as much as 180 µF. On the other hand, another type of electrolytic capacitor, the tantalum electrolytic type, can be obtained in closer tolerance values, but they are more expensive.

In addition, as electrolytic capacitors age, their capacitance value decreases. Many radio and television problems are due to dried-out electrolytic capacitors. The humming often associated with old tube-type radios is usually an indication that dried-out electrolytics need to be replaced. The only sure way to know the condition of an electrolytic capacitor is to test it with a capacitance tester or substitute a known new one.

In other words, if you use salvaged capacitors you may have to experiment. On the other hand, *all* of my parts were salvaged and performed acceptably. While new capacitors will probably be higher than their marked value, used ones may be off considerably from their nominal value in either direction, but probably on the low side.

Speed control

The capacitance values for the original model of the JB Keyer were chosen to provide a comfortable speed for mobile operation. In the interest of small size, no speed control was provided. A hi/lo speed operation can be obtained by switching in fixed resistors across both relay coils. 1,000 Ω is a suitable value. A two-gang variable resistor in series with these added resistors would give continuously variable speed.

Construction

The relays specified have their contacts arranged on a 0.1-inch grid. The keyer was constructed using point-to-point wiring on a 1 x 2-inch piece of scrap perf board. The small size of the JB Keyer allows you to tuck it away inside the transmitter, if you want.

In case you wondered, the "JB" in JB Keyer refers to the origin of the parts used in the circuit—my Junk Box.

Lubricating a Transceiver's Fan Motor

Cut down on background noise and prolong the motor's life.

Dave Miller NZ9E
7462 Lawler Ave.
Niles IL 60714–3108

The fan motors in most amateur 100 watt HF transceivers should be lubricated every now and then, particularly if their sound changes noticeably. These fans are absolutely essential for keeping free air moving in and around the transceiver final amplifier's heat sink, even more so when using the rig on AM, FM, or any of the data modes. The fan motors in my two Kenwood TS-430S HF transceivers became noisy recently, so I was more or less forced to remove and lubricate them. What follows is a detailed explanation of the procedure that I used in the TS-430S, but it will apply in part to other transceivers in the same class.

"Resist the temptation to simply 'shot-gun' spray the little guy; it will likely do as much harm as good."

Getting inside

The motor in the TS-430S is easily accessed by removing the four Phillips-head screws around the plastic "fan guard" that faces rearward on the transceiver. Then there are three more, recessed and smaller, Phillips-head screws to be removed in order to free the fan motor from its mounting configuration on the transceiver. Mark the terminals "+" and "-" and unsolder the shielded coaxial-type cable that feeds 12 VDC to the motor. Now it's completely free. The bracket with the three mounting "ears" can be left on the motor's housing for the rest of the operation.

Now for the fun part! The motor bearings are not accessible from the outside; the motor's housing has to be disassembled to gain access to these bearings, where the oil must go. Resist the temptation to "shotgun" spray the little guy; it will likely do as much harm as good, since the oil needs to be only in the bearing surfaces themselves. First, remove the white plastic fan blades, loosening the tiny straight-blade set screw in the mounting collar. Unfortunately, the motor that Kenwood uses can't be "cleanly" disassembled by unscrewing nice little screws. There are two small bent-in tabs holding it together instead! The only way to get it apart is to bend those two little tabs up and slip the rear white plastic end-bearing housing away from the main steel motor housing section. This means you can't take it apart too many times before the tabs break off, so try to do a good job the first time around. I used a small jeweler's screwdriver to start the bend in those tabs, finishing with a small pair of long-nosed pliers.

In my own motors, the inside was clean, but without any noticeable lubrication. I used a Teflon®-based lubricant (Radio Shack™ # 64-2301A) myself, but any of the modern, long-lasting lubricants intended for high speed should work well. You'll want to apply just a small amount—a couple of drops—on both the front and rear bearing surfaces (where the motor's shaft touches the motor housing bearing surface). To get to the front bearing surface, you'll have to pull out the rotor section, overcoming the resistance of the magnets around it, and apply the oil to the shaft surface just forward of the windings themselves. The rear bearing is a bit easier, since there's a small "cup" and plastic washer at that point. A "pinpoint" lubricator, like the one mentioned above, is almost a must.

There should be no need to remove the rotor winding assembly from the commutator's bushes, but if it happens accidentally while working on the inside of the motor, the rear shaft of the rotor can be reinserted into the rear bearing cup, with the plastic washer in place (its shoulder pointed toward the commutator segments) and the brushes very carefully spread and placed once again against the commutator. The brushes are very delicate but do have a fair amount of spring in them, so take your time and you should have no trouble with the task.

Now carefully slide the assembly back together and bend the two locking tabs back down far enough to hold the housing securely in place. Run the motor for a few minutes on your workbench, using a small 12 VDC power supply, or even a 9 volt battery. If everything seems well, solder the cable back on and reinstall the fan motor package. In both cases, with my units, it made a tremendous difference in the amount of noise generated by the fan motor during operation, which was almost unnoticeable after a good lubrication.

There's a good chance that the small motors used in other ham transceivers for cooling the final amplifier's heat sink are constructed in a similar manner, though some may be more easily disassembled because thay have small screws instead of a locking-tab construction. So don't be afraid to give it a try, regardless of the particular transceiver you might own. Just do it carefully, when you're not rushed, and document your steps as you go, noting the correct placement of any small parts within the motor's innards. You'll prolong the life of the motor significantly, as well as cut down on the background noise in a positive way.

NEVER SAY DIE

Continued from page 7

hams were teen-agers. Today it's around 12%, tops. That's not the key to keeping the hobby alive.

Sales point #1 is fun. It's fun to make friends over the air. It's fun to work DX. Amateur radio is a whole bunch of fun hobbies, which I try and cover with articles and columns in *73*.

Sales point #2 is the fantastic career path that an interest in amateur radio provides. I hope there's no argument that the world is going to need millions of technically literate workers in the 21st century. The electronics, communication, and computer industries are going to need people to develop, build, sell, operate, and maintain the electronic systems of the future.

Sales point #3 is adventure, and amateur radio has plenty of that if you have the guts (aka initiative) to take advantage of the opportunities. My life has been filled with adventure as a result of my interest in amateur radio.

I was having a ball experimenting with 2-1/2 meters back before World War II. Heck, 10m was still mostly an experimenter's band in those days. I built my first 2-1/2m walkie-talkie in 1939 and wrote about it in the school literary magazine. When my ticket arrived, I made my first contact with it, working Dexter Miller W2MSV, as I was walking along the street. Today I'd use an HT that fits into my shirt pocket, but then my walkie talkie was in a Bud box about 10" x 10" x 10".

Came WW II and my first really big adventure. I joined the Navy in 1942 as a radio technician and went to their electronics schools. That led to my being assigned as an Electronics Technician to the *USS Drum* in 1943. After five exciting war patrols, I was transferred to the Submarine Base in New London (CT) to teach electronics in 1945. You can read about my submarine days in my *Submarines in WWII* book ($8). I got discharged in 1946 and, not knowing any better, went back to college.

Then there was my adventure as KC4AF on a DXpedition to Navassa Island in 1958. Now, that was exciting, complete with riding out a hurricane, and almost getting killed a couple of times. And my being appointed to the US team to represent amateur radio at the ITU in Geneva in 1959. And how about Operation World-Wide, where I operated from an Air Force C-54 as we flew around the world, visiting 23 countries?

Less epic, but still exciting, were my many mountaintop VHF expeditions. How about working seven states on 10 GHz? Adventure is there if you keep your eyes and ears open.

Like operating from Swaziland and Lesotho. Or even a few days operating from St. Pierre Island, just a short flight from Halifax. Or cranking the generator for Field Day on a bicycle (last year at Boulder).

Every now and then I get a letter from Ken Miller K6IR from some weird place or visiting with someone famous, all as the result of amateur radio. Ken and I had a great time visiting Asia together. Several times. I used to escort groups of up to 250 hams and electronics people on tours of the Asian electronics shows every October, attending shows in Tokyo or Osaka, Taipei, Seoul, and Hong Kong. Every trip was an adventure. I can't wait to set up a web site and put about 10,000 color slides of my trips on it. Plus pictures of hundreds of well-known hams.

I've been asking you about your ham adventures, so how about it? Well, when talking with the kids, you can point to what's possible in the way of adventure.

Now let's get those kids excited and licensed.

Meihem

When a manuscript came in from Ray Eisner proposing an updating of English spelling which might be launched via amateur radio, I remembered a wonderful story in *Astounding Science Fiction* 50 years ago, back when I still had a full head of hair. There was a story, "Meihem in Ce Klasrum," by Dolton Edwards, which made a lot of sense. Well, Ray has picked up the ball for us.

How come English has so many letters that aren't pronounced, but have managed to stay in the dictionary, much to the frustration of children and foreigners trying to learn our crazy-quilt language? A couple hundred years ago they *were* pronounced. It's just that we've had several generations of lazy talkers since then, so today we pronounce tough as tuf and might is mite, don't you k-no-w?

The main problem I found with Ray's well-thought-out article was that it was 16 pages long! Yoiks. Also, there was just the tiniest question in my mind as to whether 100% of the readers would be as excited about the whole idea as I. People will go to extremes not to change habits and here was an idea for updating our language which meant making a big change. If Ray had proposed just one little change it might have a chance, but instead he's rebuilt the English language in a very practical form.

Ray's system gets rid of letters with two sounds, letters which aren't needed, double letters, silent E's, and so on. Sure, it makes sense and would make it infinitely easier to learn to spell.

Continued on page 68

Just Who *Did* Invent Radio?

If you're sure you know, the answer may surprise you.

Glen E. Zook W5UOJ
410 Lawndale Drive
Richardson TX 75080

There's a lot of interesting history in the realm of radio and its child, television. The players include inventors, businessmen, performers, and lots of other people. Unfortunately, the vast majority of this information has not been made available to the masses!

Marconi

First of all, ask the average American, "Who invented radio?" If they know at all, the reply will usually be "Marconi." For most of my life, and that of my parents and grandparents, *the* inventor of radio has been, according to all the history books, Guglielmo Marconi, born in Bologna, Italy, on April 25, 1874. Marconi was the son of a very successful Italian businessman with extensive business ties to Great Britain.

Marconi was interested in wireless telegraphy (radio) from an early age, and conducted experiments on his father's estate starting in June of 1895. Later that year he was able to send messages up to one-and-a-half miles.

Seeing the commercial potential of communications with ships, the 22-year-old Marconi went to England where, in 1896, he was granted his first patent on radio communications. Later, with the help of his father, Marconi contacted a number of influential British businessmen, and the Marconi Company was formed to develop wireless communications. Until about 1920, this company dominated the radio scene worldwide.

Lodge and Fessenden

However, several years before Marconi even started experimenting, as early as 1888, Oliver Lodge (later Sir Oliver), a professor at Liverpool University, was conducting experiments in wireless telegraphy. Lodge was granted a patent on his system (which, by the way, was the source of the receiving detector used by Marconi—the coherer) in May 1897. This patent was purchased by Marconi in 1911.

"*By the mid-1890s Fessenden was transmitting voice and music from the shore to people aboard pleasure boats on the St. Lawrence River.*"

At the same time, a Canadian university professor (Western University) named Reginald Fessenden was experimenting not only with wireless telegraphy, but with voice and music transmission as well. Also, he was interested in the radio control of boats. By the mid-1890s Fessenden was transmitting voice and music from the shore to people aboard pleasure boats on the St. Lawrence River.

Dolbear

As you can easily see, both Lodge and Fessenden predate the experiments of Marconi but they were late-comers, for, in 1886, the United States patent 350,299 had been issued to Amos Dolbear, a physics teacher at Tufts College. In fact, for a time, Dolbear was able to keep the Marconi Company from operating in the United States because of his patent for a wireless telegraphy system (which, by the way, was virtually identical to the system used by Marconi)! Later, the Dolbear patent was purchased by the Marconi Company, thus allowing them to use wireless in the United States.

Loomis

Dolbear was also late on the scene, for, as early as August 15, 1858, an American dentist named Mahlon Loomis was beginning a series of experiments in wireless telegraphy within the state of Ohio! With the interruption of the American Civil War, Loomis continued his work. In October of 1866 he sent signals between two mountaintops, about 15 miles apart, in the Blue Ridge Mountains. Senator Samuel Pomeroy of Kansas and Representative John Bingham of Ohio were present at this demonstration. Both men later gave much support on Loomis' behalf in the U.S. Congress.

In January of 1869, Senator Charles Sumner of Massachusetts introduced a bill into Congress to appropriate $50,000 (well over a million dollars in present-day purchasing power) for development of Loomis' system. This bill languished in committee for two years, at which time Rep. Bingham introduced a bill to incorporate the Loomis Aerial Telegraph Company, giving it the right to issue up to two million dollars worth of stock. This bill stated that no money was to come from the U.S. Government (one of the reasons the original bill was stalled in committee).

In early 1873, President Grant signed the bill into law, and a few months later, on July 20, 1873, Loomis was granted U.S. patent #129,971 for the invention

of his system. Unfortunately, Loomis' company had gone bankrupt during the stock market "panic" of 1869, and he was never able to garner enough financial support to put the system into operation.

Although Loomis died in 1886, he left his mark in other areas. He was not only an inventor in the area of radio, but he also held a number of patents in the field of dentistry, including methods of making false teeth and specialized filling materials and methods. Some of his ideas are still being used today!

Patent disputes

There are certain things to be noted about these early inventors. The first is that during this time period, patent offices would issue patents on working items only, either full-sized or models. Thus, Loomis, Dolbear, and the others had to actually demonstrate that their equipment worked! There was no patenting of ideas at that time.

Next, although most of the people involved were university types, they did not publish papers to the extent that papers are published today. Also, there was a lot of nationalism involved with something of such possible importance as communicating without wires.

Marconi had established a consortium of powerful British investors. Several of these were members of Parliament, and the rest were in a position to command the ear of that governing body. Because of this, both Lodge and Fessenden (Canada being a member of the British Commonwealth) were effectively silenced by governmental actions. The Marconi Company soon dominated the wireless (radio) scene.

From about 1900 until 1943, there were a large number of patent rights battles in the courts of the United States and Great Britain. Little by little, Marconi's patent empire was voided until, just before his death in 1943, his last patent was vacated in favor of Nikola Tesla.

In fact, Marconi's list of patent fights included almost all of the inventors and pioneers of radio communications. People like deForest, Fleming, and others were in an almost constant fight with Marconi and his company. Because of these lengthy patent battles, the British Government did not wish to aid those fighting against the British-based Marconi Company. Therefore, they insisted that Marconi was the inventor of radio. It is unfortunate that this misconception is still being taught today.

Marconi, through the efforts of his British company, did more than anyone else to commercialize radio. However, he really did nothing himself in the actual invention of the systems. Everything he used was invented by someone else, and was actually used in two-way radio communications before Marconi. In Loomis' case, the patent was issued before Marconi was even born!

Because the history books of the early 20th Century taught that Marconi was the inventor of radio, it is still being taught today. This is unfortunate, for there were, in reality, several true inventors (each with a different system type) who were communicating before him. But such is the world of the history text writer.

There are other such tales about grossly wrong history texts, but those can wait for another time!

Repeater Coordination

Boom or bust?

Glen E. Zook W5UOJ
410 Lawndale Drive
Richardson TX 75080

97.205(c) Where the transmissions of a repeater cause harmful interference to another repeater, the two station licensees are equally and fully responsible for resolving the interference unless the operation of one station is recommended by a frequency coordinator and the operation of the other station is not. In that case, the licensee of the non-coordinated repeater has primary responsibility to resolve the interference.

In my copy of Part 47 of the Code of Federal Regulations, that part of federal law which pertains to the Federal Communications Commission (FCC), this is the *only* reference to coordination of amateur repeaters except for the definition of frequency coordinator in Part 97.3 (20). Unless I have overlooked some other reference, and I have read and re-read the regulations many times looking for such, this is the basis on which all frequency coordination bodies within the areas served by the FCC exist.

"When a frequency coordination body gives coordination to an amateur for the purpose of placing a private (or closed) repeater in operation, that body is, in effect, giving ownership of that frequency to a particular amateur, which is in direct violation of federal regulations."

The unfortunate history

When FM and repeaters first came into vogue in the late 1960s, unfortunately, in some areas, there did exist groups of amateur radio guerrillas who waged "wars" over specific frequencies on which they operated their repeaters. Although most repeater operators tried to cooperate with other repeater operators, there were a few hardheads who absolutely refused to cooperate with anyone. Various attempts were made to bring these operators into the fold, including (I am told) nighttime sorties to repeater sites, pins through the coax, and all sorts of damage done to the equipment.

Of course, such activities are illegal under both civil and criminal law, but such were the activities of a few renegades during the battles of the 1960s. Then, when vigilante justice was abandoned, various organizations of amateur radio repeater operation arose. At the time, there were at least three items on their agenda. The first was to serve as a clearing house for technical data. The second was to influence the FCC during times when the actual existence of repeaters was in doubt. The third item was to serve as a coordination body to help alleviate repeater interference on the very few frequencies then being used.

In most areas, the repeater pair was 146.340 MHz input and 146.940 output. In a few areas, 146.940 MHz was reserved for simplex operation, so 146.340 MHz was paired with 146.760 MHz as an output. But, within a very few years the standard frequency splits came into being. There are explanations why the upper 1 MHz of 2 meters has an inverted split, but that will be reserved for another time. With almost every repeater on the same frequency, turf wars were inevitable. However, as the coordination bodies came into being, many existing repeaters, and virtually all new repeaters, were moved to other, approved, frequencies.

Today's problems

In general, for many years, the frequency coordination bodies have done an excellent job of preventing repeater wars. However, a significant number of these bodies have lapsed into a police state mentality when dealing with repeater coordination. They have forgotten that they have no basis in law for their existence. They threaten, they tell lies, and sometimes they give preferential treatment to certain individuals.

In many areas, frequency coordinators will tell an amateur that no frequency pairs are available in certain bands (primarily the 144 MHz and 440 MHz bands), but when one tries to bring up a repeater, nothing happens. Then it's back to the coordinator who then tells the applicant that these are *private* repeaters, and that the frequencies are not available for use by the general amateur public.

Well, I seem to remember that within the regulations of the FCC that no one owns a frequency. All frequencies available to an amateur, within his license class limitations, can be used. The only restriction is not to interfere with an *ongoing* communication. If no one else is using the frequency, then it is perfectly OK to use that frequency. Period! But, when a frequency coordination body gives coordination to an amateur for the purpose of placing a private (or closed) repeater in operation, that body is, in

effect, giving ownership of that frequency to a particular amateur. This is a direct violation of federal regulations.

For example, in California, according to a fairly recent edition of the *ARRL Repeater Directory,* there are 426 repeater stations in the 440 MHz band located in the northern portion of the state. Of these, 170 are open, and the remaining 256 are closed. This makes a total of almost exactly 60% of the repeaters in the northern portions of California closed. In the southern half of the state there are 452 repeaters listed, of which 38 are open. That makes a whopping 84% of the 440 MHz repeaters in southern California *closed!* Yet, each and every one of these repeaters is presently protected from interference from normal amateur operation.

Is this fair? In my opinion, no way! Is this trend all over the country? You bet your sweet bippy! Is this legal? *No way!* But such are the activities of the majority of frequency coordination bodies in the United States.

Now, I have no problem with closed or private repeaters. The FCC has issued opinions that a repeater operator can restrict the users of his/her repeater. Often, these repeaters are just an excuse for a private phone patch (autopatch) for use by a single, or at most a few, amateurs. Legal? As long as the conversations fall within FCC guidelines; but should the amateur community in general suffer the loss of the vast majority of frequency spectrum to support the whims of a very few amateurs? I think not!

Possible solutions

I propose two possible solutions. The first is to designate a few frequency pairs for use by private or closed repeaters. Since each probably has only a few users, there will be little chance for interference. Often, and I have monitored some of the closed repeater frequencies for quite a while, there is no activity for days, even weeks! Yet the frequency pair is coordinated and thus unavailable to the general amateur public.

The other solution is to continue to coordinate private repeaters and/or allow them to operate on the frequency pairs now allotted. But, when an amateur, or group of amateurs, wants to install an open repeater, the frequency coordination would automatically be revoked and be transferred to the open repeater. In areas in which there are frequencies available, it may take years until the frequency coordination of a closed repeater is revoked. On the other hand, in areas where no frequencies are available, then frequency coordinations might start to be revoked immediately. However, a repeater open to *all* amateur operators should take priority over one with restricted usage.

"A repeater open to all amateur operators should take priority over one with restricted usage."

Amateurs who are now operating closed or private repeaters will not like giving up their exclusive rights to a frequency. But, since this ownership of the frequency is illegal under present regulations, they have no right to this de facto ownership. I cannot blame someone for wanting to have his/her private frequency, but such activities are prohibited by law. Thus, much of the blame must go to the coordination bodies who have allowed and even encouraged this practice for so many years.

Of course, there are amateurs who have gotten frequency coordination for a repeater and who have never placed a machine on the air. Definite time limits should be set (say three months) for a repeater to be placed in operation. If there are very extenuating circumstances, a one-time extension of another three months could be given. Then, no matter what, the frequency goes back into the coordination pool if no repeater is in operation.

Many amateurs are intimidated by frequency coordinators. Unfortunately, some of these people have declared themselves to be demigods, and refuse to face the reality of amateur operations today. It is possible to force the frequency coordinators back into the real world—it just takes a concerted effort on the part of the majority of amateurs.

Anyway, in the urban areas of the country there are just not enough frequency pairs to go around if we continue to allow all the private and closed repeaters to operate with no restrictions. According to FCC regulations, no person can own a frequency. Thus, the practice of allotting our scarce frequency spectrum to a very small number of amateur radio operators must not continue. However, unless a cry is heard from the majority of operators, this will continue to happen, as it does now.

Cry out! Let the ARRL, your state repeater organization, your local frequency coordinator, the editors of any club newsletters you know, and anyone else who can help know of your displeasure with this practice of coordinating closed repeaters to the detriment of normal amateur operation. Yes, there is a place for closed repeaters, but not at the expense of general amateur operations. Think about it, then act.

The 2m Quad Project

Here's a great antenna project for your club!

Larry R. Luchi W7KZE
P.O. Box 1612
Mukilteo WA 98275

As the rainy season blew into Puget Sound, I was giving thought to the second semester of our electronics technology program at Sno-Isle Skills Center. During this semester I teach amateur radio to my junior and senior high school students ... a daily block of three hours of classroom lecture and lab. Each of my students builds an AM/FM superheterodyne receiver to give further understanding to my lectures on electronics theory. This gives these teenage intellects a break from the 30 minutes of dits and dahs of Mr. Morse's code.

December brought rain, rain and, when the sun was about to appear, more rain. January was just a little bit more of December: rain, rain and wind. What does this have to do with young high school students and amateur radio? A reason to demonstrate antenna theory in the classroom, and hope for sun in February—to be exact, on Groundhog Day. On February 2nd the sun did peek out to greet my birthday. Having spent over nine-tenths of my life as a ham radio operator, I felt that this was an appropriate time to take the class outside to test the antennas we'd made in the classroom.

"The rationale for using oxyacetylene welding wire for the elements was to keep the cost of our quad to $0, and also to improve the students' soldering skills."

We'd made a half-wave dipole for 2 meters, 146.58 MHz, using the formula 468 divided by the frequency in MHz for a length of 38.5 inches. Devin Corbett KB7NKT cut the number 12 wire and installed a PIN diode and a Fluke 87 Digital Multimeter in series with the antenna to measure the current. Two meters gave us the compact size and also allowed me to demonstrate vertical and horizontal polarization.

Photo A. Devin Corbett KB7NKT and Matt Chapsin checking the SWR.

As I explained the half-wave dipole antenna to my students, their eyes began to glaze: "Like how can this work?" With our demonstration, some of these bright young minds opened up and started to ask questions: "How can a full wave fit into a half-wave length of wire?" My excitement increased with each question. I found *The ARRL Antenna Book* and started to look for a 2 meter quad antenna that we could make with little cost to the students.

Sno-Isle Skills Center is a vocational high school with 22 programs of instruction, from automotive technology to welding. The resources of the faculty and supplies are a ham's dream come true.

During the last week of January, it rained some more. This was an opportune time to build a single-element quad at home to illustrate a full-wave antenna to the students. The third quarter of instruction is communication electronics and the goal of each student is to pass the Technician Plus exam. The half-wave dipole and quad are both antennas that are covered in the exams. In my lectures on antennas the students calculated the length of each type of antenna needed to pass the exams. For quads, the length of the full-wave loop can be calculated by 1005 divided by the frequency in MHz. If multiple elements are used, the reflector should be five percent

longer and the director(s) five percent shorter.

With my *Antenna Book* in hand, I went to the faculty lounge to discuss my quad antenna project with some of the staff. I showed Dan Minzel, our welding instructor, the drawings of a portable 144 MHz four-element quad. He had a large quantity of 1/8-inch diameter oxyacetylene welding wire that we could use for the loops. Al Urness N7QDC, our plastics instructor, had the PVC support (spreaders) and a Fiberglas™ boom. The machine trades instructor, Tom Clemans, suggested he have his students drill all of the holes needed in the PVC (spreaders) supports and boom. It's as exciting to have cooperative working groups on the staff as it is to teach in the classroom. It was a good beginning to the second semester.

"The resources of the faculty and supplies at Sno-Isle Skills Center, a vocational high school, are a ham's dream come true."

The element spacing for quad antennas found in literature ranges from 0.14 to 0.25. Factors such as the number of elements in the array and the parameters to be optimized (F/B ratio, forward gain bandwidth, etc.) determine the optimum element spacing within this range. The four-element quad we constructed in class was cut for 146.58 kHz. We decided on a reflector length of 86 inches, with the driven element 81 inches and the directors 77 inches long.

Construction

We began with the 10 feet of 1/2-inch PVC for the booms that was provided by Al. It was cut to 42 inches in length, with allowances given for the two PVC tees, one for the reflector and one for the first director.

The reflector tee was glued to one end of the boom, 16 inches from the center of the driven element tee. This was the work of another classroom team led by Matt Watson. Matt made sure that the distance from the center of the reflector tee was 16 inches to the center of the driven element tee, and the second director tee was on center, 13 inches from the driven element. Finally, the first director measured 13 inches from the second, then all of the PVC tees were glued into place.

Construction of our first four-element quad began with 1/2-inch PVC spreaders. These elements were first assembled with the holes drilled for the 1/8-inch brazing rods. The reflector spreader was 22-1/2 inches long, with 1/8-inch holes drilled 10-3/4 inches from the center of the boom. The driven spreader was 21-1/4 inches long, with holes drilled 10-1/8 inches from the center of the boom, and the directors were 20-1/4 inches, with holes drilled 9-5/8 inches from the center of the boom.

We used 1/2-inch PVC for the boom with PVC tees to install the spreaders; each spreader was cut in half, i.e. the reflector was cut at 11-1/4 inches, then each end was glued to the tee and in turn to the boom.

The rationale for using oxyacetylene welding wire for the elements was to keep the cost of our quad to $0, and also to improve the students' soldering skills. No. 8 aluminum ground wire will work just as well. The brazing rods cost around $2.26.

A 12-inch x 2-inch Plexiglas™ plate was used to support the feed point hardware and the feedline. The feed point support was epoxied to the boom. Using a heat gun, we bent the Plexiglas to meet the driven element. The ends of the brazing rods were 3/4 inch apart where they mounted on the Plexiglas plate. We left enough excess rod to bend a small loop for attachment to the coaxial feedline with stainless steel hardware.

For vertical polarization, we located the feed point in the center of one side of the driven element. In tests, we found that there was a 10 dB loss in the horizontal polarization when we tested with a local repeater.

We connected the coax to the bolts connected on the driven element support plate, and ran the RG-8 along the Plexiglas to the boom. From there the cable was routed directly to the mast and down. The antenna provided very good performance, with a reasonable SWR over the entire 144 MHz band. We used a Bird wattmeter to measure the reflected power and found that with 100 watts out, less than 1/2 watt was reflected.

The kids now know what a full-wave antenna is, compared to a half-wave antenna. Our next classroom project is to build a PVC 10 meter quad. We'll be looking for you on 10 meters.

Photo B. Devin Corbett KB7NKT measuring the spacing for the feedline.

Life After Your No-Code Tech License and Handheld

Without having to know CW.

Michael Farrar VE3WMF
12-125 Weldrick Rd W.
Richmond Hill ON L4C 3V2
farrarmi@epo.gov.on.ca

Now that you have your No-Code Technician's license, you've bought a 2m handheld, mounted it in your car for mobile use, even put up a good vertical antenna on your chimney, and bought or built a 13.8V power supply to get the handie's "full gallon" out ... *great, welcome to the hobby!* Now where do you go from here? There are several modes, other than FM repeaters, that will let you talk to a wider world.

With repeaters, you can get out a reasonable distance, but with a better antenna and more power (30-150+ watts) you can do even better on the FM simplex frequencies. Add a linear amplifier (with a receive preamp) to your handheld and a modest beam antenna mounted 10 feet or more above your roof line, and you are in business. Contacts up to 100 miles are routine (including distant repeaters), but when the band opens up, look out! Contacts of up to 500 miles are common. All of this assumes you do not live in a hole; if you live in a valley with a 100-foot+ ridge within a quarter mile, you should consider moving, learning CW and going HF, or going to satellite operation.

> ***"Welcome to the hobby! Now where do you go from here?"***

Vertically polarized FM signals do not travel as well as horizontally polarized SSB signals. This world requires multimode transceivers, which are more expensive because they do everything your handheld will do, but add SSB and CW modes, more power, and more features. There is a lot of activity in both modes on the 2 and 6 meter bands, with a bit less on 70 cm. Let's stick with 2 meters for now because you will likely want to use FM to check into nets and use repeaters—so keep your vertical antenna.

Transceivers

What is available? Unfortunately, not much on the used market. Rigs occasionally become available, but sell quickly. Most older rigs seem to have been good, but avoid radios that are more than eight years old if you want to work satellite (they aren't designed for the required talking and tuning). In the current market, the basic multimode is the Yaesu FT-290RII. It puts out 25 watts, is small, and can be used as a base, mobile or fat handheld. The new Kenwood TM-255 can be either a mobile or base, puts out 40 watts, has many more features, and costs more—but it's worth the extra money. Both these rigs can be enhanced with a linear amplifier that will boost the output to 150-170 watts. It is best to get one with a GaAsFET receive preamp for weaker signals. They cost about $280 and require a minimum of a 35 amp power supply. Next, there is the ICOM IC-275H base station running 100 watts. It requires a 12V, 20A power supply. The IC-275H costs more than the Yaesu and Kenwood models, but it is required if you want to drive a full-legal-limit linear. Finally, there are multiband base stations that start at $1,700 and go up as you add bands and options. The extra investment may be worth it if you want to work 2 meters and 70 cm or 1.2G (one radio will do four bands) and all satellite modes.

Towers, antennas, and feedlines

It helps to have a good antenna, but it helps even more to get it up as high as you can and feed it with the best coax you can afford. Since VHF antennas are small and light, TV towers or mounts are more than adequate. Used TV towers are relatively cheap and easy to install. If you live in a two- or three-story house with a high-pitched roof on high ground, then a rooftop tripod mount will do just as well.

Use RG-8 or better coax for runs up to 50 feet, and RG-9913 or 9914 for longer runs. Hard-line or heliax is ideal if you can get it cheaply, but be careful to examine used hard-line very carefully for any previous kinks or water penetration.

You will need a rotor and, again, a TV rotor is all you need. Used ones are all right but I prefer new ones with good seals to prevent freeze-up if you experience that type of weather.

If you enjoy building things, then it is easy to build your own antenna. The simplest antenna is a cubical quad, but feed the coax at the bottom for SSB and at the side for FM. This antenna can be made from common building materials such as wood, ABS, PVC, CPVC, aluminum wire, copper wire, or brazing rod. Plans are readily available and easily adaptable to the materials you are comfortable working with. Just be sure you build it well; most plans I've seen are rather flimsy designs that are not suited to Canadian or Minnesota winters. If you got a used TV antenna with your used tower, or you otherwise find used TV/FM antennas, they are an excellent source of material for a yagi antenna (*73*, September 1993). To improve gain, stack two yagi antennas for an extra 3 dB. To achieve the same increase in gain you have to double the boom length, which creates major mechanical and wind load

problems. A VHF SWR meter (MFJ-812B or equivalent costs about $30) is a must-have to tune your antenna.

If you are not a builder, an eight- to 13-element commercial yagi will work just as well. Get one that is optimized for the 144-146 MHz part of the band (that's where the SSB/CW activity is).

RS-10 and RS-15

These are Russian amateur satellites that are relatively easy to use because they are in low circular orbits. If you started as an SWL and have a good tabletop communications receiver that handles SSB, then you are in business. You will also need a computer and some tracking software to tell you when the satellites are overhead. These satellites receive SSB or CW on 2 meters, then return the signals on the 10 meter band; look at them as a fast-moving repeater in the sky, with a big offset. You should listen to them on 29.352-29.405 MHz USB first because you may be in a high-noise area and because they are low power; local noise levels may overpower their signal.

A homemade quarter-wave vertical or turnstile 2 meter antenna (25-100W) and a 10 meter inverted Vee antenna with a 10 meter preamp both work great. With the satellite in the right position you can talk to all four coasts. The newer RS-15 satellite is in a higher orbit with even better coverage (into western Europe and northwest Africa from eastern N.A. and Central/South America). If you do not have a good SW receiver, used Radio Shack™ HTX-100 10 meter transceivers sell for $100-125 (or less if it has a blown transmitter). For an additional investment of $30-200 you can cover three continents and Hawaii.

Other birds

There are a number of other amateur satellites available that are in higher elliptical orbits. They also have a different set of transponders, operating in the 144 and 430 MHz bands. Because of their higher orbits they have much better coverage (sometimes halfway around the world). To work them requires a dual-band multimode transceiver and a special antenna and rotor system for tracking.

"If you have a big back yard, very understanding neighbors, very deep pockets, and considerable technical skills, then bouncing signals off the moon can be a real challenge."

6 meters

Depending on conditions, this band can be either a VHF band or an HF band without much of the noise associated with HF. Contacts of 250 miles are routine, but when this band opens up it is spectacular. Contacts into Central and South America, and occasionally Europe, are possible. Since 6 meter antennas are larger, TV towers become marginal unless they are well guyed. Likewise, TV rotors are not adequate for larger (four- to six-element) boom antennas: medium duty rotors are recommended, or required if you add your 2 meter beam to the mast.

Moonbounce

If you have a big back yard, understanding neighbors, very deep pockets, and considerable technical skills, then bouncing signals off the moon can be a real challenge. Eight 17-element yagis, a precise two-axis rotor system, a computer to control it, a full-legal-limit linear, a super-low-noise preamp, and a good transceiver are all you need. It would also help to be single or have a wife who is a ham and shares this interest. With this mode, I have violated the subtitle of this article—moonbounce activity is almost entirely CW, but 5 wpm is enough.

Survey of VHF/UHF Radios

The following list is by no means comprehensive but is intended as a beginner's guide to the marketplace. Detailed specifications can be obtained from the manufacturers or your favorite ham radio emporium. Prices quoted are from my favorite U.S. discount chain. Your dealer may sell for less but ask them why if they do not.

Single-Band Multimode Radios:

- Yaesu FT-290RII 2 meter mobile—$630; 25W. Basic FM radio with SSB/CW added, few features and not suited for satellite or CW operation.
- Kenwood TM-255 2 meter base/mobile—$900; 40W. Full-featured "state-of-the-art" FM/SSB/CW transceiver.
- ICOM IC-275H 2 meter base—$1,700; 100W. Full-featured FM/SSB/CW transceiver, recently reduced in price.
- Kenwood TS-60S 6 meter base/mobile—$990; 90W. If you want to go 6 meters, this is the radio.
- MFJ-9406X 6M SSB/CW base—$260; 10W. Excellent starter radio; add a linear as budget allows.

Used 2 Meter Radios:

- Kenwood TR-751A—A not-so-old goodie. They sell quickly; be first in line at the hamfests. $400-600.
- Kenwood TR-9000—An oldie, but perhaps not so good any more. 10W (or 30W on TR-9130). Unsuitable for satellite operation. Good starter radio for about $200, or $250 for the 9130.

Multiband (2 Meter and 70 cm) Radios:

- ICOM IC-820H—ICOM's newest, but 2 meter and 70 cm only. $1,700; 30W-45W. Full-featured for terrestrial and satellite.
- ICOM IC-970H—ICOM's best. $3,900; 30W-45W; 1.2 GHz optional. Overpriced compared to others.
- Kenwood TS-790A—$1,770, 30-45W; 1.2 GHz optional.
- Yaesu FT-736R—$1,830; 25W. Can add two more bands from 50 MHz to 1.2 GHz for great flexibility.

Amplifiers:

Any radio with less than 50W should have a matching linear amplifier. Manufacturers are: Henry or Command Technologies for kilowatt units, and Mirage, RF Concepts, RF Technologies and TE Systems for 100W-300W units.

QRP

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Operating QRP usually means you're going to be using CW. Building a transmitter for CW is a lot easier than hacking one out for SSB. So, it's easy to see why there are many add-on devices to improve the sending of CW, but there's very little on the market for the phone operator. Voice memory keyers have been expensive for the once-in-awhile QRP phone operator—until now.

"Voice memory keyers have been expensive for the once-in-awhile QRP phone operator—until now."

The ChipCorder

Killing some time at a local Radio Shack™ store, I came upon a small blister package containing the VM-1110A voice record and playback module. The VM-1110A is a self-contained solid–state voice module that will hold up to 10 seconds of audio. The entire VM-1110A is housed on a preassembled PC board about the size of a postage stamp (see **Photo A**). There are about a dozen surface mount components on the board, while the actual ChipCorder is just a blob of epoxy on the circuit board.

The circuit board is fitted to go inside an edge-card connector, or to be plugged into the PC board with the supplied dual-pin header.

A closer look

The VM-1110A contains everything you need to record and play back audio. All you need to add are some switches and an electret microphone. The VM-1110A has a built-in audio preamplifier, automatic gain control, and an anti-aliasing filter on board. There's even an audio power amplifier on the board that will drive a speaker directly. But perhaps the best part of the VM-1110A is the price—it's only $15! The Radio Shack stock number is 276-1324.

Another feature of the VM-1110A is the automatic power-down mode to drop current to .5 µA. It will operate on a single +5 volt supply, and the message storage retention uses zero power. After I've been laid out on that cold marble slab, the VM-1110A will still keep my "CQ CQ QRP..." in memory for at least 100 years!

Making the VM-1110A talk

You'll need a +5 volt supply at 35 mA to run the VM-1110A. A 78L05 will work, just be sure you bypass the input and output leads of this regulator with some .1 capacitors.

You can also use a set of four AA batteries with an 1N4002 diode in series to drop the voltage down to .5 volts. If you use the batteries, there is no need to use the regulator. Be careful to put the correct polarity to the VM-1110A as it will most certainly be damaged by reverse voltage polarity.

You'll also need an electret microphone; Radio Shack #270-090 is the one of choice. Also, a couple of push–button switches will be required for the start/record and playback function.

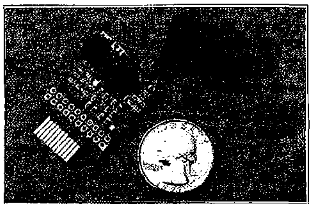

Photo A. The entire VM–1110A is housed on a preassembled PC board about the size of a postage stamp.

There's not much to do—you hook up the switches to the correct pins and connect the microphone, apply power, then begin recording. You can make up to a single 10-second recording. At first that does not sound like a lot of run time, but in real life, 10 seconds is rather long! Most dyed-in-the-wool DXers can work six contacts within a 10-second period.

Recording

To record a message, a low-going transition on the REC line initiates a new record operation from the beginning of the memory, or at a selected location, regardless of any current operation in progress. You do not need to fill the entire memory. Releasing the REC signal HIGH before filling the message spaces causes the recording to stop and an "end of message marker" to be placed. The device then powers down and goes to sleep.

You can place an LED on the RECLED output pin to provide an active low signal which can be used to drive the LED as a "record in progress" indicator. The module has a 1k current-limiting resistor already on the board to limit current to the LED.

Playback

Pulling PLAYE or PLAYL signal LOW initiates a playback cycle. This cycle is then completed when the end of message marker is encountered. Playback then ceases and the device goes to sleep.

Interfacing the VM-1110A into the rig

I coupled some of the audio output from the VM-1110A directly into the microphone jack of my Argonaut II. It seemed to work just fine after I played with the gain and drive controls.

A much better approach would be to use an op amp as a simple microphone mixer and adjust the mixer to match the audio level of the external microphone. This way, the audio level from either the VM-1110A or the microphone would be the same.

Odds and ends

I guess it would be possible to use one of the level active pins and link two or more VM-1110A modules together to provide longer record and playback times. Any one want to give that a try?

As a club project, a single circuit board could be assembled to hold a VM-1110A and the required switches and power supply. You could record and then remove the VM-1110A to use at a remote location.

"For the ultimate bell and whistle, how about a programmed VM-1110A triggered by an SWR sensor to alert you to a problem with your antenna system?"

The VM-1110A is cheap enough to allow you to record one module with a CQ and then a second or third module to hold reports or "QRZs..."

And for the ultimate bell and whistle, how about a programmed VM-1110A triggered by an SWR sensor to alert you to a problem with your antenna system?

All in all, the VM-1110A is a whale of a lot of fun. There's not much in life that's this much fun (legally, anyway) for under twenty bucks. Pick up one of the VM-1110As from Radio Shack and shoot a Saturday evening.

He rides the airwaves

Now that I'm in the process of packing away many of my wall displays of QSL cards and trying to fit the school term's collection of papers and books into cartons for the summer, I promise myself to throw away outdated materials that I can no longer use. Being a collector by nature, this is no easy task. I subscribe to the philosophy of "sooner or later every scrap will have some use."

Since I am rapidly growing out of classroom space and storage area, I must start separating my materials before I pack them away. One textbook that definitely goes into the "to save" pile is *Ride The Airwaves With Alpha & Zulu*, written by John Abbott K6YB. If you're looking for a new resource to put into your classroom or clubhouse library, you should consider this book.

John Abbott K6YB

First, let me tell you a little about John. His class and mine made several really terrific radio contacts a few years ago. He has been teaching ham radio class, a requirement for gifted students at Los Feliz Elementary School in Hollywood, California, since January 1990. Then a communications engineer for the Los Angeles City Department of Water and Power, he had joined a DWP program in which engineers did volunteer work with students one day a week. He chose Los Feliz Elementary at the suggestion of his wife, Teri, who teaches third and fourth grades there.

He retired in 1992 and now holds classes twice a week. "My wife told me the kids needed something like this as an outlet," says John, a ham radio devotee since he was 13. "Most of the kids live in little apartments. This lets them know there's another side of life out there."

According to a newspaper article John sent me, his students have spoken with people in Mexico, Central and South America, and as far away as New Zealand and Japan. They communicated with the space shuttle in 1993 and received printouts from NASA's MARS observation satellite observing Mars.

School principal Betty Castaneda estimates that John's contributions would cost the Los Angeles Unified School District about $30,000 a year if he were paid. That's not even mentioning the equipment he's donated—about $5,000 worth. She says, "There are four or five other schools in our district that have a ham radio class, but they don't have a real engineer to teach them, and they're not as diversified.

"The most important thing John does is provide a role model," she says. "He's comfortable around the technology, so the kids are too. Also, more than half the kids do not have fathers—they come from single-parent homes—so he's a father role model as well."

As for the kids: "It's fun," says 10-year-old Gerardo Arturo Estrada. "You get to meet a lot of people and make friends."

John sees another appeal, the one that hooked him as a teenager: "Here you are in your little world, and all of a sudden you can get on the air and talk to anybody in the world," he says. "It's that feeling that you're riding the airwaves. You're bouncing around the world; your voice is going through space and time forever."

"School principal Betty Castaneda estimates that John's contributions would cost the Los Angeles Unified School District about $30,000 a year if he were paid, and that doesn't even include the equipment he's donated—about $5,000 worth."

The newest *Ride The Airwaves*

The 1996 edition of *Ride The Airwaves With Alpha & Zulu* is an improvement over the 1993 version. There are now 59 characters instead of 16—all 43 characters required by the Element 1A code test, plus 16 binary characters. In addition, a "space" theme has been incorporated. This delightful soft-cover book uses comic book characters, The "Phoneticos," to prepare students to take two different amateur radio exams, the Novice and the No-Code Tech. If you look closely at the Phonetico characters you will notice that each of their bodies is made up of the Morse code "Dits" and "Dahs" that form the correct symbol for that character's letter.

After each cartoon page there is a testing page. The answers to the quiz are found on the bottom of the following page. There are crossword puzzles and games throughout the book. The children in my sixth-, seventh-, and eighth-grade ham radio classes always enjoy the lessons I do based on material from John Abbott's book. For more information or to purchase a copy of the book (single copy: $14.95), contact John at ABTRONIX, P.O. Box 220066, Newhall CA 91322, (805) 222-7384.

Well, there's no need to continue the throwing out process today. I'll pick up where I left off tomorrow. Of course, if I keep on discovering books like John's that I enjoy so much, not too many items will be thrown away. What I really need is a suite of rooms, not just a classroom, for all my wonderful ham radio materials. Have a great summer!

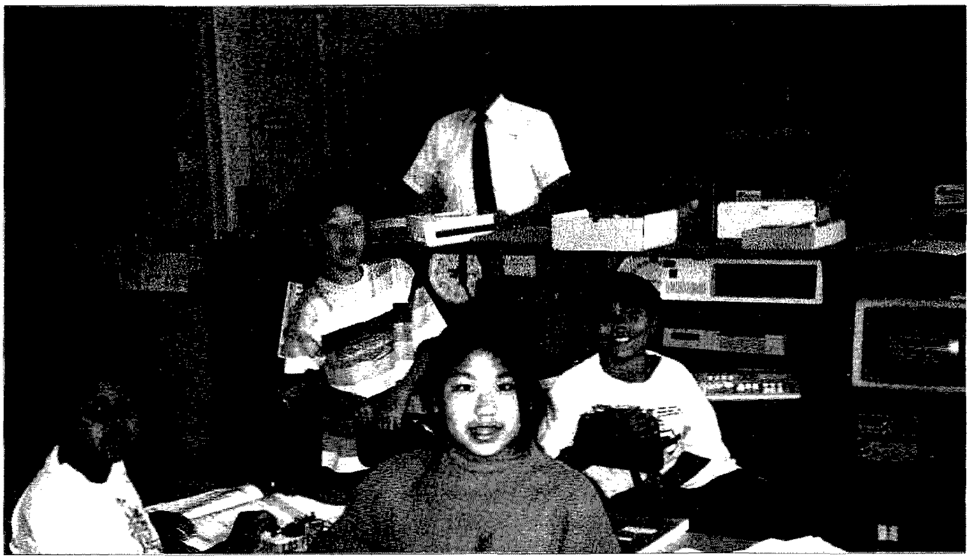

Photo A. John Abbott K6YB (rear) with Joyin and Jimmy (back row), and Gerry and Suzan (front row). Joyin is from Korea, Jimmy and Suzan are from Thailand and Gerry is from Mexico.

Ham to ham

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

This month's column contains quite a bit of good information, so let's get right to it. Suffice it to say that I'm always interested in any ideas from readers, such as the ones below, that have practical amateur radio applications. So get out your pens, word processors or parchment and quills, and keep them coming this way. My address is at the top of this page. All contributions will be promptly acknowledged; I'm also usually able to give you a rough idea of when your tip will appear if it's accepted.

On the "light"er side

In last month's column, I suggested using one of the new "laser pointers,"for "seeing-through" a printed circuit board so that a component located on the top side of the board could be easily identified for unsoldering on the bottom side.

In addition to the laser pointer, a small Mini-Mag® light, one with a beam that's able to be focused down to a small "spot," can be used to highlight the area of interest. It's not as dead-on-accurate as a laser pointer, and it only works on PC boards that are translucent—the room must be fairly dark—but it does work nicely on most phenolic boards encountered in ham radio equipment. Sometimes you can even see the silk-screened printing from the other side coming through, though of course it's reversed.

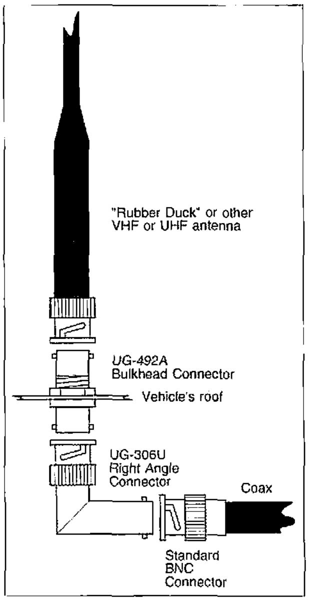

Fig. 1. NZ9E's tip for inexpensively mounting a VHF or UHF mobile antenna on a vehicle's roof.

So if a laser pointer is still not on your workbench (they're down to less than $30 now), a small mag flashlight should be, and it can be used in a similar way. Now all you need do is to hunt down the component that needs replacing! Some of the other tips we have this month may help in that area.

Put the heat on 'em!

To make the removal of self-adhesive labels or escutcheon plates on equipment much easier, try using a heat gun to pre-soften the sticky adhesive backing first. I recently wanted to repaint the top and bottom covers of a used ham transceiver I'd bought. Using a shrink-tubing heat gun to soften the backing on the covers' labels allowed me to neatly remove them without a trace of damage, something that would not have been the case had I tried to remove them "cold." The heat supplied by the shrink-tubing heat gun (or perhaps a directable hair blow dryer) was just enough to loosen the backing so I could slip a single-edge razor blade under the escutcheon label and pry it up. (To reinstall the escutcheon labels after painting the covers, I used Scotch™ #136 Double Stick Tape; it's available at stationery supply stores.) Just be very careful about how much heat is applied to plastic or other surfaces that may be damaged by too much of a good thing. Generally, if the right amount of heat is used, self-adhesive labels will release easily, and can be removed without leaving a gummy residue behind—or at least leave only a minimal amount. Give it a try.

Goo Gone

If my tip on softening labels with a heat gun (above) comes too late, the goo left behind by unsuccessful prior removal can often be cleaned up with a product called Goo Gone®! Really, that's its name! Actually, I have to respect products that state what they do right up front. Goo Gone is made by Magic American Corp. of Cleveland, Ohio 44122. Its maker claims that it's effective in removing residue left behind by tape and other adhesives, as well as oil, gum, tar, scuff marks, polish, wax, grease and many other remnants. It has a pleasant citrus smell and comes as a thin, gold-colored liquid in several container sizes. It can usually be found in hardware stores and home centers. I bought mine at a railroad hobby show, since it's also popular for cleaning model railroad engines and track.

As with any cleaning product, always test a small spot first to check for any adverse chemical reactions, especially on painted surfaces and plastics. There are so many chemical formulations today that it's virtually impossible to make an effective cleaner totally compatible with all of the possible synthetic combinations.

Easy does it!

Here's an idea that I've used several times to give me an inexpensive, option-filled mounting scheme for mobile antennas on my own cars (see **Fig. 1**). It lets me swap antennas at will, as well as remove the radiating element very quickly for automatic car washes, etc., replacing it with a BNC dummy plug instead.

The idea requires drilling a single hole, large enough to pass the mounting threads of the UG-492A bulkhead connector, so if drilling a hole in your car's roof or trunk lid is completely out of the question, read no further. Personally, I'm not averse to the idea since it provides a low-profile mounting arrangement, with a good connection to the surrounding ground plane (the car's metal roof).

The quick exchange of antennas is also very nice, allowing me to use anything from a 2 meter rubber ducky to a 19" whip mounted in a BNC connector, to a 5/8-wave-gain whip antenna...all with a twist of the wrist! Though I've only used this combination on 2 meters, it should work equally well on 1-1/4 meters and 70 cm. It's as strong as the roof of your car, so even a fairly robust 2 meter gain antenna is usable with it. If, however, too much roof flexing occurs, a steel backup plate with a clearance hole drilled in its center should solve the problem easily. When it comes time to sell the car, you can simply leave the BNC bulkhead connector jutting out, or use a small hole-plug to make it even less objectionable...but that's probably the least of the items that the buyer will be concerned about when it comes to your car's value.

Be sure that whatever brand of rubber ducky you use will handle the power output of your mobile radio. Some of these flexible rubber-coated antennas are only rated for a few watts and will become noticeably warm to the touch when any more power than that is applied to them. It's easy enough to test—just place your palm around the antenna's body after 30 seconds or so of FM transmit time; if it feels too warm, use lower power or a different antenna.

Color-wise

From William Thim, Jr. N1QVQ: If anyone is planning on home-brewing an outdoor antenna, and those plans include the use of PVC non-conductive pipe, here's a caveat. Although you may feel that white PVC piping may be better for aesthetic reasons, white may not be the best choice for longevity. White PVC out-of-doors will yellow, lose its plasticizer, become brittle and eventually crack upon prolonged exposure to the elements and ultraviolet rays. So for most amateur antenna work, black is probably the better choice.

Black PVC pipe is embedded with carbon and holds up outside considerably better than its white counterpart. There is also a clear PVC pipe not generally available

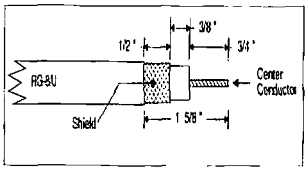

Fig. 2. Stripping dimensions for an RG-8/U cable, using the method of attachment described in WB9YBM's text.

to the public, but it's impossible to guess how the clear variety will weather until it's been in general use for a while. Perhaps other readers may be able to offer more input.

I've used a couple of sections of the white variety of PVC pipe outside on my own antennas, though I don't have any long-term experience with its durability. Bill's point is a good one, and I did paint the pieces I'm using, for the very reason he gave: ultraviolet exposure protection. Painting should help. The black PVC pipe Bill mentioned doesn't seem to be found as easily in home centers in this area of the country, so my use of painted white was pretty much forced upon me. Lacquer spray and oil-based paints seem to hold a bit better to the non-porous PVC surface. Latex appears to be the worst for good adhesion properties on this material, although it does "give" more with any pipe flexing.

Neatness counts

From Klaus Wolter N8NXF: Teflon™-insulated wire is great for repairing damaged foil traces on the bottoms of printed circuit boards, as well as for point-to-point bus wiring, due to its non-melting characteristics, even when subjected to direct contact with a hot soldering iron. Unfortunately, it's not at all easy to strip, especially in cramped quarters! As a result, I've been making my own Teflon bus wires using #24 tinned solid copper wire and hollow Teflon tubing.

I cut off a piece of bus wire a little longer than I think I'll be needing, then stretch it to get it nice and straight by pulling it through my fingers a couple of times. After straightening it, I slip on a length of Teflon tubing—also a bit longer than I think I'll need—and solder one end of the wire to the first connection point. Now, laying out the wire/tubing combination along the path I want the bus wire to take, I slip the tubing right up to the soldered connection point and grip it firmly with diagonal cutters at the other end, where it will end. I then slide the tubing back out past the end of the wire a bit and clip it off. When it's pushed back on again, it will be a perfect fit and the free wire end can now be cut and soldered in place. No tugging, no stripping woes, and it's immune to any molten solder drops and hot irons.

Here's another quick tip you might try if you don't have any lacing cord or cable ties handy: Waxed dental floss makes a tough, space-saving lacing twine substitute to hold groupings of wires together in today's compact radios. You do have dental floss, don't you?

Clamp down on PL-259s

From Klaus Spies WB9YBM: Adapters are readily available for attaching RG-58 and RG-59 diameters of coaxial cabling to a PL-259 connector, but there is nothing similar for attaching the thicker RG-8 diameter cables to that fitting.

Most references suggest that you solder the shield of the RG-8/U coax to the body of the PL-259 (through those little holes on the connector's body, just past the outer shell mating threads), but that requires a great deal of heat and carries with it the possibility of damaging the insulation because of that excessive heating. Well, here's a way to attach RG-8 diameter cables to a PL-259 securely without having to apply any heat at all to the coax's shield conductor, and it makes a reliable,

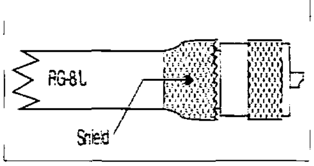

Fig. 3. The shield of the RG-8/U cable is shown fanned in place over the connector's rear sleeve area. See text for complete details.

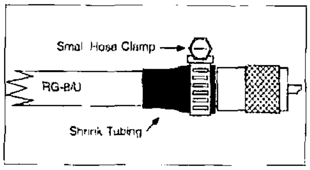

Fig. 4. WB9YBM's completed termination, shown with the stainless steel hose clamp in place over the connector's rear sleeve area.

weather resistant connection in the process.

Fig. 2 shows the stripping dimensions to prepare the RG-8 cable for attachment. Prior to stripping the cable, slip a piece of 5/8" inside diameter heat-shrink tubing and a small stainless steel hose clamp onto the cable's end. Tin the center conductor, screw the outer shell and body of the connector together, slip it onto the cable, then solder the inner conductor securely. Next, fan the shield forward over the rear sleeve area of the body, as shown in **Fig. 3.** Now slip the shrink tubing forward over the fanned-out shield wires, and shrink it down nice and tightly using a hot air gun. The process is completed by sliding the stainless steel hose clamp up and over the tubing and the rear sleeve area of the connector and tightening it down securely, as depicted in **Fig. 4.** I've used a Tridon™ 300-SS clamp successfully, which is about 5/8" inside diameter when fully loosened (but not quite parted). These and other brands of clamps are readily available at automotive supply or general hardware stores. Bring a PL-259 connector along with you if you're not sure of the exact size needed.

That's it; you're done. You now have a mechanically tight, electrically sound PL-259 on a length of RG-8/U or similar diameter cable. For use outdoors, you must still waterproof the entire fitting using layered electrical tape, self-bonding tape, coax cable sealant putty, or whatever method of total sealing you prefer. Water should never be allowed to enter into the coax cable's shielding; this method of attachment helps to assure that this won't happen because of the shrink tubing addition. Should you ever want to salvage the connector in the future, the fact that the shield and surrounding insulation isn't "melted" into the inside of the PL-259 body will make reuse a snap. As far as the soundness of the shield's contact with the connector's body is concerned, I've not had one of these fail me—inside or outside—in a number of years of use. After all, the shield isn't soldered to the mating SO-239 connector either, but, obviously, mechanical tightness is important for long-term trouble-free service.

Dirt cheap test gear

From Michael Fratus: A working, inexpensive, portable AM/FM broadcast band radio can often be used as a substitute for more costly test gear when building, testing, or repairing ham equipment. Used with its internal 9 volt battery, the portable BC band radio can prove to be the safest and most versatile choice at times.

The AM band oscillator, for example, can be utilized as a signal source for a 1 MHz to 2 MHz CW signal when troubleshooting or signal injecting. This signal can be tapped from the AM tuning capacitor, via a 100 pF disc capacitor, and brought out for injection into the ham receiver under test. The AM oscillator can be modified to generate a slightly different range by adjusting or removing the coil's tuning slug, or by varying the number of turns on the coil itself through experimentation.

The 455 kHz AM band IF circuit can be coupled, via a 100 pF disc cap, to the ham receiver under test for checking either the 455 kHz conversion circuitry (by feeding the ham receiver's signal into the AM portable's known-to-be-good IF chain) or for injection into the ham receiver (by feeding the AM IF signal into the ham receiver's IF chain).

The FM portion of the portable receiver can offer the same options—checking the 10.7 MHz conversion stage or for feeding a 10.7 MHz known IF signal back into the ham receiver via a 10 pF disc cap. The FM oscillator can also be used as a signal source, from 98 MHz to 118 MHz, coupled via a 10 pF or so disc cap,

and the basic oscillator frequency range can be easily changed by spreading or compressing turns on the oscillator coil itself or by winding a completely new coil.

The audio section of the portable can be tapped, via a .1 μF or higher non-polarized coupling cap, to the center lug on the volume control. Again, audio can either be fed into the portable or injected from the portable into the ham band receiver. Higher level audio, of course, is available at the above-ground speaker terminal.

I usually start by finding all of these points on the portable's circuit board, attach the appropriate capacitor, then bring the cap's lead out via a small hole drilled in the plastic case. A loop on the outside end of the capacitor's lead makes a nice point for gripping with an alligator clip. Don't forget to bring out an insulated wire from the circuit board's ground and to mark all of the "tap" points for easy identification later on.

Excessive voltages can sometimes destroy one of these small portable radios, but even if you do damage it at some point, you can replace it for a couple of dollars at the next hamfest!

Switch to manual(s)

From Peter Albright AA2AD: Servicing, at almost any level, is made much easier by having the published service data for the specific piece of gear in question at your fingertips. While many problems can be located and rectified without the service literature, just having the schematic diagram can provide a quantum leap in servicing efficiency. Perhaps because of ham radio's more technical nature, ham equipment manufacturers have traditionally been more likely to include at least some service information (albeit, perhaps just a schematic diagram) along with their operating manual, but some are no longer doing even that.

Full-blown service manuals are available from the manufacturer for most ham transceivers, and they are a good investment if you intend to do any repair work yourself. The service manual often contains an informative "how-it-works" section, in addition to the schematics, PC board layouts, parts listings and setup, and adjustment procedures. Even if you never use the service manual yourself, you can often recoup its investment when you later sell the rig! Many "ham friend" service techs won't go very deeply into your radio without the aid of a service manual (equipment today is just too complicated to risk it) so servicing information will often be required by independent technicians. It's a good idea to procure a service manual for your new transceiver as soon as you can, since as time goes on they often become harder to find.

One source for older service manuals (if the manufacturer tells you that he no longer stocks it) may be Howard W. Sams Company in Indianapolis (Tel: 215-725-6722).Though often associated more with consumer electronic servicing information, Sams does have a photocopy service information index that lists many ham radio transceivers and accessories, so they're worth checking with before you give up completely.

Some ham equipment dealers also stock service manuals and a few quick calls to them can be rewarding. The ham VHF/UHF packet network is also a possibility. If you don't have packet access yourself, a ham friend who does can put out a "WANT @ ALLUSA" bulletin for the manual you're looking for (we see them every day). Don't forget to mention that you're more than willing to pay all associated expenses for obtaining the copy that you need, and provide your home phone number for the quickest response. Some voice repeater nets have a "Swap & Shop" segment in their net-night gatherings, and putting out a "wanted" request there might be worthwhile at times. *73* also has a want-to-find public service column called "Ham Help" that can be effective after you've exhausted the other avenues.

Servicing information is worth its weight in gold when you need it, so play it smart and don't put it off until the last minute, when your station is down because of an inoperative key piece of gear.

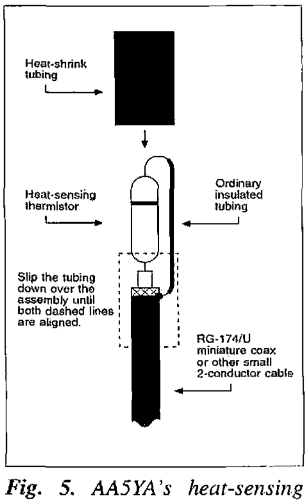

Fig. 5. AA5YA's heat-sensing thermistor's wiring details. See text for complete description.

Free mountings

From Joel Masur AA5YA: If you need to mount a thermistor on a chassis or heat sink to signal a cooling fan or other circuit when to turn on, try this inexpensive method.

If you know someone who works with the power company, or you can make friends with one of their linemen, the blown "in-line disconnect switch" fuses that they use can be disassembled and the threaded end-cap recycled as a rugged mounting for an in-line, pigtail thermistor mount. These "in-line disconnect switches" have a door that's spring-loaded and drops down whenever the pole service fuse blows (it sounds like an M-80 firecracker going off!). The parts I'll describe are the throw-away end caps. They're already threaded for 1/4-28 MS, so only a 1/4" hole needs to be drilled into the body of the cap. Then, using a glass-encapsulated thermistor (about the size of a 1/8 watt resistor) such as the Digi-Key #KC009G 10k ohm NTC unit, bend one of the leads so that both are parallel to the thermistor's body. Now, carefully solder the correct length of RG-174/U miniature coax cable to the staggered leads (see **Fig. 5**). Insert the wired thermistor into the end-cap body (leaving it about 1/4" from the top of the fitting) and cement it in place—at the entrance only—using clear silicone adhesive. The thermistor itself should be in contact with the free air inside the fitting, or white silicone heat-sink grease can be used to transfer the heat picked up by the fitting's body over to the thermistor. You'll now have a neat, protected, metal-encased thermistor package that can be bulkhead-mounted wherever you need to sense a thermal rise.

Another item that can be used for the same purpose can often be found at hamfests or swap meets. Look for an older Ohmite No. Q120 Model E wire-wound porcelain rheostat. When you disassemble it you'll end up with a threaded brass barrel with a shoulder on it, and a nice brass nut to match. The wired thermistor (as above) can be cemented inside, again providing a nice-looking, protective mounting arrangement. By the way, if you're able to acquire the blown power line cartridge fuses mentioned first, the tails on these fuses are made of heavy-gauge, stranded, tinned copper wire and are great for short high-current bonding straps or for connecting stud-mounted power rectifier diodes together. A two-for-one bonus!

The thermistor that Joel refers to in his tip can be obtained from Digi-Key, 701 Brooks Avenue South, Thief River Falls, MN 56701-0677 (Tel: 1-800-344-4539).

Cool it!

From Ken Guge K9KPM: If left idling too long, the copper-clad tip on a small soldering iron can become too hot and begin to build up oxidation. It's a problem that's easily overcome, however, by simply installing an on/off switch in the AC line cord to the iron. Use the larger type of in-line switch (the type that uses screw connection terminals on the inside) and cut just one of the iron's AC wires at the point where the switch will be easy to access. Now connect one end of each half of the cut wire to each of the switch's terminals. Don't stop there, though; also place a small silicon diode across the switch terminals. Something like a 1N4005 will do nicely (the diode's polarity isn't important in this application). Now the diode is in parallel with the switch, so the iron isn't off completely when the switch is open; that's because

the diode keeps it running at about half voltage (only the positive or negative halves of the AC sine wave get through to the iron, it doesn't matter which). When you want the iron to "idle down," simply throw the switch to "off" and it will drop to half power. When you begin soldering again, throw the switch to "on" (shorting out the diode) and the iron will come back up to full soldering temperature quickly. Most importantly, it keeps the tip from oxidizing as badly and prolongs its life significantly.

If you'd like to go one step further, mount a wall dimmer into a 4" x 4" electrical box, along with a duplex outlet. Then connect an AC line cord of convenient length to the dimmer (following the dimmer's instructions), but instead of the dimmer's output going to a ceiling lamp, it will go to the duplex outlet instead. Now when you plug your soldering iron into that duplex outlet you'll have continuously variable heat control for any size job, plus half-level for idling via the in-line switch from above. A small "night light" plugged into the remaining outlet on the duplex pair will visually show you roughly where the dimmer—and your iron—are set.

Ken's idea concludes another "Ham To Ham" column, our 10th. Thanks to all who've taken the time to write and offer their favorite suggestions so that the rest of us can benefit from their knowledge and experience. I hope you feel as I do, that this is in the very best of traditions of our hobby—one ham helping another...Ham To Ham. Let's see your ideas in print here.

Fixing oscilloscopes

In a previous series of articles, we explored the use of the mighty oscilloscope. Fact is, you just can't do much serious electronics work without one. Once you get used to having a scope on your bench, you'll find yourself depending on it for so many tasks that you'll wonder how you ever got along without one. So, it can be quite a problem when "old faithful" breaks down. After all, how are you going to fix your scope without a scope??

If you can, borrow one! If you can't do that, you will have to try and repair the thing with lesser instruments, like your DVM and frequency counter. Either way, fixing a scope can be a challenge. Like all repair jobs, though, sometimes it's a bear and sometimes it's a piece of cake. (Hmmm, wonder if bears like cake?)

Been there, done that?

In some ways, an oscilloscope is like a TV set, particularly because both have CRTs. That means they both use very high voltages to create and manipulate the beam that hits the screen and forms the image, and they both have circuits relating to horizontal and vertical movement of the beam.

That's where the similarities end, though. Unlike computer monitors, which are very like TV sets, scopes use some fundamentally different techniques to operate the CRT, causing them to have very different circuits and overall structure. Let's take a look, but, before we do, here comes the safety lecture again:

Like TV sets, scopes use thousands of volts to operate their RTs. Unlike TVs, though, most scopes connect the highest voltage (for the CRT anode) right at the back of the tube, on one of the regular socket pins. Compared to the nice, insulated anode cap on the side of a TV CRT, the high voltage in a scope can be much more exposed. So *be careful!* All the TV servicing rules apply, such as using only one hand when exploring or adjusting a powered unit, and discharging the power supply caps and CRT anode before messing with them.

Vive la difference!

So what makes a scope so different from a TV set? Primarily, the dissimilarities result from the scope's requirement of widely variable scan rates. A TV always scans its CRT at the same rate, which is about 15.735 kHz horizontal and 60 Hz vertical. A scope, though, can scan its tube at any rate you choose, allowing the viewing of all kinds of different signals with all manner of time periods. Without the variable scan rate, scopes would be fairly useless.

Gimme a ring

In a TV set, the beam is swept across the face of the tube by a magnetic field, which is generated by a set of coils placed around the neck of the tube. Current through the coils creates the field, sweeping the beam. Unfortunately, it's difficult to use magnetic deflection of the beam unless the scan rate is constant, because those coils have plenty of inductance (which is what makes them work, of course) and must be used in a fairly resonant condition. Essentially, it's the same situation as with SWR on your antenna: If you try and pump nonresonant energy into the deflection coil, some of it will come back at you and cause distortion of the original current waveform, or even heating and destruction of the coils, the driving amplifier, or both. That's one reason some computer monitors can be damaged if you try to run them at the wrong scan rate, and also why multiscan monitors cost more; they need special circuits to handle the different rates. Even with the multiscan units, the range of scan rates is fairly limited, varying by perhaps a few hundred Hz for the vertical, and a few tens of kHz for the horizontal.

On a scope, you might want to change the scan rate from 0.2 seconds to 0.2 *microseconds* as you examine a waveform. So, you can see why magnetic deflection just isn't practical; you're dealing with scan rate ratios of over a million to one! The way around it is to use another form of deflection: electrostatic. That's just a fancy way of saying that the presence of one electrical field can alter another. Just as the anode voltage on a CRT's face will attract the cathode's electrons to it (which is the same effect as the plate voltage on any tube, for that matter) so will another strong, positive voltage pull those electrons toward it when it's placed on the *side* of the tube. So, a scope tube has four electrode plates in its neck, one for each of the required directions of pull.

> **"A scope can scan its tube at any rate you choose, allowing the viewing of all kinds of different signals with all manner of time periods"**

High voltage

In a TV set, the high voltage is nearly always generated by the horizontal circuitry, using a "flyback" transformer. Like the deflection yoke (set of coils), the flyback is resonant at the horizontal scan rate, and can't be used over a wide frequency range. Trying to do so can overheat the flyback and, eventually, destroy it. Even more than the yoke's, the flyback's resonance requirement limits the range of available scan rates.

Thus, in a scope, the scanning and high voltage circuits must be kept separate, so while a TV can't make anything at all on the screen unless the horizontal circuits are running, the same is not true on a scope. (In fact, there are occasions when you may want to turn the horizontal scan of your scope off, such as for X–Y signal monitoring, where one signal moves the beam up and down and another one moves it left and right.)

The other elements of a scope are somewhat different, too. On a TV, the beam is scanned in a raster pattern, and the only modulation of that beam is of its intensity. On a scope, intensity is usually constant, and the modulation is of the *direction* of the beam! That means the scanning circuitry has to have amplifiers as well as oscillators. A typical scope has two amplifiers for the vertical direction, allowing the viewing of two simultaneous waveforms. The horizontal section does have an oscillator, but it often also has an amplifier, letting you use an external signal to drive the beam horizontally, for display of X–Y signal patterns.

Just as a TV has sync circuitry to keep the position of the beam lined up with the original picture, a scope has a trigger circuit to synchronize the horizontal scan with some repetitive point on the incoming signal. This is a crucial function: without it you can't see anything more than a blur on the screen.

Finally, a scope depends on a power supply, just as does any other circuit. Most scope power supplies provide several different voltages, the loss of any of which will severely disturb the scope's operation.

Where to start?

Well, what's wrong with your scope? If it died altogether, the power supply is the first place to look, of course. If the power light doesn't come on, check the fuse, and then start troubleshooting the low–voltage supply, using standard repair techniques. Many scopes use simple, linear supplies, although some use switchers. If yours is a switcher, be awfully careful when servicing it. If you don't know how to

work on switchers, find somebody who does, because they can be dangerous. In any event, simple power supply problems are likely to be caused by failed diodes, transistors and voltage regulators, or perhaps a shorted electrolytic cap.

If the outputs from the low voltage power supply are working, take a look at the back of the CRT. Its filament should glow, although the glow can be pretty dim. If you see nothing at all, follow the leads back to the board and see where the voltage disappears. It's possible for the filament to be driven from a part of the high–voltage supply, and the drive may be pulsed, so you might not be able to read it on a voltmeter. That's where another scope really comes in handy. By the way, although the filament could be open, I've never run into that problem.

Various other voltages are required on the tube in order to make a trace, and many are generated from "boost" voltages, which are intermediate voltages created by the high–voltage supply, just like in a TV set. With a TV, you can usually tell if there's high voltage getting to the tube by touching the face of the screen and feeling the crackle—not so with a scope! The voltages are lower (although they're still in the thousands), and I've never been able to feel a crackle on a scope. So, if there's no trace, it may not be obvious whether there's high voltage or not. Assume there is, as far as safety is concerned; there may still be enough voltage to kill you. To be sure, you'll have to measure it, and that requires a special probe. High–voltage failure is nowhere near as common on a scope as it is with TV sets, due to the lower voltages required, I guess. I did have one old scope that died of high–voltage failure, but it was pretty obvious, as the trace went out of focus and bloomed, a sure indicator of dying high voltage.

Well, we've barely scratched the surface of scope repair. Next time, we'll dig into it quite a bit more. Until then, 73 de KB1UM.

Got any ham related photos suitable for a 73 cover-pix??? Call Frances 800-274-7373.

HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92633

Testing the Vector–Finder

As I pulled into the starting area of one of my first 2 meter hidden transmitter hunt at a hamfest in San Diego about 20 years ago, I thought I couldn't be better prepared. I had my four-element radio direction finding (RDF) quad on a mast going out of the passenger-side window, a big external S-meter on the dash, and an RF attenuator to knock the signal down into S-meter range as I closed in. The back seat was full of maps and on-foot "sniffing" gear. I was confident that I would soon bag the hidden T and have a prize in my hands.

Then the signal came on the air. What's this? It was on for a half second, then off for a half second, like the tick of a clock. And every time it came on, my meter reading was different! Sure enough, the hider had programmed his rig to change output power each time it made a half-second transmission. My big S-meter bounced around wildly as I turned the quad. Spinning it rapidly didn't help me get a bearing, because the transmissions were too short. Turning it really slowly wasn't any better, due to flutter on the signal as I began to move.

I eventually found the hidden transmitter, which was near a rutty gravel road in the mountains. All along the way, I resolved that in future I would carry some RDF equipment that is immune to changes in the amplitude of the signal.

TDOA points the way

The time-difference-of-arrival (TDOA) technique fills the need for a non-amplitude-based RDF system by picking up the target signal on two or more antennas. The relative times at which the signal wavefront strikes each antenna give clues about its incoming direction. Some sophisticated military RDF systems use this principle at fixed-site installations to get highly accurate bearings on shortwave signals. Both the incoming azimuth and elevation angles can be determined, so the distance to skip-propagated stations can be calculated. But resolving ambiguities, determining elevation, and achieving high accuracy in a non-rotating TDOA system requires at least three antennas and a very large, fast computer for signal processing. We're talking megabucks, so that's not practical for ham radio, at least not yet.

"The VF-142Q is as close as you can get to plug-and-play RDF."

Fortunately, there is a much easier way to use the TDOA principle. **Fig. 1** shows a simple array that will give sharp bearings with your VHF-FM receiver or handie-talkie. Two vertical dipoles are at the ends of a horizontal bar, supported by a short mast. It is called a "narrow aperture TDOA" because the dipoles must be a half wavelength or less apart for proper operation. A diode network switches the receiver RF input electronically from one dipole to the other very rapidly; say, 500 times per second.

The signal from Transmitter #1 arrives at Antenna A before it arrives at Antenna B. Conversely, the signal from Transmitter #3 arrives at Antenna B before Antenna A. Because the wavefronts from these two transmitters don't arrive at both antennas simultaneously, there is an abrupt phase change of the receiver input signal during the switching when receiving either one. This phase jump is detected by the receiver's FM discriminator and sent to the speaker. It sounds like an audio tone superimposed on the received audio. The tone frequency is constant at the switching rate, but its amplitude increases with increasing phase difference between the signals arriving at the two antennas.

The signal from Transmitter #2 arrives at both antennas simultaneously. Thus, there is no phase jump during switching and the tone is minimized or disappears entirely. When you have rotated the mast of a TDOA antenna set to null the tone on an incoming signal, you know that it is along the line of bearing of Transmitter #2.

No receiver S-meter is needed to get bearings with a TDOA set. Your ear easily detects the tone null. The bearing indication is very sharp, compared to the broad forward lobe of a yagi or quad. There are no strong-signal overload problems because the process uses phase, not amplitude.

The first TDOA RDF project for hams was by David Geiser WA2ANU in *QST*, July 1981. His Double Ducky Direction Finder had two vertical "rubber duckies" mounted about a foot apart on a grounded screen. This simple no-indicator TDOA implementation is still popular as a "starter" RDF system for fledgling T-hunters. You may have seen kits for similar versions, with duckies or "batwing" antennas, selling for less than $30 at a hamfest or swap meet in your area.

The packaging and antenna systems in most of these rudimentary sets leave a lot to be desired. Their biggest flaw is that they have a "figure-8" directional pattern with no built-in method for resolving the ambiguity. That's right, they give you two possible directions to the hidden

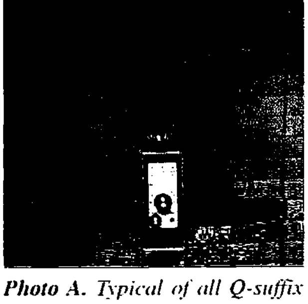

Photo A. Typical of all Q-suffix Vector-Finder RDF sets, the VF-142Q has dual dipole antennas and left-right LED indicators. The on-off push-button is mounted on the handle, like a trigger.

***Photo B.** The 2-1/2" x 6" x 6-1/4" Vector-Finder control box includes a tone pitch control, speaker, and oil-filled magnetic compass.*

transmitter, not one. When you turn the antenna and get a sharp null that indicates the signal source lies directly in front of you, it could just as easily be directly behind you! No serious T-hunter wants that.

WA2ANU realized that polarity of the phase jumps at the receiver discriminator output can be used to resolve the ambiguity. He explained the principle in his original article and in a follow-up article in the May 1982 issue of *QST*. Included was an improved Double Ducky design featuring a left-right meter indicator. With it, the TDOA technique was truly useful. Since then, several home-brew TDOA projects have been published and commercial versions have come to market. Some give left-right indications on a zero-center panel meter, while others use a pair of light-emitting diodes (LEDs).

The VF-142Q

This month, "Homing In" looks at the Vector-Finder VF-142Q, manufactured by Radio Engineers. Bob Decesari WA9GDZ formed this company in 1979 as a part-time business, and went full-time three years later. His company brought out its first TDOA RDF set for boaters in the 1980s, but I paid little attention to it because it had bidirectional ambiguity. Now Radio Engineers has added the Q-suffix series of Vector-Finders with left-right indicators to its product lineup.

The VF-142Q (**Photo A**) is as close as you can get to plug-and-play RDF. Just unfold the antenna arms, extend the whips, attach a 9-volt battery, then connect the cable to your receiver's antenna connector (BNC type supplied) and extension speaker jack. The unit comes completely assembled and tested. It is not available in kit form.

WA9GDZ put careful thought into the mechanical design of the Vector-Finder series. Antenna supports are hinged to swing out for use and to fold against the control box for storage and transport. When fully extended, the VF-142Q dipoles are 38-1/2" long, just right for 2 meters. The 17" spacing between dipoles permits operation up to 300 MHz. An oil-filled magnetic compass atop the control box makes it easy to read bearings while on foot in the field. A speaker with volume control is included, so you can hear the receiver with the audio pick-off plug inserted (**Photo B**).

A good report card

The unit I tested had good electrical balance in the antenna system and produced very sharp tone nulls on both the 2 and 1-1/4 meter bands. The left-right indicators tended to flicker on and off as turned in a full circle, which led me at first to think that the they were not working properly. But with a little practice, I came to realize that the LEDs are quite accurate and steady within ± 20 degrees of the line of bearing, where it matters the most.

I discovered that the best technique for taking a bearing with the VF-142Q is to turn slowly in a circle while listening carefully for the two nulls in the DF tone, ignoring the LED indicators for the moment. If your surroundings are noisy, it may help to plug an earphone into the front panel jack to better detect the tone nulls. When you have found the nulls, face one, watch the LEDs, and rock the unit slightly to the left and right of the bearing line. If you are facing the signal source, the "go right" LED will come on as you rotate to the left. Conversely, the "go left" indicator will light as you rotate to the right. If the opposite happens, you are facing away from the incoming signal. By walking, turning, and following the null and lights, you will approach the hidden transmitter more or less directly.

An important test of a dual-antenna TDOA RDF set is how it performs when there is high audio deviation on the signal, as often happens when hidden T's have "foxbox" tone generators. A few TDOA circuits I have evaluated in the past got good bearings on dead carriers, but the indicators were unusable when there was voice, tones, or noise on the signal. The VF-142Q processor did a good job of rejecting modulation. In the ± 20 degree range around the null, voice and tones had little or no effect on the left-right indicators. If a particular modulating tone caused blinking, it could be minimized by changing the antenna switching rate with the front panel pitch control.

Another problem with some TDOA sets is unreliable operation as battery voltage sags. Duracell specifies that a standard 9-volt alkaline battery reaches end of life at 4.8 volts. The VF-142Q produced reliable bearings all the way down to that voltage, though the LEDs became very dim. Still, this was much better than another brand I have tested, which stopped working at 7.8 volts.

I had only a few minor complaints about the VF-142Q. Light from the miniature green indicators is nearly washed out by sunlight. A hood or larger LEDs might be an improvement. The antenna switching action produces some RF hash, which closes the receiver squelch on weak signals. To counter this, I opened the squelch control completely when taking bearings on a distant T. Since the dipoles are electrically disconnected from the receiver when the trigger is not being depressed, weak signals must be monitored with the DF buzz in the background. It would be nice to have a "zero frequency" position on the pitch control so the dipoles could be used to listen to weak signals, or for transmitting.

There is no bracing to hold the four pivoting collapsible whips in place, so the dipoles can easily get knocked out of position when you are crashing through the brush on foot. The antenna arms are not detachable from the control box, so the unit cannot be easily mounted on a vehicle for mobile T-hunting. Last but not least, the bolt holding the antenna supports protrudes 3/4" from the back case, making it awkward to lay the unit on its back when you pause during the hunt.

Keep in mind that there are certain RDF situations where all TDOA models are at a disadvantage. Horizontally-polarized signals are much more difficult to track than vertical, because signal reflections are enhanced relative to the direct signal when received by the vertical dipoles. Very weak signals may be masked by noise from antenna switching. A properly polarized beam or quad works better for RDF in these special situations.

Tracking in the presence of many signal reflections (inside a building, for instance) is difficult with a TDOA. The multiple paths may make it impossible to get a good null, or the null may be off the correct line of bearing. The best way to combat this problem is to keep moving in the general direction of the signal source and take frequent bearings as you walk along.

Since amplitude of the incoming signal is ignored when your TDOA set takes bearings, you must remember to pay attention to signal level as you hunt. I have seen T-hunters following a TDOA's line-of-bearing null walk right over a buried hidden transmitter. They didn't realize that the signal had gotten super-strong and then diminished. Consider carrying along a field strength meter in addition to your TDOA set so you can tell when you are very close to the hidden T. If you can't do that, check for "You are here!" signal strength by disconnecting the receiver antenna or listening on the third harmonic frequency with your dual-bander. Take bearings continuously and verify your left-right indications to be sure you have not gone too far.

Where to get one

The VF-142Q RDF is available for $239.95, plus tax and shipping, directly from Radio Engineers, 7969 Engineer Road, Suite

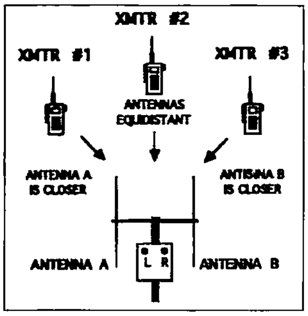

Fig. 1. TDOA RDF sets such as the VF–142Q get bearings by determining which of its two vertical antennas is closest to the transmitter. Differences in arrival time produce differences in the phase of the signals from each antenna. Accordingly, some hams prefer to call these units "phase front detectors."

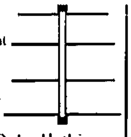
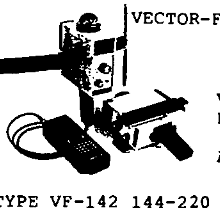
102, San Diego, CA 92111, phone (619) 565–1319. In addition, Radio Engineers makes the VF-142QM, which has a slightly different configuration of the antenna support arms. This allows them to be positioned closer together, so the unit can be operated up to 500 MHz when used with a suitable receiver. It sells for $289.95. Be sure to order a model with the Q suffix so your unit will have left-right indicators.

The TDOA method of RDF is favored by some search and rescue volunteers for tracking aircraft Emergency Locator Transmitters (ELTs). These beacons are AM signals in the AM-only aircraft band, but the TDOA RDF method requires an FM receiver. For tracking ELTs, Radio Engineers makes two Vector-Finder models called "ELT Stalkers." They include an upconverter to shift incoming 121.5 MHz signals to 146.52 MHz, where they can be received and tracked with a 2 meter FM receiver. Converters to 2 meters for 243 and 406 MHz ELT frequencies are not provided. The VF-121Q ELT Stalker (up to 300 MHz) sells for $379.95, and the VF-121QM (up to 500 MHz) sells for $409.95.

A TDOA RDF sniffer is an important addition to your T-hunting bag of tricks. When signals are strong, vertical, and in the clear, it will give sharper bearings than a beam. Bearings will be easy to take, even if the fox transmitter is changing power. Its inherently broadband antenna system will give you RDF capability over a wide frequency range.

Do you know of a new or novel RDF product? Tell me about it, so it can be considered for a "Homing In" review. Write to the address atop this article or send e-mail to me at Homingin@aol.com or 75236.2165@compuserve.com. 73





ATV

Ham Television

Bill Brown WB8ELK
139 Angela Dr. Apt. B
Madison AL 35758
bbrown@hiwaay.net

For those of you who enjoy surfing the Internet, you'll find lots of ATV information online. A number of ATV groups and individuals have taken advantage of the capabilities of the World Wide Web to provide net surfers with a wide variety of entertaining web pages. You'll find basic information about getting started in ATV, pictures of local ATVers, circuit diagrams, construction articles, product reviews and recommendations, event schedules and announcements, as well as operating hints. A couple of groups actually offer live digitized still-frame images of their ATV repeater so you can check in remotely from anywhere in the world. WA6ZJG in Alameda, California, even has a live tower camera that updates every three minutes that you can rotate by clicking your mouse!

"A couple of groups actually offer live digitized still-frame images of their ATV repeater so you can check in remotely from anywhere in the world."

The real power of these Internet web sites is the linking capabilities to other pages anywhere in the world. You might be cruising through the Arizona site and with one mouse click you are instantly transported to the German ATV. I've found that as you cruise through each group's pages you'll find all kinds of interesting links to related information about television, video digitizers, R/C aircraft, kites, and balloons. Just be sure that you have a lot of time set aside before you begin browsing since, once you've started cruising these ATV sites, it'll be difficult to stop.

ATV web sites

The URL address given for the following groups should be entered into your web browser to access each site; you'll find that each group usually will have links set up to other ATV pages. The Arizona Amateurs on ATV page, the ATN group of Southern California, and the German group appear to have the most extensive list of links that I have found. Once you have found the link page, you can cruise to all of the other groups easily with just one mouse click. It's a good idea to bookmark each group's page so you can return easily without having to type in the address.

Alabama

The Tennessee Valley ATV group has a web page giving a description of their repeater system on top of Monte Sano mountain in Huntsville, as well as operating news and net times. *http://fly.hiwaay.net/~bbrown/tvatv.htm*

Arizona

This page provides a description of the Solent Club for Amateur Radio & Television (SCART). *http://www.inside-info.co.uk/scart.htm*

Utah

The Utah ATV home page is managed by Clint KA7OEI and describes the WB7FID and KA7OEI ATV repeaters. They offer links to a variety of ATV related activities (balloons, mountaintopping, R/C planes, and astronomy experiments). *http://uugate.aim.utah.edu/utah_atv/root.html*

SSTV

This multimedia page has loads of information about Slow-Scan TV. A must-see page for anyone with an interest in this popular mode. *http://www.ultranet.com/~sstv/*

R/C Aircraft ATV

Carl Berry K5MWN has put together a very detailed and informative site that describes how to build a remotely-powered vehicle with an R/C plane, and a converted arcade game that actually puts you in the pilot's seat via ATV and telemetry. His system is called the Cyclops. Included are links to other R/C sites on the web. *http://198.83.140.5/~cyclops/cyclops.html*

High altitude balloons

For those of you with interests in flying ATV onboard high altitude weather balloons, or those who would like to know when a flight is scheduled, there are several sites that have popped up from the more active balloon groups across the country. These sites can all be accessed via the EOSS (Edge of Space Sciences) home page at *http://www.usa.net/~rickvg/eoss.htm*; links to the other balloon groups can be found in their "Information about other Balloon Groups" section. You'll find telemetry information, launch and recovery photos as well as several incredible photos taken from the edge of space.

There is a Amateur Radio Balloon Symposium in Iowa this July; check out the detailed information about the symposium in the "News from other Balloon Groups" section.

"As you cruise through each group's pages you'll find all kinds of interesting links to related information about television, video digitizers, R/C aircraft, kites, and balloons."

Kites

This page had some intriguing info about using telemetry in their altitude record attempts for kiting. Fun reading. *http://www.magic.ca/~kite*

Internet live cameras

Check out Leonard's Cam World page for links to numerous live camera sites accessible via the Internet. *http://jax.jaxnet.com/~len/camera.html*

Netcruising

I hope you enjoy your cruise down the information highway. If your group is online and not listed here, please feel free to E-mail me at *bbrown@hiwaay.net* and I'll update the information in a future column. 73

CARR'S CORNER

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

Radials For Your Antenna

Radials are quarter-wavelength (usually) pieces of wire connected to the ground side of the transmission line to an antenna. These radials can be on the surface of the Earth, under the surface, or elevated, depending on the particular antenna. The radials are used to form a counterpoise ground, i.e. an artificial ground plane. It is seen by the antenna as essentially the same as the ground.

"Whatever type of antenna you put up, make sure that it is in a location where it cannot possibly fall over and hit a power line."

Ground level configurations should be buried, rather than on the surface, to prevent injury to people passing by, either from RF burns or stumbling over the fool wire. But what do you do in a limited space situation?

Figs. 1 and **2** show the most common forms of radial installation. In **Fig. 1** we see the radials connected to a vertical antenna that is mounted above the ground (usually quarter-wavelength or some convenient height). The radials are connected to the shield of the coaxial cable. They may be at a drooping angle (as shown) or 90° from the radiator element (i.e. horizontal to the ground).

The version shown in **Fig. 2** is used with ground-mounted verticals (the base insulator is not shown here). A ground rod is recommended, and it should be a long one. The television type (typically three or four feet long) is not sufficient. Use an eight-foot copper or copper-clad steel ground rod for the best results. The shield of the coaxial cable is connected to the ground rod. The radials are fanned out from the top of the ground rod and extended as far as necessary.

The radials in this illustration are buried several inches below the surface in order to prevent anyone from tripping on them; some nasty injuries can result from such a fall. Also, wires buried underground tend to come to the surface from time to time, so either bury them deep (like below the frost line, which is 28 inches in my neighborhood) or perform regular inspections to ensure that they are still where they are supposed to be—underground.

The radials should be made of AWG 14 or thicker wire, and the wire can be either insulated or bare. Even underground it matters little which is used. A lot of people use the same type of wire that is used for antennas in their radials, AWG 14 copper-clad steel wire.

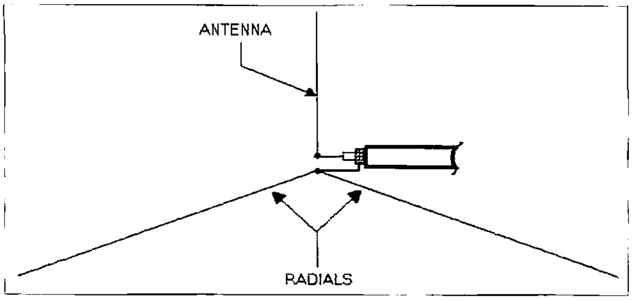

Fig. 1. Radials connected to a vertical antenna that is mounted above the ground. The radials are connected to the shield of the coaxial cable.

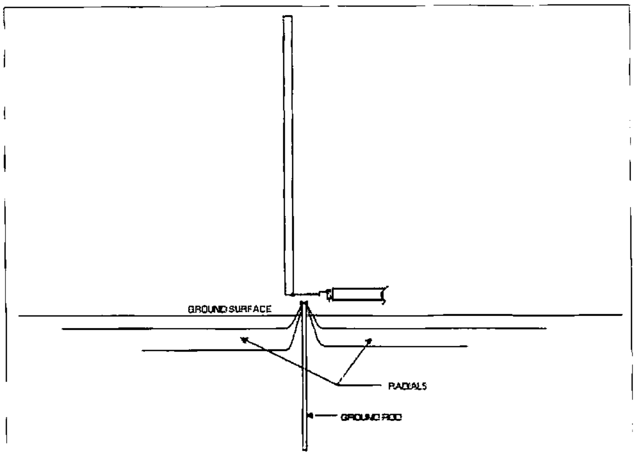

Fig. 2. Radial installation used with ground-mounted verticals (base insulator not shown).

Fig. 3 shows the method for connecting the radials to the ground rod. There is almost always some sort of wire collar on commercially produced ground rods. If not, then get a wire clamp from the electrical section of a do-it-yourself hardware store (some of which also sell ground rods of suitable length). A relatively healthy number of radials can be accommodated under the clamp. Make sure that the clamp is tight, and that the screw or hex nut holding the wires is well set. The wire to the shield side of the coaxial cable is also connected at this point.

How many radials?

Boy! Am I gonna get hollered at! Every time I write about radials the number of radials goes up. And it seems that there is a lot more heat than light out there in Readerland over this matter. But cool off, and I'll share my opinion with you... and it's an opinion that is backed up by both practical experience and the antenna engineering literature.

The minimum number of radials is one. But a one-radial antenna system isn't going to work very well. I've done it, but only as a get-on-the-air-as-fast-as-possible temporary measure. One time, right after we moved into our first house, I mounted a 20 meter Hustler mobile antenna to an upstairs windowsill, and ran a 16-foot radial out to a nearby tree. It worked, and worked pretty well considering what it was—and didn't even burn up my aging Heathkit HW-101 transceiver. But it didn't work nearly as well as the half-wavelength dipole and commercial trap vertical that went up two weeks later. As a practical minimum, you need at least two radials for each band of operation, and four radials per band is better. The radials should be spread out symmetrically around the antenna.

Now that we've established a practical minimum, what does the antenna engineering literature say? The charts and graphs show that up to 120 radials per band are useful. Commercial radio stations operating in the medium waveband, AM BCB and under, tend to use that many radials. But if you look at the charts, you see a distinct knee between 14 and 18 radials where there is a downward trend in the effectiveness of each additional radial. In other words, it's a point of diminishing returns. One of the most vicious reader letters I've ever received flamed me for recommending no more than 16 radials, and held fast to the 120 radial scheme. It didn't make any difference that sources such as Bill Orr's *Radio Handbook*, *The ARRL Antenna Book* and other well respected sources—including two of the principal college-

level antenna textbooks—confirmed the 16-radial-per-band practical limit. Oh well, that same idiot also flamed me for claiming that the maximum feed point impedance of the usual quarter-wavelength vertical is 37 ohms ... with four pages of calculus he proved conclusively that the real value is 36.6 ohms (sighhh).

> ***"Wires buried underground tend to come to the surface from time to time, so either bury them deep or perform regular inspections to ensure that they are still where they are supposed to be—underground."***

Limited space radial layout

If you live on a small lot, then the radials problem is a little more daunting, but it's not insurmountable. A representative solution is shown in **Fig. 4.** The radials shown in textbooks are straight, and that is the preferred configuration. But if you don't have the space, then you need to use some variant of the two paths shown in **Fig. 4.** The radial can either go around the perimeter of the property, or zigzag back and forth in either a triangle or rectangle pattern (the latter is shown here). I've even tacked radials to the baseboard of a student boardinghouse room (not recommended over a few watts QRP power levels).

Antenna safety

Every time I write about antenna construction I like to talk a little bit about safety. The issue never seems too old or too stale, because a lot of people out there never seem to get the word. Antenna erection does not have to be dangerous, but if you do it wrong it can be very dangerous. Antennas are deceptive because they are usually quite lightweight, and can easily be lifted. I have no trouble lifting my trap vertical and holding it aloft ... on a windless day. But if even a little wind is blowing (and it almost always is), then the sail area of the antenna makes it a lot heavier (or so it seems). Always use a buddy system when erecting antennas. I have a bad back caused by *not* following my own advice.

Another issue is electrical safety. Don't ever, *ever*, ***ever*** toss an antenna wire over the power lines. ***Ever***. Period. Also, whatever type of antenna you put up, make sure that it is in a location where it cannot possibly fall over and hit the power line.

The last issue is to be careful when digging to lay down radials. You really don't want to hit water lines, sewer lines, buried electrical service lines, or gas lines. Heck, I know one property where a long distance oil pipeline runs beneath the surface. If you don't know where these lines are, try to guess by looking at the locations of the meters at the street, and the service entrance at the house. Hint: Most surveyors' plats (you know, those map-like papers you get at settlement) show the locations of the buried services. They should also be on maps at the local government offices (although you might have to go to two or three departments!). The utility companies can also help.

Be safe, be happy or, as Mr. Spock put it, "Live long and prosper."

Connections

I can be reached at P.O. Box 1099, Falls Church VA 22041, or via E-mail at CARRJJ@AOL.COM. I welcome your correspondence. One thing does tend to annoy me, though. Please don't call me on the telephone. A number of readers have done that recently. In the past, I didn't mind so much because only a few people every year called, but the traffic has increased quite a bit. Although I try to be polite and helpful, it almost always interferes with some activity. I arise every morning in time to arrive at my office at 7 a.m., and that means I go to bed early. And while the caller almost always thinks he has kept to the polite "before 10 p.m." rule, the call nonetheless wakes me up. I make it a point to answer all E-mail and try to answer as much snail mail as I have time for, so please don't call. 73

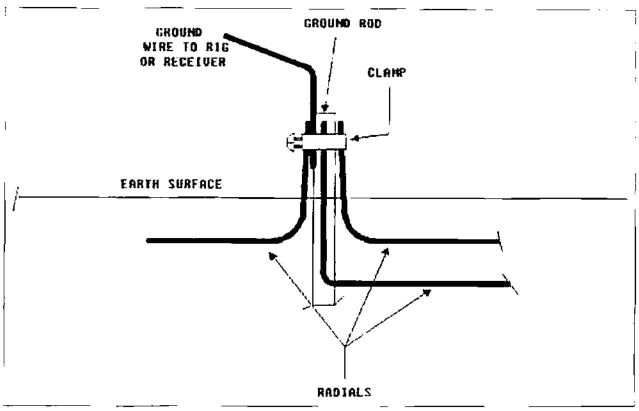

Fig. 3. *Method for connecting the radials to the ground rod.*

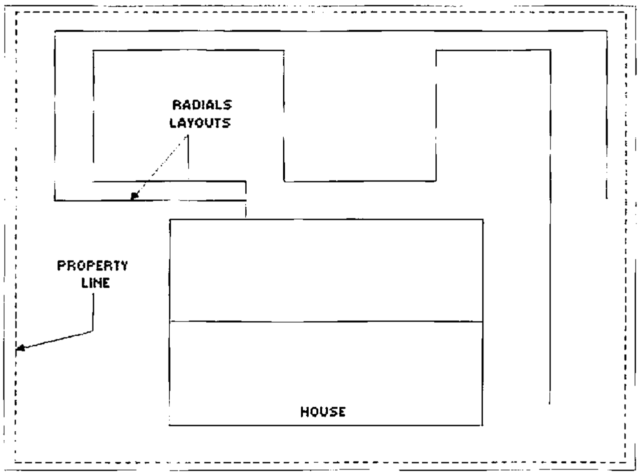

Fig. 4. *A straight radial configuration is preferable, but if you live on a small lot and don't have the space, use some variant of the two paths shown above.*

LETTERS

Continued from page 35

beginning—this from someone who has been fighting an uphill battle learning the code. I really enjoy sitting down practicing code with my SCS. I now have the way to not only learn the code for the test, but to enjoy using the code. Thanks, Wayne, for featuring this great unit in your magazine. Keep up the great work in bringing some really exciting things to us as you have with this unit. And thanks to Sam Ulbing N4UAU for inventing the Super CW Station.

Now don't you wish you'd saved your June '95 issue?... Wayne

Jim Thompson KC7APO. This letter is in response to "Dots and Dashes" by Hal Goodman W3UWH in the March issue. I've been a ham for just over two years. Like Mr. Goodman, my first few CW contacts were unforgettable. The day my license came in the mail it was hard to decide whether to fire up the Ramsey kit I had built or the Collins KWM2A I had picked up along the way. The coin came up tails so I turned on the Ramsey and it barely worked; just a problem with microphone mismatch, but the group on the 2 meter repeater helped me figure that out. After meeting several people and having a great time, I cleared and turned on the big radio. It took me a while to find a clear frequency and tune up for the first time (lucky I did not fry the finals!). I sent CQ on the 80 meter Novice band with a very shaky fist. After the second attempt, I began to wonder if I was getting out with only 100 watts. The third time, I got an answer from a fellow in Northern California. The QSO was brief, but it was my first CW contact and that does not happen very often (actually just once).

I was soon to meet many "Old-Timers" like Hal, who were very supportive and helpful. Much of what I know I learned from them and I am grateful. If I've ever said "thank you" to those guys, I probably can't say it strongly enough.

I quickly found out that learning the code was just the beginning. There are abbreviations, standard procedures, and phrases to learn that are barely covered in the books. That's fine; there's nothing wrong with the books. Just realize that, in many ways, the first ham ticket is just a "license to learn."

Much of my early copy looked like Hal's copy from Bill and, at first, I assumed that it was my faulty ears. I heard lots of characters that I couldn't identify or that never formed recognizable words. There was one time I thought I heard my name as "Wim." I listened carefully the next time and convinced myself that that was what he was actually sending. So I corrected him and he replied, "QSL Wim, got ya." I was learning.

Another time I turned it over and the fellow replied, "S" "O" then a pause and I thought, "Aha, a word." So I wrote down "so" and listened for the next. Then came "L, I, D" and I thought, "Aha, another word." So I wrote it down. Two words in a row! But then I began to wonder, "Wait a minute, is this guy calling me names? I'm new to this, but am I that bad?" The next word was of course, "COPY," but after that my self–confidence was so badly shaken that I copied little of what followed. Finally I realized that the guy was still sending and that I'd better get my pencil going. It ended up that he was really a friendly chap after all and the mistake was all mine. I copied all the characters just fine but of course there is more to it than that.

I listened carefully to the good counsel of these "Old-Timers" and learned lessons like: Don't send faster than you want to receive and don't be afraid to send PSE QRS. I also learned from the mistakes of others and strove to develop a good fist and operating habits. I started with a straight key, picked up paddles and found it all too easy to send those extra dits and dahs. I finally got a bug, learned to use it, and liked it. With the bug, I made far fewer mistakes than with paddles and was more relaxed than I was with a straight key.

The first step to good keying is to hear the sound of the character

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

This column marks the beginning of the 20th year of *RTTY Loop*. Twenty years is quite a milestone. Just look at what postage and interest rates have done over that time. Just look at interest in ham radio over that time! Overall, though, we're still doing OK. Because of the personal computer revolution, interest in digital communication has never been higher. Your letters and E-mail have shown me that. I am also aware, however, that any number of you feel that the old-timers are ignoring the fundamentals and basics when speaking to newbies. In this month's column, and the next several, I'll address that need.

We throw around terms and concepts as if they were common knowledge, forgetting that even the most seasoned among us once regarded the acronym AFSK as newspeak gobbledygook. My intent has always been to address the wide spectrum of amateurs interested in digital communications and computers. Having dealt with lots of cutting-edge questions of late, let's define some terms.

This month, I present a glossary for radioteletype and digital communication. Because there are those of us who are still using old paper printers, and those who are using fancy computer interfaces, this list will attempt to encompass terms used in both camps, with some others thrown in. If you have any additional vocabulary words you think should be included in the list, feel free to send them along. I'll keep an updated copy of this list on the RTTY Loop Home Page, for reference.

AFSK: Stands for Audio Frequency Shift Keying and is a means of encoding the digital information by changing the frequency of an audio tone.

AMTOR: Derived from a commercial mode, SITOR, Amateur Teletype Over Radio allows the receiving station to dynamically respond to errors from the sender.

ASCII: The American Standard Code for Information Interchange, this seven-bit scheme for encoding alphanumerics is the standard computer code used.

Baudot: A five-bit code which is used to encode the alphabet and numerics, through use of a shift into an alternate character set, this is the original Teletype code. Also called the Murray code.

"Many of you feel that old-timers are ignoring the fundamentals and basics when speaking to newbies."

Bias: With conventional digital signals, the state of the signal alternates between **MARK** and **SPACE,** with the length of pulses in either state the same. If the relative length of the pulses is unequal, the system is said to exhibit various kinds of bias.

Chad: When you punch a hole in a piece of paper, the plug that comes out is called a "chad." Paper tape, punched with many holes to serve as a memory device, generates tons of these chads.

Chadless: Obviously, without chads. If you want to type on the tape with the holes in it, the absence of paper where the holes are makes it difficult. Chadless tape leaves the plugs attached by little lips, to permit such typing.

CPU: Central Processing Unit, the brain of a computer. Common CPUs in home computers are Intel series 80386 and 80486, part of the x86 line, and Pentiums, as well as the Motorola 68000 series in the Macintosh computers.

Demod: Short for Demodulator, this is the electronic marvel that converts the warbling tones of radioteletype from a receiver into pulsed DC that a Teletype machine can interpret.

Fox Tape (or Key): There is a marvelous sentence that contains all the letters of the alphabet: THE

QUICK BROWN FOX JUMPS OVER THE LAZY YELLOW DOG. People frequently have a tape to send this for test purposes. Digital or computer setups may have this sentence reprogrammed at the touch of a key.

FSK: Stands for Frequency Shift Keying. Similar to AFSK, the frequency of a radio carrier is shifted to encode the digital information.

Governor: Not the person in your state capitol. Mechanical teleprinters are run by motors, and it is important for the motor to be turning at a precise speed. Older machines, or those intended for AC/DC work, used a governor on the motor to set the speed. A special tuning fork is used to set the motor speed.

Local Loop: If you hook all your equipment together so that anything you type on the keyboard prints on the printer, kind of like a big electric typewriter, that's a local loop—essential for testing.

MARK: Spelled differently than my first name, this is the state when everything is running quietly, and loop current is present. Could call it "1" if you're into logic.

Model 12, 14, 15, 28, 32, 33, 35, etc.: These are different series and styles of teleprinters and tape machines produced by the Teletype Corporation. The Model 15 is the classic keyboard and page printer on a table, seen so often in police and science fiction movies of the 1950s and 1960s. The Model 19 is the Model 15 with built-in Model 14 tape equipment. In general, the higher the number, the more recent the equipment manufacture.

Modem: A combination Modulator, for sending digital data, and Demodulator, for receiving. May be used for radio or telephone, for a variety of modes.

Packet: A scheme for sending digital data in discrete packets, which are acknowledged by the receiver after sending. Each packet can be addressed to a specific receiver or for wider distribution, making transmission more reliable.

Page Printer: If the teleprinter prints on a roll of paper which, when you tear it off, looks like a page, then it's a page printer.

Patch Panel: One of those can't-do-without things. Usually a jack strip which allows anything to be connected to anything (anything?).

Perforator: A keyboard connected to an electromagnetic device which punches tape as you type is a perforator. This cannot punch tape from an incoming signal.

Polar Relay: Normal spring-return relays take more energy to make than to hold. This would cause distortion in a digital signal, called bias. A polar relay uses two magnets, one to make and one to break, to overcome this problem. A bias (no relation) supply is needed for one of those windings.

RAM: The read-write memory populating home computers is commonly referred to as Random Access Memory, even though most memory boards, whether read-write or read-only, are random access.

Reperforator: A tape punch which decodes incoming signals and punches them into tape is a reperforator. Some versions type on the tape at the same time, and are called Typing Reperfs, of course, and are chadless.

RTTY: The ham's abbreviation for radioteletype.

RY: These two letters contain all the bits in the commonly used five-bit Baudot code. Therefore, repeating the letters, as RYRYRY, makes a good test signal.

SPACE: See also **MARK**. This is the state without loop current. Machines in such a state just shuttle back and forth making noise, called running open. This is the logical state "0."

Strip Printer: No, not what you're thinking; this is a printer which, unlike the page printer, prints its data on a narrow strip of paper, like a stock ticker.

Synch Motor: Since the motor for a teleprinter has to be a precise speed, it is nice to synchronize it to the 60 Hz line frequency. It takes the place of a governor motor.

TD: Stands for Transmitting Distributor, which is quite a mouthful, making the abbreviation convenient. This is a tape reader—so why couldn't they just say that?

TNC: Terminal Node Controller—the interface box used between the radio and terminal for packet mode communication.

TT, TTY: More abbreviations for **Teletype.**

Teletype: The whole ball of wax we are talking about. This is a trademark, however, of the Teletype Corporation, and should always be capitalized.

TU: Stands for Terminal Unit, and is the same thing as a Demodulator.

Once again, I welcome input to this list, both additions and corrections to my definitions. Send them to me via any of the means at the end of the column, and watch for updates on the RTTY Loop Home Page, at http://www2.ari.net/ajr/rtty. Also up there is the latest version of the RTTY Loop Software Collection, featuring over a dozen disks of data, along with old columns and links.

Several of you have been looking for the latest addition to Gary Johnson's XCOM software; check out the XCOM page at http://www.indirect.com/user/gjohnson for the latest and greatest, direct from the author.

As for me, reach me on the page, through the E-mail link, or at ajr@ari.net, or on America Online as MarcWA3AJR, or on CompuServe as 75036,2501. Or, if you have no other way, at the post office box above. Use that address, as well, for materials for the Software Collection.

I plan to continue the beginners' introduction next month, with a look at just why, and how, the alphabet can be encoded over a single wire circuit. Please feel free to send along comments, questions, or suggestions. I look forward to them!

Ham Radio Fun

Communications Simplified, Part 7

AM sidebands.

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Let's review a little. Awhile back, we learned that a square wave consists of a fundamental frequency and some harmonics. We made a rather sweeping statement that any repetitive waveform can be broken down into a fundamental and/or some harmonics.

Let's start this segment off by putting down a general rule, and then we will explain it: *When a carrier with frequency C is modulated by an audio (or other) signal having frequency A, we get two sidebands, whose frequencies are C+A and C-A. Moreover, at 100% modulation, the two sidebands are exactly one-half the size of the carrier.*

Let's consider an example. Suppose an AM radio station at 880 kHz transmits a carrier whose amplitude is 100 volts when there is no modulation (that is, when there is no sound being transmitted). If you looked at this signal with a spectrum analyzer, you'd see just a carrier, as shown in **Fig. 1**.

Now suppose the announcer steps up to the mike and whistles a 1 kHz note into it, loud enough to produce exactly 100% modulation. If you looked at the transmitter output with an oscilloscope, you would see a 880 kHz carrier, whose envelope goes up and down at a 1 kHz rate, but if you looked at that same signal with a spectrum analyzer, you'd see the picture shown in **Fig. 2**. You would still see the same 100 volt carrier at 880 kHz *(which never changed amplitude)*, plus a 50 volt signal (called an *upper sideband*) at 881 kHz (881 is 880 plus 1 kHz), and another 50 volt signal (called a *lower sideband*) at 879 kHz.

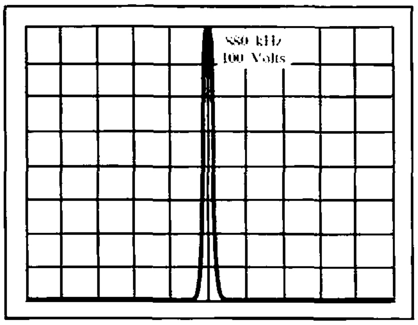

Fig. 1. An unmodulated carrier at 880 kHz.

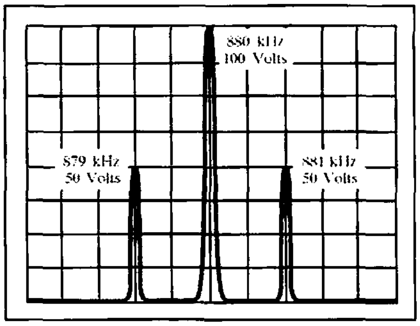

Fig. 2. 880 kHz carrier modulated 100% by 1 kHz.

So what's really happening is that the radio station is generating a 880 kHz carrier, and then AM modulating it (changing its amplitude) at a 1 kHz rate. On the air, we actually have an 880 kHz carrier which has a constant amplitude, plus two extra signals called sidebands. These sidebands also have a constant amplitude, but when we see the combined signal on an oscilloscope, all three of these interact together to make it *look* as though the carrier is changing height.

Fig. 3 shows how this is possible. This is a computer-generated graph, which shows three sine waves at the top, and their sum on the bottom. The bottom waveform is simply the point-by-point sum of the top three waves. At the far left and far right, the three top waves are pretty much in phase, and so they add up to a big result. In the middle, however, the two sidebands are out of phase with the unmodulated carrier, and so they cancel it out to produce a very small result.

DETOUR

Here's the BASIC program which draws the same waveforms as in **Fig. 3**:

```
10 'Generate AM from sidebands
20 SCREEN 2
30 FOR X=0 TO 639
40 CARRIER=SIN(X/10.185616#)
50 UPPER=.5*SIN(X/10.185616#*1.1)
60 LOWER=.5*SIN(X/10.185616#*.9)
70 AM=CARRIER+UPPER+LOWER
80 PSET(X,20-20*CARRIER)
90 PSET(X,60-20*UPPER)
100 PSET(X,90-20*LOWER)
110 PSET(X,150-20*AM)
120 NEXT X
130 IF INKEY$="" THEN 130
140 SCREEN 0
```

END OF DETOUR

Look at **Fig. 3** some more. Suppose this graph covers exactly one second of time. Since the unmodulated carrier on top has exactly 10 cycles, its frequency is exactly 10 cycles per second, or 10 Hz. It's a little harder to count the cycles of the AM signal on the bottom, but it too has exactly 10 cycles, and therefore is also exactly 10 Hz. Now look at the envelope of the AM signal; draw it in, if that will help. The envelope starts big, goes to small in the middle, and then becomes big again, so it has exactly one cycle during that second, and is therefore at 1 Hz. So we have a 10 Hz carrier, modulated by 1 Hz. (These frequencies are not exactly practical for real radio, but they are nice simple numbers, and easy to visualize.) According to our

previous discussion, the two sidebands should therefore have frequencies of 11 and 9 Hz (which is 10+1 and 10-1).

Sure enough, if you count the cycles of the two sidebands, you can see that the upper sideband has 11 cycles, while the lower sideband has only nine cycles. Their frequencies are therefore 11 Hz and 9 Hz, respectively.

Note also that the AM signal is modulated to 100%—you can see that its amplitude goes all the way to zero. You can also see that the two sidebands are each exactly one half the size of the unmodulated carrier.

Let's go back to the 880 kHz transmitter example (refer to Part 6, in the June 1996 issue of *73*, if necessary). The carrier voltage V_c is 100 volts. When the two 50 volt sidebands are in phase with the carrier, all the voltages will add up to a V_{max} of 100 + 50 + 50, or 200 volts. On the other hand, when the two sidebands are out of phase with the carrier (look at the center portion of **Fig. 3** to see how this happens), they all subtract to give us a V_{min} of 100 - 50 - 50, or 0 volts.

So we now have two ways of determining the percentage of modulation of an AM station: Look at it on the oscilloscope, or look at it on the spectrum analyzer. For example, what is the modulation percentage for the signal in **Fig. 4**?

Let's see, the carrier has a height of about 6.4 divisions. Since we can't see the knobs on the analyzer, we don't know how many volts that is, but that doesn't matter; 6.4 divisions is good enough for us. If that signal were 100% modulated, then the sidebands should be half of 6.4, or 3.2 divisions, but they are only about 1.7 divisions high. So the modulation is only 1.7/3.2 of its maximum. That works out to:

$$\frac{1.7}{3.2} \times 100\% = 53\%$$

So far, so good. Now that we've gotten so good at this, let's look at a *real* AM broadcast station on the analyzer and try to figure out what their percentage of modulation is. It's actually quite easy; we just have to throw some wire out the window and connect it to the analyzer's input, and we get **Fig. 5**. We still see a nice carrier, but on each side we now see just plain fuzz, rather than a neat sideband. What's going on?

The difference is that the real station isn't broadcasting just plain tones—their audio consists of music and speech. This includes many different frequencies, all at different amplitudes but at the same time. Every single frequency in the audio generates its own pair of sidebands. So we have many sidebands, all occurring at the same time, and all constantly changing as the music or voice changes. The result? A fuzz that actually extends past the edges of the analyzer picture.

To avoid confusion, some people use the term *side frequency* when they describe the sideband from a single tone, as in **Fig. 4**. They would then say that all of these different side *frequencies* combine to make the two side*bands* in **Fig. 5**, a lower sideband to the left of the carrier, and an upper sideband to the right.

Bandwidth

Our simple example with the announcer whistling at 1,000 Hz showed that the radio signal would consist not just of the carrier at 880 kHz, but also of sidebands (side frequencies) at 879 and 881 kHz, 1 kHz away from the carrier on each side. AM broadcast stations normally transmit voice or speech with a frequency range of about 50 to about 10,000 Hz—not quite hi-fi, but still higher than just 1 kHz, and since the side frequencies lie at the carrier frequency plus and minus the audio frequency, we will now have side frequencies that lie anywhere from 50 Hz to 10,000 Hz away from the 880 kHz carrier. In other words, the sidebands will extend 10 kHz out from the carrier in both directions, down to 870 kHz on the left, and up to 890 kHz on the right.

The complete radio signal will, therefore, take up 20 kHz of space on the band (from 870 to 890 kHz), and so we say that the bandwidth of the AM signal is 20 kHz. We can summarize it this way: *The bandwidth of an AM signal is twice the highest audio frequency being transmitted.*

The bandwidth is related to how close stations can be placed to each other on the dial; the wider the bandwidth, the farther apart they have to be. To limit the bandwidth of commercial broadcast stations, the FCC limits their audio frequency range to a maximum of 10 kHz, which sets the maximum bandwidth at 20 kHz. Actually, though, AM broadcast stations are placed farther apart than their bandwidth would indicate, because the tuned circuits in most radios are not good enough to separate stations that are too close together. For example, in the New York City metropolitan area, stations are typically 50 or 60 kHz apart.

Sideband power

When a transmitter sends out sidebands, it needs power to do that. Let's consider a commercial AM broadcast station which sends out a 5 kW carrier. If the cable leading from the transmitter to the antenna has an impedance of 50 ohms, then we can find the output voltage by solving the power equation $P = V^2/R$ backward for the voltage:

$$V = \sqrt{P \times R} = \sqrt{5000 \text{ watts} \times 50 \text{ ohms}} = 500 \text{ volts}$$

When the station modulates that carrier at 100%, it still sends out a 5 kW (500 volt) carrier, but now it also sends out two 250 volt sidebands.

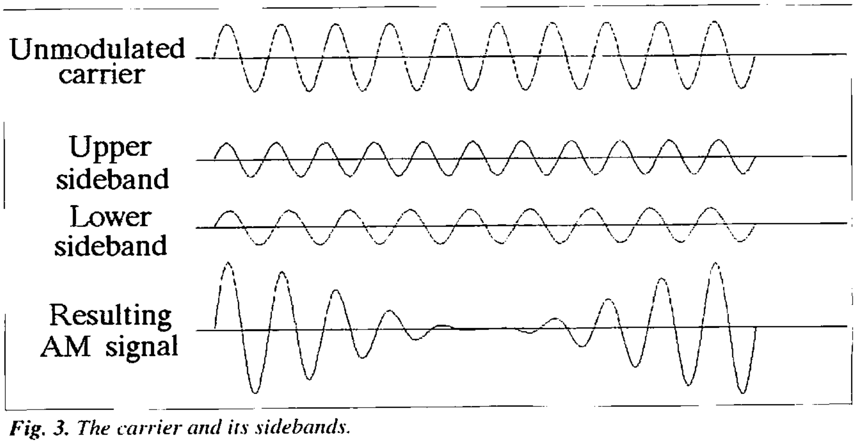

Fig. 3. The carrier and its sidebands.

Each of those also goes into the 50 ohm cable, so the power in each sideband is

$$P = \frac{V2}{R} = \frac{250^2}{50} = 1{,}250 \text{ watts}$$

The transmitter is now putting out 5,000 watts into the carrier, plus another 2,500 watts into the two sidebands, for a total of 7,500 watts.

Efficiency

The amount of sideband power depends, of course, on the modulation percentage. From the $P = V^2/R$ equation, we see that the power is proportional to the square of the voltage. Thus, cutting the modulation down to 50%, for example, drops the sideband voltage to 1/2 of the 100% value, and so drops the sideband power to 1/4. Cutting the modulation percentage to 10% would drop the sideband voltage to 1/10, and the sideband power to 1/100. So in normal speech or classical music, where the volume is seldom at its maximum, the modulation percentage and sideband power tend to be much smaller than the carrier power. On the other hand, in modern popular music, where it seems like everybody is constantly yelling and screaming (to my jaded ears, anyway), the average modulation percentage would be higher, and the sideband power also.

In any case, we now know that the carrier in an AM signal never changes; only the sidebands change, depending on the signal being sent. We also know that the carrier contains most of the power of the AM signal. But is it really needed?

If the carrier never changes, then it doesn't carry any information to the receiver. By the time it gets to the receiver, it is just a weak sine wave. In fact, if the transmitter somehow turned the carrier off (sending only the sidebands), and the receiver had a circuit which generated a substitute sine wave of the right frequency, amplitude, and phase, it would never know the difference. But generating a weak sine wave at the receiver is a lot cheaper than generating a high power carrier at the transmitter.

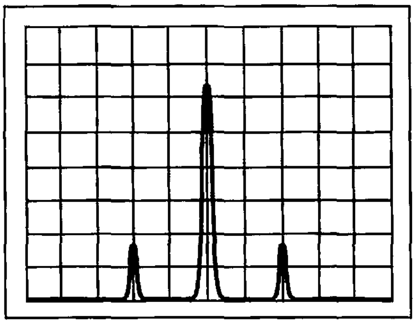

Fig. 4. What is the modulation percentage?

This is the basic idea behind several variations on AM; changes which make both the transmitter and receiver somewhat more complex, but which greatly increase the efficiency of the system by reducing the transmitter power. These two major methods are called double sideband (DSB) and single sideband (SSB).

Double sideband

DSB is also sometimes called DSSC, which stands for double sideband suppressed carrier, a name that describes it well. In DSB, the transmitter sends out only the two sidebands and eliminates the carrier, which is then reinserted by the receiver.

Although the transmitter could produce regular AM and then filter out the carrier, this approach would waste power. A better approach is to use a *balanced mixer* to produce the DSB directly. In the balanced mixer, two AM signals are produced at low power, and then combined in such a way that the carrier gets canceled out.

The major advantage of DSB is efficiency. Consider, for instance, the 5,000 watt AM transmitter we discussed a moment ago. At 100% modulation, the transmitter would have to add 2,500 more watts for the two sidebands, for a total power output of 7,500 watts. On the average, considering typical voice or music, the sidebands might only contain a total of 1,000 watts or so, but the transmitter must still output the carrier. So its average output power might be closer to 6,000 watts. If it could eliminate the carrier, then it would need only to output an average 1,000 watts or so for the same sideband strength, and the resulting signal would travel just as far.

Alternatively, if you didn't mind spending the money, you could put all 6,000 watts into the sidebands, and get the same punch as if you had an AM transmitter of perhaps 20,000 watts or more. There would be still another advantage, too: When two signals are close together in frequency, they interfere with each other and it turns out that most of the interference is between the carriers, not between the sidebands, so eliminating the carriers would eliminate much of the interference. In fact, during silent passages there is no interference at all since the sidebands are only there when there is something being transmitted.

By now you're asking, "If DSB is so wonderful, why doesn't everyone use it?" There are two answers to that: (1) It has some disadvantages, and (2) there's something even better.

One disadvantage is that it makes the receiver more complicated. In commercial broadcasting, the philosophy has always been to make the receivers as cheap as possible so everyone can afford one, even if that makes things more expensive for the broadcasters. DSB doesn't fit into that pattern.

A second problem is that inserting a fake carrier in the receiver is not that difficult, but making sure that it is just the right frequency and amplitude is tricky. Putting it at the wrong frequency is the same as putting the sidebands in the wrong place; if the frequency difference between the carrier and the sidebands is wrong, the frequency of the audio will be wrong too. Even a slight difference, on the order of a small fraction of a percent, can make voices sound funny, and make music inaudible.

So DSB would be okay for voice communications, but not really for music. (There are some places where it is used for music, as in stereo FM, but that's a special case, because some extra circuitry is used there to help the receiver put the carrier in the right place). For strictly voice communications, there is something even better: SSB.

Single sideband

If you look at any of the spectrum analyzer pictures of AM (**Figs. 2** or **5**), you will note that the lower sideband is

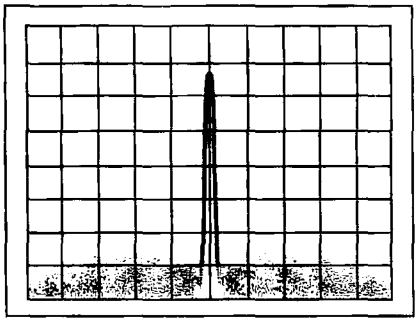

Fig. 5. An actual broadcast station.

always the mirror image of the upper sideband. For every side frequency component in the lower sideband, there is also a matching side frequency component in the upper sideband. So why does the receiver need both sidebands? It doesn't.

As long as the receiver gets one sideband, it gets all the information there is. It's sort of like you mailing a letter to a friend, but putting a second copy of the letter into the same envelope just in case. That second copy doesn't really tell your friend anything new. Unless the first copy gets damaged, of course, but in that case the second copy probably will too.

That is the idea behind SSB. With it, the transmitter sends only one sideband—no carrier, no second sideband. There are two ways to do that. One way is to generate a DSB signal, but then filter out one of the sidebands; the other is to generate two DSB signals in such a way that adding them cancels out one of the sidebands because it is out of phase in the two signals.

Let's look at the advantages of SSB:

1. It's much more efficient than plain AM, and even twice as efficient as DSB. No output power at all when there is no audio.

2. It causes even less interference to other stations than DSB, which also has no carrier.

3. It's half the bandwidth of AM or DSB. Remember that the bandwidth of an AM signal is twice the highest frequency being sent. For example, a telephone-quality signal with audio from 300 to 3,000 Hz would have an AM or DSB bandwidth of 6,000 Hz. With SSB, on the other hand, the bandwidth is only 2,700 Hz (since that is the frequency difference between the side frequency caused by a 300 Hz signal and the side frequency caused by a 3,000 Hz signal).

The bandwidth is important for several reasons. First, it means that twice as many stations can be crammed into the same band as AM or DSB (actually, more than twice, because there is so much less interference between them). Equally important is the fact that the receiver can now have tighter filters, which can do a better job rejecting other noise. The noise power picked up by a receiver is proportional to the bandwidth; cutting the bandwidth in half cuts the noise power in half too.

What about the disadvantages? The major one is that it is even more difficult for the receiver to decide where to put its fake carrier. With DSB, at least the receiver can simply put the carrier exactly midway between the sidebands. With SSB, there is no midpoint. In fact, unless the user knows whether the transmitter is sending the upper sideband or the lower sideband, the receiver may not even know which side of the sideband to put the carrier on.

Tuning in an SSB signal is difficult. Even very expensive receivers require the user to adjust the tuning until "it sounds right." That may be close enough for voice, but useless for music. Hence, SSB is used only for radio voice communications, never for music (although SSB is used for certain wire-line communications with better results, but there again there are special tricks used to give the receiver additional information to help it generate the right carrier).

Vestigial sideband

As we mentioned in an earlier installment, the bandwidth of the composite video signal in a TV is approximately 4 MHz. Since AM is used for transmitting the picture in commercial TV, modulating this composite video signal onto a carrier would normally result in an 8 MHz bandwidth (twice the highest frequency in the picture), but TV stations are only allowed 6 MHz bandwidth (and some of that has to be used for the sound carrier).

The solution used for TV is *vestigial sideband*. The word vestige means leftover or remainder. TV transmitters transmit the entire upper sideband, but only a part (the "vestige") of the lower sideband.

For example, TV's channel 2 occupies frequencies from 54 to 60 MHz. The picture carrier is at 55.25 MHz; the upper sideband goes from 55.25 to 59.25 MHz, the full 4 MHz, while the lower sideband goes from 55.25 MHz down to 54 MHz, just 1.25 MHz. Even though most of the lower sideband is missing, the upper sideband contains all the information that the TV needs to properly receive the picture. We should mention that the top part of the 6 MHz channel is used for the sound signal, which has a carrier at 59.75 MHz, but this part is sent as FM (or frequency modulation), so we will leave that discussion for later. For now,

DETOUR

Here's an interesting calculation you can do yourself.

We've already said that, when an AM carrier is modulated 100%, each sideband is 1/4 the power of the carrier. With two sidebands, that increases the power by 1/2. Here is how to check that.

Fig. 6 shows 10 cycles (20 half-cycles) of a 1 volt unmodulated carrier on the left, followed by 10 cycles (20 half-cycles) of a carrier modulated 100% on the right. Since the formula for power is $P = V^2/R$, the power is proportional to the square of the voltage. So let's square the voltage of each half-cycle of the unmodulated carrier on the left, and add up all the squares to get some idea of the relative power (ignore the units). Each half-cycle is 1 volt, whose square is also 1. For 20 identical half-cycles, the sum is 20.

Now repeat the same for each half-cycle of the modulated carrier. For example, the shaded half-cycle has a height of about 1.2 volts, so its square is about 1.44. Repeat that calculation for each of the 20 half-cycles (some are so tiny they are hard to see) and add up. You should get a sum of about 30, which is 1/2 more than 20.

This calculation shows that the total power of an AM signal increases by 50% when it is fully modulated. As we explained before, this extra power all goes into the two sidebands.

END OF DETOUR

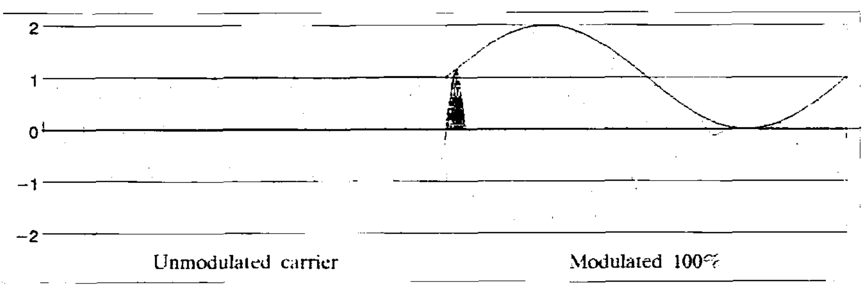

Fig. 6. Calculating the power of a 100% modulated carrier.

it's just important to mention that the TV picture and sound carriers are purposely different so that they cause as little interference with each other as possible.

Conclusion

Amplitude modulation is used in a number of important places. Commercial AM broadcasting uses it, of course, but so does TV (although with a vestigial sideband). It's also used in the aircraft band, and by international broadcasters on the shortwave bands.

In amateur radio and other point-to-point communications, however, AM has been replaced by other modulation methods. SSB is important, but so is FM and various digital pulse methods (both will be discussed in future installments of this series).

NEVER SAY DIE

Continued from page 39

Imagine, convincing people to spell the words the way they sound! Impossible, of course. Yet, anyone who's done much CW work is used to abbreviated spelling, so this just might present some fertile ground to start the change. Fb om es cul, right?

The booklet is available from Radio Bookshop for $5 postpaid in the US and Canada. For foreign mailing please add $1.

If you know people who teach school you might get them to try Ray's ideas out on their kids and see what they think. Lemeno.

Math Problem

A fax arrived from Irwin Math WA2NDM, who writes a column for *CQ*. He was worried that some careless souls might hop into the Happy Hunting Ground via the Bioelectrifier described in the May *73* via passing the current through their hearts. In my AIDS booklet I do stress the importance of *not* passing the 50 µA from arm to arm. Yes, I know, a lot of experimenters have done it and none have, as far as I know, done themselves in. But why take chances?

The article says to pass the current from one ankle artery to the other. Bob Beck called to say *not* to use any metal around the ankles, as the author did. That can give burns. He says to use an inch or so of solid bare wire wrapped in flannel and tied in place with a silk thread. Then soak it in a saltwater solution.

On the other hand, since any experimenting on live people must be done by a doctor, presumably the doctor will know better than to zap the heart. But then they have a license to kill, so one never knows.

I wanted to reassure Math that the base was covered, but he forgot to put an address or fax number on his fax, so I looked into *CQ* for his address. None given there either. But while I was looking for his column, which was indexed to be on page 86 (I finally found it on page 40), I couldn't help but notice that most of the magazine was devoted to columns. I counted 9-2/3 pages of feature articles and reviews, and the rest of the 134-page magazine was devoted to columns and ads. From page 34 onward it was all columns! Only one of the articles was construction oriented—a simple antenna switch. Say, I wonder when editor K2EEK is going to get his General ticket and join us on the low bands?

One of the reasons I got fired as the editor of *CQ* after five years at the helm was my insistence on publishing construction projects. Speaking of which, I counted 26 pages of feature articles and reviews in *our* May issue.

Getting back to the Bioelectrifier, getting viruses and other crud out of the blood is beneficial, but with HIV you also have to chase it out of the lymph glands, where it can hide for years. Beck has a simple system for doing this. He wound a small coil, about 150 turns on an old VCR spool, and put it in series with a flash-gun bulb. This provides a short blast of about 20,000 gauss, which Beck says knocks the virus out of the lymph gland and into the blood stream, where a Bioelectrifier can keep it from attaching to the white cells.

At the Tampa Global Sciences Congress, Beck also reported that he'd been using the coil-flash unit on his head and, as a result, was sporting a new head of hair. Beck, by the way, has the original patents on flash guns. Let's see, I wonder how much an old flash gun is going for at flea markets now?

If that also counts as a medical procedure, then it should be done under a doctor's care. I dunno. I'm just reporting what I've seen and heard. But if you have a heart pacer, I hope you won't be dumb enough to jump-stop it with the coil.

If you'd like to hear Beck's fascinating one-hour talk for yourself, it's available for $10 from Radio Bookshop as item BB-1.

The Numbers

The latest FCC count from Gettysburg tells the story. Let's compare the number of General, Advanced, and Extra Class licensees between 1982 and 1996; 14 years, 320,249 - 242,583 = 77,666 gain. That's a 2.3% gain per year in 14 years. Less than a three percent growth for 14 years! Heck, we're probably dying faster than that! Those figures count nine years of dead hams, plus nine years of who knows how many dropouts who won't bother to renew.

Yes, the Novice and Techs have grown from 164,866 to 393,322 in the last 10 years, for an average growth of 13.9% per year! And almost all of 'em are still up there on 2m. Maybe you can figure some way to get 'em Generalized and down on our HF bands. I tried hard with *Radio Fun* and I failed to make a dent. Since the written exams are so easy to memorize, it has to be the dreaded code that's gradually killing our hobby.

Are the Techs coming to your club meetings? If not, why not?

You're probably right. I should shut up about this and let what's going to happen, happen. Heck, I don't even know how to motivate people to stop killing themselves and their families with poisons and poor nutrition.

HAARP News

Unless you've been living in a cave somewhere, you're at least somewhat aware of all the fuss over the government's multi-megawatt plans to blow holes in the ionosphere with an Alaskan research project called HAARP. Nick Begich, whom I met at the Tampa Global Sciences conference in January, is the author of *Angels Don't Play This HAARP: Advances In Tesla Technology*.

A letter from author Fred Jueneman (I reviewed his *Raptures of the Deep* for you) had an interesting comment on the project. "If HAARP, in its wildest dreams, does succeed in short-circuiting the ionosphere to the surface of the Earth, or by some extension of the same principle, short-circuit the Van Allen Belt with its four million ampere current, this might momentarily negate the Earth's magnetic field, resulting in an effect known as the Giauque-Debye adiabatic demagnetization—a technical mouthful meaning that with the precipitous loss of a magnetic field an extreme cooling results. If HAARP somehow manages to short-circuit the Van Allen Belt, this effect is what I anticipate would occur. The results are so much more devastating in magnitude that they would make any thoughts of the destruction of the ozone layer pale in comparison.

"I'd expect that such a massive electrical discharge would make the ionosphere flare up like a multi-colored fluorescent display, sending spectacular streamers throughout the upper atmosphere. What could happen next with the almost instantaneous cooling of the polar air is the precipitation of the atmosphere itself like snowflakes in a blizzard over a rather sizable area. This adiabatic effect could create an equally sizable vacuum that would be filled by onrushing atmospheric air from the more temperate regions of the Earth's surface, generating winds of tornadic force which would level everything in their paths.

The wideband FM Gunn transceiver

Gunn oscillators and wideband FM for communications were covered in detail in the April 1990 issue of this column in *73*. I have received many requests for information on how to set up a simple Gunn system, so I will cover part of that information again.

Why use a simple Gunn diode oscillator for microwave communications? Well, what the Gunn diode oscillator system has going for it is that it's a low cost method of getting into microwave operations. I'm happy to comply with readers' requests—for those interested in microwave operation, 10 GHz FM provides the easiest minimal cost system to put together. The equipment that will be described here functions very well and is capable of commercial-sounding full-duplex audio. I have to apologize for skipping this simple mode of operation as I have moved on to more costly and complex SSB communications schemes. Let's go back to my roots on 10 GHz.

Scrounge yourself a simple transceiver

In the beginning, all microwave components were not created equal, and their prices were high, keeping many amateurs from obtaining them. That prevented many amateurs from investigating operation on our microwave bands. Amateurs being what they are, avid scroungers soon broke the price barrier ($10 to $15 each), noting that a simple Gunn oscillator from a burglar alarm unit could function in a 10 GHz WBFM communications system.

This unit is a simple form of the very popular Gunnplexer™ from Microwave Associates, the premiere WBFM transceiver. Most of the component parts for this simple version can be scrounged, and it can be assembled at home. (Of course, if you want the best and easiest WBFM operation, purchase a Gunnplexer from M/A: these units are costly, but they function perfectly.)

Bits and pieces can be obtained through diligence and the constant combing of local resources. (*Caveat*: This information might not be as timely as it was several years ago when material was more plentiful.) Where do you find transceivers? Look in your own back yard: in the burglar alarm, garage door opener, and shopping center supermarket door opener industries. A lot of these devices are microwave, operating at 10525 MHz in the common use frequency band. This frequency is just above our 10 GHz amateur band and these devices can be adjusted down into our band very easily. Just increase (in most cases) the penetration of the frequency tuning screw into the cavity to lower frequency to WBFM frequencies of approximately 10250 MHz.

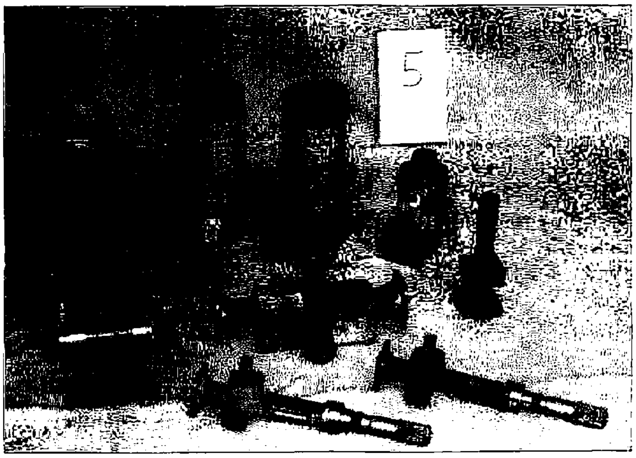

Photo A. Cavity wave meters (frequency meters) suitable for measurement at 10 GHz. The devices in the front row are slide-screw tuners, detector mounts and a sliding short for waveguide analysis.

"For those interested in microwave operation, 10 GHz provides the easiest minimum-cost system to put together."

If you go to suppliers or alarm companies, tell them you are looking for the metallic microwave units and are not interested in reusing them for alarm purposes. If they still have some of these units in their junk rooms, this strategy will usually work. If not, units can still be purchased from various sources and swap meets for a reasonable cost (not over $20 for a working cavity). New cavities from alarm company suppliers might go up to the $35 or so price range.

Most of these cavities employ a Gunn diode and a detector diode within the same cavity arrangement. Usually the Gunn diode is isolated in the rear and the detector diode is forward-mounted in the open end of the waveguide. The Gunn diode is fed from a power supply modulator circuit which reduces a 12- to 14-volt source to a regulated (variable) output voltage of 7 to 10 volts. The "adjust" terminal of the power supply regulator is modulated with a small AC voltage from an audio amplifier which is microphone-driven.

The mike amplifier is capacitively coupled to the adjust terminal of the regulator (an LM-317 variable voltage regulator). This regulator is preset to a voltage between 7 and 10 volts for proper Gunn operation. When you vary the voltage regulator's adjust pot, the Gunn's voltage will vary and so, slightly, will the frequency of the Gunn oscillator. With the adjust pot, it's just a slow frequency change that might be plus or minus 3 to 5 MHz or so. This is the fine frequency control for the simple Gunn oscillator. The M/A Gunnplexer uses a varactor frequency control, making for far superior control and frequency adjustment.

FM modulation is the very rapid changes (AC audio impressed on the adjust terminal) causing the audio voltage changes to frequency modulate the voltage regulator voltage setting, and, thereby, the carrier frequency. The audio changes are transparent to the adjust terminals fine control. It's like two signals riding the same control, one fast (modulation) and one slow (fine frequency adjust of the DC voltage output).

The minute audio voltage changes control the FM deviation of your oscillator. These millivolt changes (AC) cause the voltage regulator's output voltage to vary accordingly, slightly up or down. This depends on the waveform being positive or negative at a particular instant. Positive adds to, and negative subtracts from, the overall output voltage. Its effect is to reproduce your speech (voltage changes) on the Gunn diode, producing frequency modulation. The exact level of the audio driving the regulator sets the deviation and is somewhere around 50 to 100 kHz wide bandwidth, producing commercial sounding audio. That's why it is called WBFM, wideband FM.

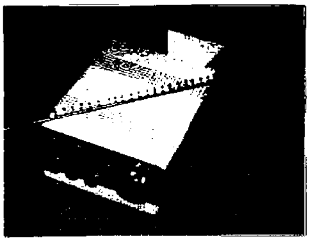

***Photo B.** The antenna on top of the rig is a 40-element loop yagi for 10 GHz. It measured 15.5 dBi at the Central States VHF Antenna Contest. (Photo courtesy of Kent WA5VJB.)*

Not too bad, considering the minimum parts count to produce a microwave transmitter circuit with voice modulation. You have only used a Gunn diode in a cavity, an op amp and one voltage regulator. For now it's sufficient to say that the Gunn diode is oscillating on some frequency in the 10 GHz range. To set the frequency, a waveguide frequency meter is perfectly suited as its accuracy (plus or minus a few MHz) is sufficient for WBFM operation. (Note: A wavemeter is not suitable for narrowband SSB or narrowband FM operation. Narrowband FM is what is generated by a VHF HT.)

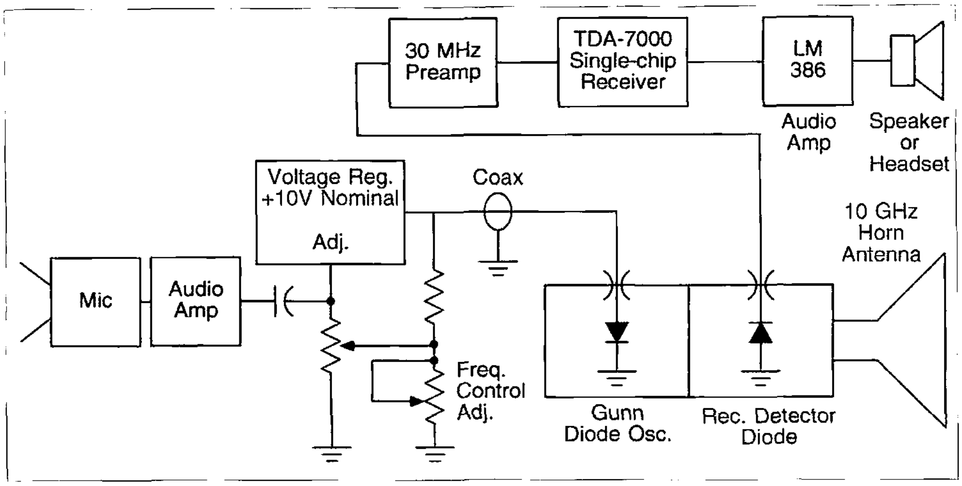

Fig. 1. Block diagram for a 10 GHz wideband FM Gunn transceiver.

A frequency counter is required for SSB/FM narrowband operation due to the more exacting frequency requirements imposed on narrowband operation. In trying to contrast these two modes of operation, I like to envision WBFM looking for a detectable signal in 250 kHz or 1/4 MHz bites as opposed to looking for a similar narrowband FM or SSB signal in 2 kHz bites, which is some 100-200 times more critical in terms of frequency bandwidth.

"Our Microwave Group in San Diego was founded on the use of WBFM and simple Gunn transceivers; the cost was minimal, and it got about 20 to 25 people on the air."

The receiver circuit

The receiver circuit is not quite as simple as the transmitter described above. The receiver consists of a detector diode in the front end of the Gunn diode cavity structure, normally coupled to a 30 MHz RF preamplifier to amplify the small signal recovered from the detector diode (mixer) and pass it on to the main IF amplifier/audio amplifier circuit. The IF amplifier that I used is a complete FM radio receiver (IF amplifier in this case) on a single 16-pin chip (Signetics TDA-7000). It is capable of operation up to 120 MHz. We have determined that an IF of 30 MHz is quite satisfactory and is becoming a standard for WBFM operation on the microwave bands.

The TDA-7000 chip IF amplifier that I used is capable of detecting a signal of 10 microvolts and producing a full quieting audio output. Coupling it with a simple single-stage RF amplifier, such as a 40673 MOSFET or a U-310 JFET amplifier, will improve sensitivity to a fat tenths-of-a-microvolt or so.

The complete schematic of the circuit (**Fig. 1**) shows how simple it is. Basically, the circuit is a free-running L/C-controlled oscillator operating on a low frequency of 70 kHz (internal to the TDA-7000 chip). The coil and capacitor that determine frequency are set to resonate at 30 MHz. I used a 1.8-inch shielded miniature slug-tuned core to wind 12 to 13 turns or #20 gauge enameled wire for the main oscillator coil. Add capacitance to tune to 30 MHz with the core adjustment and capacitor value. The exact capacitor value will vary due to coil "Q" and exact size and construction techniques. This is not exact, so a fudge factor is appropriate here.

We use 30 MHz as our IF frequency, which is produced by mixing two different signals—the same as in any receiver. However, when you look at **Fig. 1**, you'll notice that there isn't a separate local oscillator to mix with the incoming received signal, as you might expect. In this receiver the local oscillator signal is actually provided by the transmitter itself. As long as the two transmitters are offset by 30 MHz each transmitter can also act as the receiver's local oscillator, producing a 30 MHz IF signal to feed to the TDA-7000.

Here's how it works. Unit #1 sets his transmit frequency to 10250 MHz, and Unit #2 sets his transmitter 30 MHz to either side of Unit #1's—let's say 10280 MHz. Back at Unit #1, the 10280 MHz signal from Unit #2 is being received in the horn antenna. This signal mixes with some of the 10250 MHz being transmitted out of the Unit #1 dish, and produces a 30 MHz difference frequency. (The receiver detector diode is actually acting as a mixer.) This difference frequency is processed by the TDA-7000 as an IF frequency and demodulated. On the other side of the link, Unit #2 is still transmitting on 10280 MHz. He receives the 10250 MHz signal from Unit #1, which mixes with his transmitter frequency. This produces a 30 MHz difference frequency in his feedhorn, which gets passed to his receiver circuit. As long as the two stations are offset by 30 MHz—one high, and one low-full-duplex conversations can take place.

Now, don't be gullible—this is not all rosy. The operation is true and works, but there are some small hitches to this mode of operation.

First, you have to have some test equipment to set frequency. even though the frequency is a very wideband FM mode of operation. It will be somewhat frustrating trying to keep a free-running Gunn oscillator near the 100 kHz or so band widths of simple burglar alarm type cavities that exhibit limited electrical frequency tuning. More expensive cavities solve this deficiency by placing a varactor to adjust the cavity frequency about 60 to 80 MHz, making frequency adjustment a very simple manner. But,

Photo C. Jack N6XQ on Mt. Soledad assembling his WBFM M/A rig on his 30-inch dish. This is a popular spot in San Diego for contacts to Mexico, Los Angeles and beyond as it's an almost all over-the-water shot. I have observed microwave ducting from this location many times.

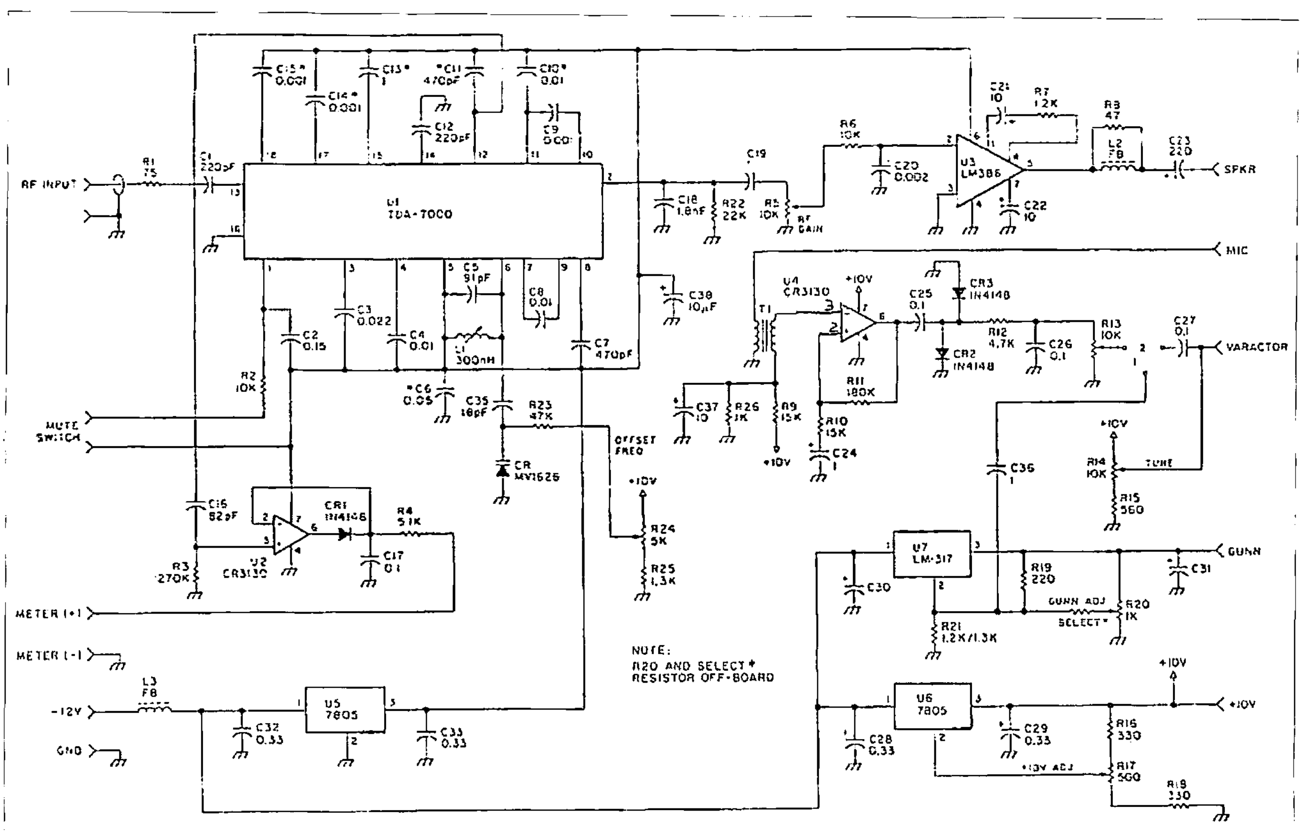

Fig. 2. Schematic for a 30 MHz IF power supply and transmit modulator control circuitry for a complete 10 GHz communications system.

as in the difference between a Chevy and a Caddy, price looms as the great separator.

If you are asking yourself what basic system you want to play with for microwave, I suggest you get the Chevy. For all its faults, it will not bankrupt you and, for a limited output of cash, it will let you test the microwave waters. This column is intended to provide you with a guide to a circuit that works. It is by no means the last word, but rather a starting place for inexpensive experimentation.

Sure, there are much better modes of operation, and far more sophisticated circuitry will blow the doors off this project, but then there goes the Caddy vs. Chevy talk. That discussion can go on to time's end. The real end to the discussion is what you want to accomplish. If you want to get your feet wet and test the waters, try this approach. If it doesn't meet your needs, go on to another fishing hole or try another microwave frequency band.

Our Microwave Group in San Diego was founded on the use of WBFM and simple Gunn transceivers: the cost was minimal, and it got about 20 to 25 people on the air. Our use of WBFM lasted for several years and produced some very amazing contacts. We became quite proficient in operation and new improved methods. Simple things like "Where is north?" and "I mean *that-a-way*" are not accurate enough for pointing a dish antenna at microwave frequencies. Accurate pointing has to be dealt with when you want to remove pointing errors and make microwave contacts.

PC board available

There are several things that need to be addressed in this arena and will be dealt with in next month's column. Let's wrap up the receiver construction and get this project on the road. I am told that I can replenish my stock of TDA-7000 chips if I order 100 devices. I am placing an order as this is being typed and will have PC boards and data with the TDA-7000 chips available for $12.50 postpaid to US destinations. I will toss in some capacitors (tantalum) and a few other parts that I have on hand to assist you in the parts count (this is a freebie on my part because I have extra components on hand). I am hoping the chips arrive from the factory in a timely manner; I am quoted eight to 10 weeks' delivery time. I also have a quantity of new 30 MHz TTL clock oscillators for use as test generators. If you want the TTL 30 MHz oscillator add $2. I know you will want one as we will build test equipment with it next month.

Board test

As with any construction project, check it out with an ohmmeter. Check out the voltage regulator circuit with a resistance load, not with the Gunn diode. Make sure everything works as expected before you try the circuit and the Gunn detector diode as a complete package. As you test the variable voltage regulator circuit, check out the 30 MHz preamp. Inject a signal with a signal generator and see if the circuit is functioning at some specific frequency. Frequency prior to adjustment could be anywhere from 20 MHz to 70 MHz, depending on the components and values used.

I connect a signal generator and tune for the frequency of operation. When you find out where the circuit is receiving, you can trim the coil slug or add capacitance to bring the circuit to resonance near 30 MHz. The signal generator method works for a first cut as it tells you what the sensitivity and approximate frequency of operation are. When completed, both units should be set to exactly 30 MHz; or, if in doubt, set them to the same frequency (you can use the TTL 30 MHz oscillator for alignment). If other units are to be used they also should be set to the same standard: either exactly 30 MHz or all the same frequency.

Now, the other alternative to building the PC board 30 MHz IF amplifier: Use an inexpensive 88 to 108 MHz FM portable radio along with the modulator voltage regulator circuit. It's the same thing, except there's one provision: The stations you wish to

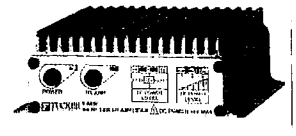
NEW PRODUCTS

V-100W

Two 2m Amps from Tucker

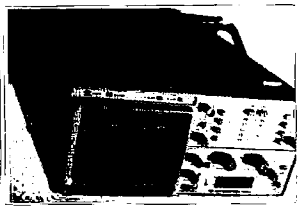
The new V-35W 2m VHF amplifier from Tucker Electronics features a built-in 15 dB preamp and a unique DC Monitor Meter that provides the operator with a constant reading of DC input voltage. The V-35W will accept 0.5-8W input power and produces up to 35W of output power. It operates on both FM and SSB/CW and is equipped with a built-in RF power meter.



V-35W

Tucker has also introduced the V-100W, which will accept 0.5-8W input power and produces up to 100W of output power. An input power signal of only 0.5W is required to produce 50W of output power, and 3-8W will drive the V-100W to full power output of 100W. Like the V-35W, it features a built-in 15 dB preamp and a built-in RF power meter.

Both amplifiers are designed to be used with 2m HTs and low-wattage 2m desktop transceivers, and both are covered by Tucker Electronics' one-year warranty and 30-day "Satisfaction Plus" no-questions-asked return policy. For more information, contact Tucker Electronics at 1717 Reserve Stree, Garland TX 75042; phone (800) 559-7388 or FAX (214) 340-5460.



Stop drifting!

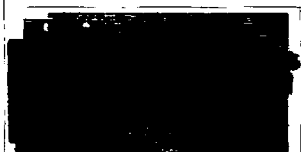
B+K Precision has just introduced four new spectrum analyzer models that are guaranteed to drift less than 0.150 MHz per hour, and this guarantee is good for a full year after purchase. All four models have stability and dynamic range equal to that of spectrum analyzers costing thousands of dollars more.

Two optional accessories are available: a battery pack to make the analyzers truly portable, and a 75Ω to 50Ω impedance matching adapter, to extend the analyzer's usefulness to 75Ω applications.

Models 2615 and 2620 are ideal for applications of up to 500 MHz. They include scanwidth selectors and an LED readout. Model 2620 also includes a tracking generator, a frequency synchronous signal source. Models 2625 and 2630 have AM and FM audio modulation to allow the user to listen to and identify RF signals. Model 2630 also includes a tracking generator.

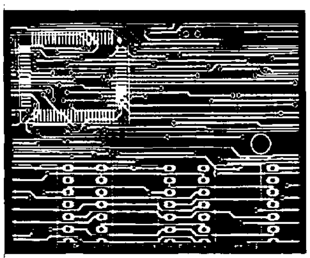
For more information or the name of the nearest B+K distributor, call 1-800-462-9832 or write B+K Precision, 6470 W. Cortland St., Chicago IL 60188.

Manufacturers: if you would like to have your products reviewed here, please call Fran at 603 924 0058.



ID to Interface Kit

Compared to high-priced modems and units costing five to 10 times as much, ITU Technologies' new Caller ID to PC Interface Kit is a price and performance breakthrough. It measures only 2.25 by 3 inches and can be plugged directly into any spare PC serial port. Software is included with the kit, for DOS and Windows-based programs. The ITU Caller ID to PC Interface Kit is a bargain at $39, plus $5 shipping and handling, from ITU Technologies, 3477 Westport Ct., Cincinnati OH 45248-3026. Call (513) 574-7523 or FAX (513) 574-4245.

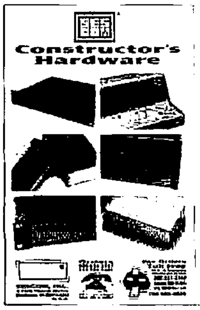


Produce perfect double-sided layouts in record time!

Number One Systems, in Cambridgeshire, England, is justly proud of the new, fast, powerful MultiRouter. Designing an autorouter to handle today's complex and dense layouts is no easy task, but the latest autorouting technology gets your routes through where other routers fail.

MultiRouter is a 32-bit multipass, shape-based autorouter. It uses proven push-and-shove and rip-up-and-retry techniques to achieve 100% completion on most layouts, and MultiRouter is so fast and easy to use, you could be looking at your first fully routed layout within an hour of installing the software. Surface-mount components? Memory Planes? No problem for MultiRouter!

MultiRouter works with Number One Systems' well-known PCB layout tool Easy-PC Professional XM. Together they form one of the fastest and most effective PCB design systems available for the PC and, priced at only £295 and £245 respectively, they are accessible to all PCB designers. US prices (including airmail) are $575 for MultiRouter; $475 for Easy-PC Professional XM. For further information contact Roger Wareham, Number One Systems, Harding Way, ST IVES, Huntingdon, Cambridgeshire PE17 4WR, Great Britain. Telephone +44 1480 461778; FAX +44 1480 494042. E-mail: rmw@numberone.com.



1996 Sescom catalog

If you're into building, you can't do without this catalog. If you're not into building, you're missing a heck of a lot of fun. Building stuff is like going on a DXpedition; you never forget anything you've built—never. Old Uncle Wayne still remembers the very first radio he ever built, back 60 years ago. Not having a Sescom enclosure, he built it into a cigar box. And it worked! Now send for the catalog from Sescom, 2100 Ward Drive, Henderson NV 89015-4249; (800) 634-3457, FAX (800) 551-2749. Then let's see what you can build with the Sescom tools and enclosures.

Where Am I?

Here's how to find your grid square.

Arthur C. White
Route 2 Box 5600
Talihina OK 74571

Do you know the grid square of your location? If not, do you know how to find it? It's something that should be on your QSL card because, more and more, it is of interest to a lot of your fellow hams. This article offers a step–by–step procedure for finding your grid square.

The present system of grid squares was adopted at a conference held in Maidenhead, England (and is commonly called the Maidenhead system). By the mid-1980s it had become a worldwide standard. In this system, the entire world has been divided into (1) fields, (2) squares, and (3) subsquares. A particular location may be known as EM 24 KR—field, square, and subsquare, respectively. We'll get to each of them in turn.

Fields

These cover the entire world. Each field is 20° wide in longitude (or east-west) and 10° in latitude (north-south). Starting at 180° longitude (the international date line) and proceeding eastward, each 20° field is designated alphabetically all around the globe until arriving back at the date line again (**Fig. 1**).

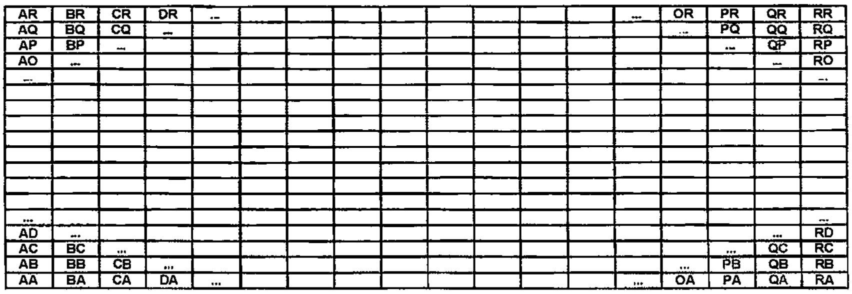

Fig. 2. North-south and east-west field designators are combined to create a two-letter designator for each 10° x 20° block on the face of the earth.

Since there are 360° in a circle, and since each field is 20° wide, there are 18 (360 ÷ 20 = 18) fields horizontally. Fields are designated with the 18 letters from A to R.

> ***"Given a longitude and a latitude, you can find your grid square location yourself."***

Similarly, starting at the South Pole and proceeding to the North Pole (a span of 180°), with each field occupying 10°, there are also 18 fields vertically (180 ÷ 10 = 18). These are also designated A to R (see **Fig. 1**).

So there are 324 (18 x 18) fields worldwide. All field designations start at the left and proceed to the right and then up. The longitude letter comes first, followed by the latitude, so that each field is specifically identified with a unique two-letter label. Your longitude and latitude at any place on earth determine the field you're in (see **Fig. 2**).

Of course, since the earth is round and the longitude lines converge at the poles, none of the fields is really square. They are wider on the side nearest the equator and narrower on the side nearer the pole.

Squares

Each field is divided into squares. A square is 2° in longitude and 1° in latitude. Hence, each field contains 10 squares (20 ÷ 2) in longitude and 10 (10 ÷ 1) in latitude, making 100 squares in all. Starting at the lower left corner, they are numbered from 0 to 9 towards the right, and 0 to 9 from south to north, again with longitude first (see **Fig. 3**).

Subsquares

Subsquares provide icing on the cake. To provide a higher degree of resolution, each square is divided into subsquares. Each longitude and latitude dimension is divided by 24, making 576 (24 x 24) subsquares. Since each square is 2° wide, 24 subsquares must each be 5' in

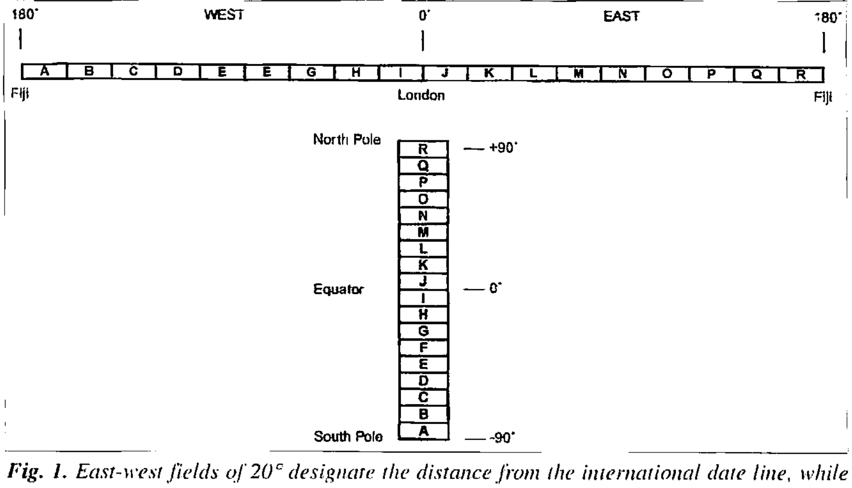

Fig. 1. East-west fields of 20° designate the distance from the international date line, while 10° north-south fields designate the location relative to the equator.

Fig. 3. Each field is divided into 100 squares, numbered from 00 in the southwest corner to 99 in the northeast corner.

longitude. Likewise, the 1° north-south distance of a square divided by 24 equals 2.5' in latitude. The subsquares are designated by letter, again starting at the lower left and proceeding to the right, and then from south to north, with longitude first. Hence, a location such as EM 24 KR designates a location on the surface of the earth within a 5' by 2.5' boundary. **Fig. 4** shows the western section of a square and the subsquare lettering system.

How to determine your location from scratch

The first thing is to know your longitude and latitude. Your library or a local surveyor may be a convenient source for this information. Say you're at 95°, 08', 55" west longitude and 34°, 43', 05" north latitude. We can simplify this to 95°, 08.9' west and 34°, 43.1' north (convert minutes and seconds to decimal minutes by dividing the seconds by 60 and rounding to the nearest tenth).

Let's begin by considering our longitude designators. We'll work eastward from the date line. First, determine how many fields you are removed from the date line. In this case, we are 180° – 95°, 08.9', or 84° 51.1' away (see **Fig. 5,** top).

AX	BV	...		
AU	...			
...				
...				
AD	...			
AC	BC	...		
AB	BB	CB	...	
AA	BA	CA	DA	...

Fig. 4. Each square is divided into 576 subsquares, designated AA in the lower left to XX in the upper right.

Note that if we were located in the Eastern Hemisphere, we would simply add 180° to our longitude to find our longitude distance from the date line. We have now established the first letter of our location: E. Since each field is 20° wide, 84° 51.1' puts us just past the fourth field (80°) and into the fifth.

Now, how far inside E are we? 84° 51.1' – 80° = 4° 51.1' so we are 4° 51.1' past the fourth field. Squares are 20° wide, so 4° 51.1' ÷ 2° = 2 with 51.1' remaining, so we are in the third square, which gives us the first digit in our square designator: 2 (see **Fig. 5,** middle).

Now we are 51.1' within square 2. Since the square is divided into 24 sections of 5' each, then 51.1' ÷ 5' = 10 + 1.1, so we are in the 11th sector. Our designator for the 11th subsquare, therefore, is K (**Fig. 5**, bottom).

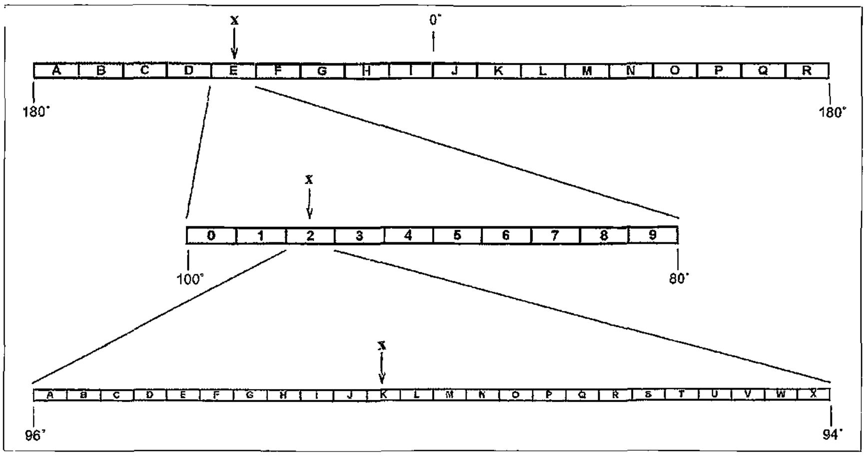

Fig. 5. The longitude portion of the grid square designator is found by locating the proper fields, square, and subsquare (top to bottom).

Now for the latitude indicators. Our latitude is 34°, 43.1' north. Starting from the South Pole, with a letter assigned to each 10°, we find we are in field M (**Fig. 6**, left). We are 4°, 43.1' north of 30° which places us in square 4 (**Fig. 6**, middle). And we are 43.1' north of 34° with 43.1' ÷ 2.5' being 17.24, so we are in the 18th subsquare above 34° which is R (see **Fig 6**, right). Combining our three latitude indicators with the previous longitude indicators (keeping the longitude first in each case) gives us the complete grid locator: EM 24 KR.

That's all there is to it. Given a longitude and latitude, you can "do it yourself." Try it.

Reference: The *ARRL World Grid Locator Atlas.*

Number 76 on your Feedback card

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad. This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the August 1996 classified ad section is June 12, 1996.

NEVER SAY DIE

Continued from page 68

"If winds of tornado strength poured into the void left by the precipitating atmosphere, Coriolis forces would cause them to spiral about the pole in a counterclockwise direction—the same as the Earth's rotation—carrying considerable oceanic waters along the way. Further, the cumulative energy of the massed atmosphere would cause it to pile up at the pole and subsequently helically spiral upward into space.

"Does HAARP have the potential to generate such an electrical discharge? We don't know. But, if the means were at hand to make the sun go nova, there would be those who would be eager to make the attempt. This would automatically terminate the experiment, but this would be beside the point."

Maybe you can understand why the Alaskan legislature is beginning to get worried about the rapidly being built HAARP project in their back yard. I'm not worried. Amateur radio has provided me with a wonderful lifetime of adventure, so if some government-funded scientists blow the world to smithereens instead of investing the money in developing cold fusion as a low-cost source of pollution-free energy, big deal.

But maybe, if you tend to be a worry-wart, you'll want to read Begich's book and get a better handle on what's going on up there in Alaska. Or maybe you are comfortable, confident that the government knows what it is doing.

I Beg To Differ

Maybe you've noticed that we come in all sizes, shapes, colors, and temperaments. It's a problem for the clothing industry, which they haven't managed to cope with all that well. It's been less of a problem for our school system, which does its best to force all children, no matter their IQ or other characteristics, into a one-size-fits-all educational system. The fast get slowed. The slow get run over.

Our medical industry uses the same one-size-fits-all approach. For instance, there's one RDA, the recommended daily average dose of vitamins and minerals for people, no matter their size or shape, or any genetic differences in their body chemistry. Ditto immunization shots, and so on. Sumo wrestler or 97-pound weakling, everyone gets the same shots.

The fact that our genetic makeups are all different is one we can plainly see, with variations in skin color, height, body build, and so on. Does it make sense that we might just all be somewhat different chemically too? We know that we're all allergic to different things, right? Thus, maybe it stands to reason that our bodies are going to have somewhat different needs when it comes to vitamins and minerals and resistance to poisons. So should it be surprising when some people have violent reactions to some medications and shots? Some even die, but the number is acceptable to the medical profession. And the government.

Some people are more easily addicted to nicotine, alcohol, caffeine, and other drugs than others. And a few of our soldiers got sick (some died) from the barrage of immunization shots they got on their way to the Gulf War. Acceptable losses, no doubt. And the fluoride put in our drinking water kills a few people. Tough. Our water supplies are 60% fluoridated. Those in Europe are under 2%. Obviously they're a backward people. I'm sure it's a coincidence that fluoride is used on animals to make them more docile and we're seeing similar side effects with our people in cities with fluoridated water.

But books have already been written on these subjects, complete with references to research reports. So read the books first and then argue with the authors. I don't want to turn my editorial into an in-depth report on things that books cover much more thoroughly. I just want to wave the red flag and point you toward learning more and not docilely accepting what our caring government, and the big money industries which guide and drive it, do to you.

Crankcase Sanding

Mother Nature (aka God) spent several million years developing our mind/bodies into an incredibly intricate system. It has evolved perfectly adapted to the environment, designed to perform optimally on the food, water, air, and sunlight that was available during this development period. Does that make sense?

The more I read and listen to people who've spent years studying health and longevity, the more convinced I am that if we were to provide our bodies with the same food and water it was designed to handle, it would last at least double the mileage we're getting out of it now. We're putting sand in our crankcase, sugar in our gas tank, sludge in the radiator, and throwing garbage in the back seat of the fantastic limo we were issued at birth.

Let me put this another way. How much would you be willing to pay right now to get one more week of life 20 years from now? A buck? A hundred? A thousand? Okay, what would you pay to put off dying today until a week from today? Every nickel you have or could borrow, right? You might want to sit back and think about that. Put it into perspective. How important is next week for you? Next year? Ten years from now?

Does the prospect of being able to live healthily until you are 150 seem at all attractive? Yes, there are men over a hundred who are still fathering children and who are probably a whole lot healthier than you are right now.

Is this important enough for you to make an effort to learn more about your health and what you're doing every day to ruin the fine machine you were issued at birth?

Tomorrow

Tomorrow I'll start eating healthier food. Tomorrow I'll start taking those walks. Tomorrow I'll get some sun. Tomorrow I'll read that book Wayne recommended. Next week I'll start that small business I've been thinking about. Next week I'll get started toward upgrading my

Number 77 on your Feedback card

UPDATES

Which switch is which?

In the May issue, '96, we mislabeled a switch in each of J. Frank Brumbaugh's schematics. First, in "Simple Multi-use Amplified Speaker," on page 41, the switch that's connected to BT1 should be labeled S1. Then, in "Antenna Noise Bridge Detector," on page 78, the switch that is labeled S1 and connected to BT1 in the upper right of the schematic should be S2.

It's alive!

In May's *73*, "How to Make an Old HW-8 Come Alive" appeared on page 42; author Gerald Gronson K8MKB has alerted us to a few changes that should have been made.

Resistors Rb and Rc: 33,000Ω. Ra: 1Meg. R27 is between 3.3 Meg and 2.2 Meg. Try 3.3 Meg; if, with the volume control wide open, the receiver breaks into oscillation, replace it with the next-lower 5% value (a larger R27 resistor makes for higher gain in the IC2C stage, however). R205 can be 1.5k (whatever is on hand).

In Fig. 2, the capacitor labeled "C" can be anywhere from 1μF to 5μF tantalum or electrolytic, 15V unit (μF value not critical). C38's only change is to 4.7μF (or 5μF—it doesn't matter; whatever capacitors are on hand—all 4.7μF or 5μF are OK). C31 should read .1μF to .05μF.

ticket. Next month I'll buy that new rig. Next year I'll go on that DXpedition.

Blue collar jobs are moving to lower wage, higher automated countries. White collar jobs are being replaced by computers and better communications systems. Upper management jobs are being downsized. Pensions are an endangered species, except for government workers.

A generation or so ago you used to be able to pretty much count on retiring at 65 with a gold watch and a nice pension. Then the big corporations figured out that it was a whole lot cheaper to get rid of upper management people by bumping them out before the generous pensions kicked in. That cut down on their long-term liabilities, making their stock more desirable.

Now, many of us are forced to face that tomorrow when, in our 50s, suddenly we may be laid off. Fired. Canned. Talk about a mid-life crisis! You're too old to be of any real interest to another large company. You never put much aside, preferring to enjoy a nice home, an expensive car, and lots of toys to planning about tomorrow, so even if you had a small business in mind to start, you haven't the savings cushion to do it. So what do you do?

Our Blind Media

Thanks Mike Browsher K8HQQ for a clipping from *Media Bypass Magazine* on the decision "not to run" by 45 members of Congress. Other than an "oh my" or two, I haven't seen much in the media about this wholesale evacuation of DC.

The article asks why all these politicians are willingly giving up their seats of power and endless money. Their answer is that a small group of computer hackers (called the Fifth Column), formerly with US intelligence agencies, have been tracing the secret foreign bank accounts of our politicians and in many cases repatriating billions of their dollars to the Treasury. Each of the "not running" or "retiring" officials has, according to the article, been handed a detailed report of their Swiss bank transactions. The options: retire immediately or face widespread distribution of the information, including the IRS.

There are a thousand ways for officials to sidetrack re-election funds, honorarium, bribes, lobbyist donations, and so on. Politics can be a ver-r-ry lucrative career path. A threat to investigate the liquor industry brings in massive bribes to stop that nonsense. Ditto every other controlled industry. And most of our larger industries are controlled by a small group of men. I remember when Senator Dodd of Connecticut got caught pulling this extortion.

When I got involved with the music industry I found it totally controlled, from performers to record stores, by seven mega-corporations, six foreign-owned. They controlled record store distribution, radio airplay, juke boxes, and so on. Fewer than 5% of their performers ever made a nickel in royalties due to bookkeeping practices similar to those in the movie industry. And so it went.

The magazine distribution industry is even worse. Ditto the medical industry, the education industry, and so on.

If you think I am exaggerating and have any facts to support it, please let me know. I've done my homework on this pretty carefully. More likely, you'll tell me about the corruption in the industry you're involved with.

Doctors

Like you, I was brought up to look on doctors as experts I should turn to when I get sick. It's been difficult for me to get over that early programming. And probably, despite my editorial educational efforts, I've failed to shake your belief in their expertise. The sad fact is that doctors are in a fix. It costs a fortune and years to get the license to kill, and they have to go through the warping experience of medical school, where the curriculum is controlled by earlier experts. And this whole works is solidly in the hands of the pharmaceutical industry, supported by the FDA, NIH, and WHO. And they're kept in control via Congress and millions of dollars from lobbyists.

So we have spectacles like the continuing resistance to the low-cost cure for ulcers. And all this AIDS nonsense, which is a billion-dollar industry. Duesbery has a new book, *Inventing the AIDS Virus*, which I haven't read yet. I did read his earlier book on the subject, and this one further confirms his claims that the HIV virus is not the cause of AIDS. I've recommended the similar book by Dr. William Douglass of *Second Opinion*, which claims that AIDS was developed and spread on purpose by the World Health Organization.

AIDS is a billion-dollar industry, so the worst fear of those in the business is a cheap, simple cure. This is why the Beck approach has been resisted so strongly by the AMA, FDA, and AIDS researchers and workers, despite the credentials of the Albert Einstein College of Medicine and 15 patents for the process being issued to hospitals.

Have you read *Racketeering In Medicine* by Dr. Carter, which is on my list of books you're crazy if you don't read (my list is $5 from Radio Bookshop)? I've added *Dirty Medicine* by Martin Walker, a 733-page thoroughly documented indictment of the medical industry, to my list on the latest update. Slingshot Publications (London), ISBN 0-9519646-0-7 ($24).

The sorry fact is that if you have any interest in living long enough to get your Social Security taxes back, and living it in good health, you've got to do your homework, because the doctors you've been trusting haven't. They're generally busy dealing out prescriptions for drugs and operating to repair the mischief they and you've done to your body through negligence. Like lousy food, polluted water and air, a lack of needed minerals, immunization shots, and so on.

Yeah, I suppose I may come across as a health nut. Well, there are a lot of 'em out there who've been caught up in vegetarianism, macrobiotic diets, fasting, popping handfuls of vitamins, and so on. I like to see ideas supported by common sense and by a number of different researchers so I don't buy into some kind of nincompoopery. And, since I'm almost to the age when half of my compatriots are already dead, it's probably about time that I started paying more attention to the maintenance of my body.

Of course, if you don't mind annoyances like cataracts, Alzheimer's, allergies, arthritis, diabetes, herpes, osteoporosis, heart attacks, high blood pressure, and so on, hey, it's your body, and from what I've been reading in books recommended by your fellow readers, none of this is necessary or unavoidable. It's not God or chance that's rolling the dice, it's you.

Mamiya RB-67 Wanted!

The best equipment photo camera I ever had was the old Mamiya RB-67. Then my staff photographer swiped it when she quit. Ouch! But how do I prove it? I've been making do with my 35 mm Nikon, but I'd like to replace my old RB-67, which has a 6 cm x 7 cm negative, and therefore makes the sharper pictures needed for magazine use. The problem is that I'm thrifty (NSD = never spend a dollar), so I'd like to hear from any reader in the camera business who might be able to find an old used RB-67 for me at the wholesale price. Camera, back, and a 127mm or so lens. Maybe a macro lens?

Really Bugged

I've been living in NH for 34 years now and I've never seen anything like the ladybug infestation we had this spring. I was amazed last fall when I was out in the yard pulling dandelions one day and I was almost covered by ladybugs. Then, all through March and April, the windows on the west side of the house were crawling with them in the afternoons.

Everyone knows that ladybugs are good, so I was surprised to find that they bite. Ouch! Hmm, so I started collecting them as they managed to somehow crawl inside my windows and take them downstairs to our dining room mini-rain forest. Well, big deal, eh? Hey, I'm talking 100-500 bugs some days! Inside. Never in all the years I've lived here can I recall seeing even one ladybug coming inside like that.

I visited a chap who lives about 20 miles from here and one of his windows was swarming with ladybugs too. What's going on?

The X Files

While I enjoy the Fox™ program of the same name, in this case it has to do with transmutation. X, as in x-former or x-mit. Well, we use "x" for xtal...meaning crys, perhaps short for cross. With the cold fusion research going more and more into the transmutation of elements as an explanation for the excess heat being developed, I've been keeping my eyes open for anything relevant. I've written about

this recently, so I won't go over it again.

Anyway, when I read about a transmutation experience in René's *The Last Skeptic of Science* book, I quickly rattled René's cage for more details. The experiment described in the book was his and Pete Ross's effort to whip up some small diamonds out of carbon.

Back in 1977 they made a furnace out of a 25-gallon steel drum, which was split in half lengthwise and laid on its side. They lined it with lime as a refractory material. They set up two long 3" diameter carbon rods for the arc and powered them with a large electric arc welding machine. They loaded the arc area with calcium carbide and turned on the power.

Once the arc got going, the rods were pulled back and the arc was able to continue, but it was only drawing 260 watts, while the heat being generated was more in the thousands of watts range. The following day, the pot started growing into a baby volcano, percolating up hot viscous material, much like a volcano's lava. Concerned, Pete lowered the power to slow the growth. It didn't slow, so he poked the bubbling mound with a half-inch steel rod. It instantly vaporized at least a half inch of the rod, shooting a blue-white light beam toward the roof of the old warehouse where they were working. Pete quickly shut off all power, yet the volcano continued to grow.

To stop the runaway volcano Pete broke open its walls and poured in more calcium carbide. This stopped the reaction.

The bad news was that when they sorted through the remains, the few tiny diamonds they found were of a poor quality and worth less than the current consumed making them. The good news (for scientists willing to pay attention) was the anomaly of finding higher atomic weight elements. Nothing with an atomic weight over 20 went into the mix, and elements up to 83 (bismuth, which is heavier than lead, and is as high as you can go without getting into the radioactive elements) resulted. They found a lot of iron ($_{26}Fe$), which could be calcium ($_{20}Ca$) plus carbon ($_{6}C$).

They tried for several years to get universities to redo the experiment and confirm the transmutation products. But since the transmutation of elements is "impossible," they could find none that would even try. I asked René what happened to Pete and he said that Pete had gotten interested in computers, had hacked his way into the CIA computers, and shortly after suddenly disappeared one day and nobody, including his family, has ever seen or heard from him since.

If you decide to try this, be sure to have plenty of room around for accidents. René says to have the electrodes spring-loaded so they can be pulled apart quickly when things start to take off by themselves. And remember that virtually all of the major breakthroughs in science have been made by amateurs who didn't know that it couldn't be done. Remember, too, that few of the beliefs in physics 50 years ago are still believed today. I'll bet the same will be said 50 years from now.

René's *Last Skeptic* book is available exclusively from Radio Bookshop. It's $25 + $5 s/h. It will keep you armed with interesting things to talk about for weeks.

A Little Late

Vern Hargreaves K4HMV just sent me a QSL, for which my thanks. It was for a 1948 2m contact. I hope Vern isn't as far behind with everyone else. Vern is not only still active, he's also a subscriber and contributor to my *Cold Fusion* magazine, plus an early experimenter with the Beck blood purifier circuit.

That reminded me that the 50th anniversary of our return to the air after WWII went by without any special notice. Since I was teaching radio at the New London (CT) Submarine Base at the time, I was able to get on the air the day they opened 2-1/2 meters with a radio in my lab. That weekend I brought my pre-war walkie-talkie up from Brooklyn. It had a 1G4GT oscillator with a 1Q5GT modulator and superregen receiver. I made contacts from a hill on the sub base evenings. Then they opened 10m, and I got on there the first day the band opened. One of my first contacts on 10m was Ed Ricca W2OCL (now K4PT).

Thanks Vern, for the QSL.

McDonald's

A reader sent me a McDonald's place mat extolling the importance of immunization and giving the ages at which children should be given shots, citing the National Medical Association and the National Council of La Raza, whatever they are. Are they fronts funded by the pharmaceutical companies? I sure hope you do your homework on this one and at least read *Immunization, The Reality Behind the Myth*, by Walene James. It's on my $5 list of "Books You're Crazy if You Don't Read." If this book doesn't turn you into a religious fanatic opposed to immunization, let me know.

We spend 30-40% more on "health care" than any other country in the world, yet we have 40 million people with arthritis (a nutritional disease), 15 million with asthma, and over a million new cancer cases annually, of which half will be fatal. And the situation is getting worse, not better! Heck, according to a Nader report, over 300,000 people die a year just due to mistakes in hospitals.

Until mass immunization of our kids came along, autism was virtually unknown, as were dyslexia, learning disabilities, and hyperactivity. Now we have millions of hyperactive kids, so we drug them with tranquilizers, frying their brains, and wonder why the SAT scores have been plummeting. No problem, they just lowered the scale.

What can *you* do about it? Well, if one 13-year-old kid can make a worldwide fuss over child labor, complete with an interview on *60 Minutes*, you too can move mountains. Arm yourself with the facts and then get busy. One way to have a good chance at being able to change things is to run for your state legislature. That will give you access to the media, and an opportunity to make a difference.

Or have your brains been fried too?

ABOVE & BEYOND

Continued from page 71

communicate with must also use the same frequency range (IF) to receive on. It doesn't matter what frequency you select—just tune the FM radio to a quiet place on the dial, say the lowest frequency, 88 MHz. The modulator must still be used as is. Of course, the frequencies on 10 GHz will now be 88 MHz apart instead of 30 MHz, as with the PC board unit. Now this is a simple project; I hope you enjoy simple microwave operation.

Well, that's it for this month. Next month I will cover some additional test circuits to add pleasure, smooth methods, and test procedures for microwave operation. One of them is the microwave reflection antenna using the 30 MHz TTL oscillator. For questions, drop me a line on the Internet at clhough@aol.com, or send an SASE to the address at the beginning of this column.

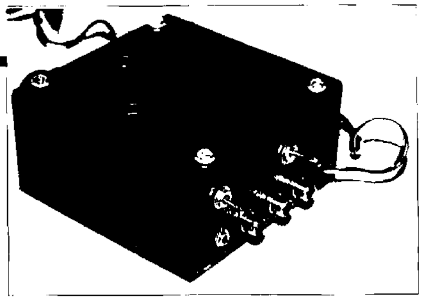
CMOS Super Keyer 3

"State-of-the-Art Keyer Kit is a Bargain!"



Marshall G. Emm AAØXI/VK5FN
2460 S. Moline Way
Aurora CO 80014

It's probably a sign of the times, but when it comes to Morse keyers and keyer kits, there isn't a whole lot to choose from. There are lots of "basic" iambic keyers based on the Curtis 8044ABM chip or an imitator, starting at around the $20 mark. Then there are the all-the-bells-and-whistles memory keyers, which start at around $100 and go well above that figure. So it was a pleasant surprise to find a memory keyer available as a board kit for a mere $58 postpaid.

The CMOS Super Keyer 3, available as a board kit from Idiom Press, is a full-featured keyer, with a substantial amount of memory (1530 characters) configured as either 6 or 18 separate messages, and enough functions and features to fill a couple of books; for example, the tutorial and operating guide that comes with the kit. It does just about everything you can think of, and the price is substantially below that of any other memory keyer or kit presently available.

The features of this keyer are too numerous to describe individually. There are twenty listed features on the first page of the manual, which include burst sending to 990 wpm, contest serial numbering, and full beacon capability. There are 19 function commands, 18 inquiry functions, 11 programming functions which can be embedded in stored message text, and 7 two-button direct commands.

Some features that I found to be of particular interest:

You use Morse to communicate with the keyer. Commands are sent from the paddle, and the keyer responds, in Morse, via the speaker!

All settings and the contents of the memories are stored in NV RAM, which is permanent and does not require a battery or power connection.

Power consumption is extremely low, typically 20 mA key-down and 10 µA when idle, so it is perfect for battery operation in emergency conditions.

"It's probably fair to say that the CMOS Super Keyer 3 is the most feature-rich and flexible keyer on the market."

You can select any of ten different keyer emulations so the CMOS 3 will work just like the keyer you are used to.

It's probably fair to say that the CMOS Super Keyer 3 is the most feature-rich and flexible keyer on the market, but there is a catch, or two....

First, when Idiom says "board kit" they mean exactly that. You get the circuit board, the board-mounted components, and the tutorial/operating book. That's it. Figure another $20 or so for hardware: a box, six push button switches, a pot for speed selection, speaker, and jacks for paddle and key line. I added a straight key jack, and a second keyed line with a switch so that I can key rig a, rig b, or both. I also added an LED, a type 7805 voltage regulator (RS276-1770), and a manual tune switch.

Second, although the CMOS 3's antecedents have been around a long time (the CMOS II was described as a project in the ARRL Handbook from 1992-1995), it's not like buying an ordinary kit, exactly. Version 3 was announced and described in the August issue of *QST,* and shown on the magazine's cover as a "weekend project," but you couldn't build it from the article; there is only one supplier of the board and the programmed chip. So in this reviewer's opinion, the article should have been labeled as a product announcement and not a project, but that is, of course, a criticism of *QST,* not the keyer.

The "kit" from Idiom does not include any construction information or instructions. There is an oblique reference to a "construction article" which turns out to be the article in the ARRL Handbook (in accordance with Murphy, I have the '91 and '96 Handbooks). In subsequent correspondence, Idiom has promised to include at least minimal construction information.

Construction

Building the CMOS 3 is relatively straightforward— it's a matter of populating the circuit board and making the connections. Without any instructions, you will need to consult the circuit diagram (in the center of the manual) to identify component values. There are only two issues which may require clarification. You can probably deduce both of them, but I have found that it is generally not advisable to make any assumptions when building a complex kit!

1. The orientation of the resonator Y1 doesn't matter; it can go in either way.

2. Some external wiring uses a shared ground return connection (e.g. the switches), while other components have labeled connections for both wires.

You will need to be very careful with the soldering. The CPU chip socket has 38 pins, and the tracks on one side of it are the closest I have ever seen. You will need a very light soldering iron with a fine tip. I soldered under a large magnifying glass, pausing frequently to check my work with a 10x loupe.

Since both ICs (the CPU and memory) are CMOS devices, they are extremely sensitive to static electricity. Handle them no more than absolutely necessary, and it is a good idea to ground yourself whenever you are working with them. A ground wire with an alligator clip attached to your metal watch band or a finger ring is fine. Before you insert the chips in their sockets, connect the negative power supply lead first and ground it.

RFI Problem

The CMOS 3's CPU is a computer, and, like all such devices, it generates RF hash which is audible across the HF spectrum. Without shielding, the level is high enough to cause problems with reception, and makes QSK (break-in) operation impossible. Note that the hash is generated only when the processor is working, i.e. when you key it, send a command or inquiry, or send from memory. If you use the beacon mode to send CQ, the hash will be generated during the pause between calls, so you should do everything possible to minimize it.

You can add bypass capacitors to all external connections, and, as suggested in the *QST* article, you will want to install the keyer in a metal box. Indeed, one of the authors made the illustrated box from copper-clad PC board material. Finally, use shielded (e.g. audio) cable to connect your paddle and your rig.

I did all of the above (using a steel box in place of a copper one), and still have a problem. Next step will be to "deconstruct" the keyer and place ferrite beads on all wires connected to the circuit board. As it stands, the level of RFI is just a nuisance and not a critical problem.

Operation

The CMOS Super Keyer 3 is a joy to operate. There are a lot of functions and commands, but they are generally mnemonic and therefore easier to use than the digital codes common on "keypad" keyers. For example, you put the keyer into inquiry mode and send "S" to have it report the currently selected sending speed.

The keyer has three operating modes:

Direct Sending mode. Whatever you send with the paddle is processed and used to key the transmitter directly.

Command mode. Pressing one or more buttons causes the keyer to send from memory or carry out programmed or keyed instructions. For example, pressing button 1 causes the keyer to send the contents of memory register one. Simultaneously pressing buttons one and two puts the keyer into keyed-command mode, and you use your paddle to send the relevant function command.

Inquiry mode. Simultaneously pressing buttons five and six puts the keyer into inquiry mode. Paddle an inquiry command and the keyer will respond by "sending" the current setting.

In both command and inquiry modes you will receive feedback in Morse from the speaker, and you can set a different speed for this type of communication than the sending speed. Communication between the user and the keyer is handled "off-line," without keying the rig.

The designers, KCØQ and NØII, are amenable to suggestions; indeed the *QST* article says that Version 3 arose largely from user feedback. There are some things I'd like to see in a software upgrade, and in the context of a review it should be noted that these are things that are missing in Version 3:

A function to set an absolute speed in wpm. As currently programmed, you can achieve the same effect by specifying a range with the same figure entered for both upper and lower limits, but this is clumsy and requires a second command in order to make any speed change later (the speed pot is "disengaged").

"You can build the CMOS Super Keyer 3 in about three hours."

Have a paddle-touch terminate memory sending without keying the paddled element. Some keyers work one way, some the other, so perhaps this could be a user-selectable option.

Offer "bug mode" as one of the emulations, i.e. have the dit paddle send dits, but the dash paddle in "straight key" mode.

A function to copy the contents of one memory location into another. This would allow for easier building of complex messages with repetitive text.

An ability to edit a message from the first word, and/or an ability to insert text into an existing message.

Conclusion

If you have good soldering skills, you can build the CMOS Super Keyer 3 in about three hours, depending on how you handle the hardware options. The result will be a keyer that is every bit as good as any keyer you can buy, with the advantage of relatively low cost.

Availability

The CMOS Super Keyer 3 kit, comprising circuit board and all board-mounted components, is available by mail order only from Idiom Press, P.O. Box 1025, Geyserville CA 95441 (916) 857-3524.

Ham Shack Test Equipment

Continued from page 10

SWR analyzer

This commercial instrument is invaluable for measuring antennas, as well as at the end of the feeders in the shack. It also enables you to determine antenna tuner control settings without putting the transmitter on the air and generating QRM.

Several manufacturers offer different models, for HF as well as VHF and UHF. Many include an LCD readout of the frequency of the internal oscillator, and can be pressed into service as frequency counters over their ranges, although most require a fairly substantial input signal. Some also measure radiation resistance at the feed point.

Some, possibly all, can be used as a dip oscillator to check the resonant frequency of tuned circuits, and the value of either L or C if one or the other's value is known accurately. MFJ offers an adapter, primarily a coil of wire wound on a form, for several models of their analyzers, allowing them to be used as accurate dip oscillators.

Although the tuned oscillator in these analyzers is not especially stable, it can be used as a signal generator. The output of most analyzers is relatively high; the RF voltage approaches 1 volt RMS no load at 160 meters, and a bit less as the frequency is increased. You should use an attenuator if you're feeding the antenna input of a receiver directly, or stick a wire in the central output terminal and radiate a signal to the receiver.

In general, prices begin just under $100 and go up. Look at what is available, considering the bands you normally work or plan to work, and choose the best analyzer you can afford. An SWR analyzer is strongly recommended as an invaluable addition to your shack.

Field strength meter

A small field strength meter sitting at your operating position will continuously monitor the power radiated from your antenna, when it isn't being used to check the radiation pattern, front-to-back ratio, and major lobe width of your beam. The ham literature is filled with many different designs for various types of field strength meters, and home-brewing is the cheapest way to go.

A short vertical whip or piece of stiff wire feeding a voltage doubler, consisting of a pair of germanium diodes bypassed by a 0.01 µF disc capacitor, into a 10k ohm pot with a microammeter from wiper to ground will be adequate for most ham stations.

Should you require accuracy instead of relative measurements, the *ARRL Handbook* has had a suitable design for several years. Commercial (and extremely expensive) accurate instruments with digital readout are available from several manufacturers who advertise in ham magazines.

Frequency

Accurate frequency measurement is necessary when aligning receivers, checking band edges, calibrating analog dials on home-brew receivers, VFOs and some test equipment, and in many other situations.

The simplest and cheapest way is to build a secondary frequency standard (crystal marker generator). A unit based on a digital oscillator using a 74LS00 and a 10 MHz surplus microprocessor crystal, followed by a few 74LS90 decade dividers and a 74LS74 dual flip-flop, will produce known, stable frequencies of 1 MHz, 100 kHz, 50 kHz, 25 kHz and 10 kHz, with harmonics well into the VHF range. The 10 MHz oscillator must be set on frequency either with a frequency counter or by zero beating against WWV during the seven-second period every minute when the carrier is not tone modulated. The cost of the marker generator should not exceed $10, though it can be zero if you have a well-filled junk box or know someone who does.

A much handier (and highly recommended) step up is to purchase a commercial frequency counter. A great many are available, covering different frequency ranges and having differing sensitivities at various prices, some of which are rather high.

If you are interested in microwaves, you will want a counter capable of making measurements in the gigahertz range. If you usually operate HF, VHF, or UHF through the 70 cm band (this includes the majority of hams), my personal recommendation is the Ramsey CT-90 frequency counter. It covers 10 Hz to 600 MHz with a nine-digit LED readout and three gate periods: 0.1, 1, and 10 seconds. Sensitivity is less than 10 mV from 10 Hz to 150 MHz, and less than 150 mV up to 600 MHz. Constructed in the standard small Ramsey cabinet, about 5" x 5" x 1-1/2" high, it can be powered by 12 volts AC or DC, or by four AA NiCd internal batteries which are kept charged whenever the supplied wall transformer is in use. Ramsey offers two probes, one for 10 Hz to 20 kHz and the other from there to 600 MHz, but you can easily build your own for a very few dollars. The advertised price for the CT-90 is $169.95. (Ramsey Electronics Inc., 793 Canning Parkway, Victor NY 11454; (716) 924-4560).

Although I use the Ramsey and recommend it highly (I operate only 40 through 10 meters), there are a number of manufacturers offering frequency counters and you should investigate them all, depending upon your own special needs. Compare specifications and prices, and then choose the best instrument for the money.

Inductance

The chances are that unless you do a lot of experimenting and building VFOs, receivers, etc., you won't need to measure many small inductances. However, for home-brewers and QRP enthusiasts who do need to know the value of small coils (20 µH or less), there are several choices.

Commercial LCR meters, which look much like DMMs, are widely available from many manufacturers at fairly high prices. Buying one if you already have a full-function DMM is overkill. Other much more expensive inductance bridges are available commercially, but most hams can't afford them and don't need them. Occasionally a "boat anchor" such as the superb Boonton Q-Meter becomes available on the surplus market, but at a fairly high price.

Another choice is to build your own. The 1995 *ARRL Handbook* describes a multi-range inductance bridge. Several ranges are beyond those of interest to most home-brewers, but they might come in handy someday.

My personal recommendation is one that I designed and used (see "The Handy Inductance Bridge," *73 Amateur Radio Today*, May 1991, page 11). I have since modified the RF generator, eliminating the two transistors and substituting a 74LS00 crystal oscillator.

For a simpler, cheaper inductance meter, please see: "A Simple Inductance Meter," *73 Amateur Radio Today*, June 1996. This is not a bridge and uses an entirely different means of measuring inductance, eliminating the need for a zero-center meter which the instrument in the 1991 reference requires.

Capacitance

In case your DMM does not measure capacitance, you can construct a simple, accurate instrument for less than $5.00. Please see "A Simple Capacity Meter," *73 Amateur Radio Today*, March 1996, page 71.

Audio frequency generator

A stable, known frequency source of clean audio between 300 and 3,000 Hz is necessary when checking audio circuits, and is invaluable when designing and building active and passive audio filters, and when setting the center frequency of SCAF filters. The frequency must be variable, and so must its level; this eliminates small, fixed-frequency oscillators. Commercial audio generators covering several wide frequency ranges are available. Not only are they large and costly, but they also have much broader capabilities than the 300-3,000 Hz most hams need. A much cheaper and far more stable and accurate option is to build your own (see "Crystal-Controlled Audio Generator," *73 Amateur Radio Today*, November 1995, page 28. Note: There is an error in the schematic; C11 should connect between the Q3 emitter and the Q2 emitter.) This simple instrument covers the 300-3,000 Hz range when calibrated. The parts cost should not exceed $10. The stability and accuracy will be that of the crystals used.

Multiple voltage module

It is true that "you can't have too many power supplies." However, power supplies are bulky, costly, hot and, unless needed most of the time, represent a waste of dollars. However, it is often necessary to provide a fixed voltage to a circuit being designed or a piece of equipment being tested or serviced. Most of the time the needed voltage will be other than that supplied by the station power supply. A common example is the +5 volts required by TTL digital circuits, or the 6 or 9 volts needed to power a portable radio you're working on.

The home-brew answer is cheap and simple. Mount 7805, 7806, 7808 and 7809 regulators in a small aluminum box (which also serves as a heat sink for the regulators). Mount at least two RCA jacks for each voltage output. Feed the box with 13.8 VDC from your station supply. Bypass the DC line where it enters the box with both a 0.001 µF and a 0.1 µF capacitor. Use the same values of capacitance to bypass each pair of voltage output jacks.

To make this unit even more versatile, connect a 317T variable regulator and a 5k pot and another RCA output jack (remember to bypass it) and you'll also have an ampere at about 2 to 12 volts DC. Don't forget to insulate the tab of the 317T from the case.

Oscilloscope

Of all the items of test equipment helpful to hams, the 'scope is the most useful and versatile. However, they are large, generally heavy, and always expensive; not every ham can afford one. But, if your budget will stretch that far, a good wideband oscilloscope will be most useful.

For the ham who operates primarily in the HF bands, a 'scope with a 50 MHz bandwidth will do a fine job, although a 100 MHz bandwidth would be even better. It should be a dual-trace 'scope. Occasionally such a 'scope appears on the surplus market, at a price starting around $350. Such 'scopes were built by companies like Hewlett-Packard, Tektronix, etc., for the military. All of these are solid state (except for the CRT) and dual-trace. Most have a 100 MHz frame, but many will have 50 MHz. Those built for the Navy cost the taxpayers $3,300 each, and they are "built like a battleship" and almost as heavy. If you can afford $350-$400 or so and can find one, grab it!

Some rather large and heavy vacuum tube-type Tektronix 'scopes in their 500 series are usually available from outlets such as Fair Radio Sales, Inc. in Lima, Ohio, but I do not recommend buying even a bargain 'scope which is from the vacuum tube era. Tubes have become scarce and expensive. This supplier, as well as Tucker, often have other suitable surplus 'scopes. Get their catalogs and keep checking ads. To my knowledge, for you microwave buffs, oscilloscopes with a bandwidth of 3,000 MHz are available but their cost is prohibitive.

About the only other option is to locate a good, recent Heathkit® 'scope with a 5 or 10 MHz or more bandwidth at a hamfest, and if it works and the price is right, buy it. Then build the HF adapter described in the *ARRL Handbook*, adjusting its oscillator frequency as required. This will allow you to see a high frequency signal on a low frequency 'scope, and the overall cost will be much less.

A personal note

I own and use everything I have discussed here-except an oscilloscope. Would anyone like to donate one to me (ha!)? 73

SPECIAL EVENT STATIONS

JUN 28–30

WATERTOWN, SD The Lake Area Radio Klub of Watertown SD, and the Huron ARC of Huron SD will operate KB0TAH at DeSmet SD from 1700 UTC–0200 UTC daily. Phone freq. will be 3.870, 7.265, 14.265, 21.340, and 28.340 MHz. CW operation will be 40 kHz up from the bottom of each band, 80–10 meters. For a certificate, send SASE to *Lake Area Radio Klub, P.O. Box 642, Watertown SD 57021-0642.* To obtain an unfolded certificate, supply a 9" x 12" envelope with two units of postage.

JUL 4–7

SAINT LOUIS, MO The Suburban Radio Club will operate WØDCW CW and phone, on the lower 25 kc of the General portion of the amateur bands, 10 AM–5 PM CDT. For a certificate, contact *Bill Coby KBØMWG, 4946 Pernod, St. Louis MO 63139-1252.*

JUL 6

DELTAVILLE, VA The Middlesex AR Group will operate Station AD4VI 1300 hrs–1900 hrs to commemorate the annual Deltaville Heritage Day. Freq.: lower General 80m–15m phone and CW, and Novice 10m phone. For a certificate, send a 9"x 12" SASE to *Peter Wright AD4VI, P.O. Box 1025, Deltaville VA 23043.*

JUL 8–9

BARABOO–MILWAUKEE, WI K9KYX/Circus Train Mobile will operate 1400 UTC–2030 UTC both days, from the Great Circus Train as it travels from Wisconsin's Circus World Museum to Milwaukee. The train will pull 20 double-length flat cars carrying more than 60 priceless, fully restored circus wagons for the Great Circus Parade which will occur the following Sunday. Operation will be on 20 or 40 meters, whichever band is in the best condition, around 7.240 or 14.240. There *may* be extended hours July 8th. For a certificate, send a 9" x 12" SASE with three units of first-class postage. SASE to *Don Evenson K9JYX, 401 11th St., Baraboo WI 53913.*

JUL 8–14

AUSTIN, TX Amateur Radio Operators affiliated with the American Assn. for Nude Recreation, the Naturist Soc., and the Federation of Canadian Naturists will observe the 21st annual N.A. Nude Awareness Celebration by operating Special Event Stations from naturist resorts, on the following freq.: 7.265, 14.265, 21.365, and 28.465 +/- QRM. For a personalized certificate, send QSL and 9" x 12" SASE to *Bob Redoutey KF5KF, P.O. Box 200812, Austin TX 78720-0812.*

JUL 13-14

SAN PEDRO, CA The United RAC and the Ft. MacArthur Military Museum Assn. will operate K6AA at the Ft. MacArthur Military Museum, 3601 South Gaffey St., 0800–2000 PDT July 13th, and 0800–1600 PDT, July 14th. Freq.: SSB—7.260, 14.280, 50.150, and 144.250 MHz. FM Voice—51.060 and 145.520 MHz. For a commemorative QSL card, send QSL and a 9" x 12" SASE to *United Radio Amateur Club, Los Angeles Maritime Museum, Berth 84–Foot of Sixth St., San Pedro CA 90731.*

JUL 17–22 & JUL 25–AUG 1

CAPE BRETON, NOVA SCOTIA, CANADA The West Island ARC of Montreal will operate from two locations on a DXpedition to Atlantic Canada. From 17–22 July a DXpedition to the Marconi Nat'l Historic Site in Cape Breton Nova Scotia will concentrate on 2-meter contacts with Europe. A CW beacon-type CQ will be transmitted on 144.020 MHz, with a reply sought on the same frequency. European hams are requested *NOT* to transmit on this frequency *UNLESS* the CQ is heard. From 25 July–1 Aug., a DXpedition to Seal Island off the southern tip of Nova Scotia will focus on a 2-meter Trans-Atlantic contact as described above, but using two separate systems, on 144.020 and 144.030 MHz. Operation will be on all bands from 160m to 70 cm (excluding 220 MHz), including the RS-10/11, RS-12/13, RS-15, AO-10 and AO-13 satellites. Special emphasis will be placed on participation in the worldwide IOTA (Islands On The Air) contest from 1200 UTX 27 July–1200 UTC 28 July. The callsign will include the suffix "CWI." For further info, contact *Fred Archibald VE2SEI at (514) 694-3441. Fax: (514) 630-4134; or E-mail: ARCHIBALD@NASH.PUBNIX.NET.CA;* or contact *Al Penney VO1NO at (902) 427-0550 Ext 3701; or (902) 876-2779.* QSL cards may be sent to *VE2CWI.*

JUL 20

CHAMBERSBURG, PA The Cumberland Valley ARC will operate W3ACH to commemorate the 132nd Anniversary of the Burning of Chambersburg PA by Confederate forces on July 30, 1864. Operation will be 1200Z–2100Z. Freq.: 3.870, 7.240, 14.250, and 147.12. For a certificate, send QSL and 9"x 12" SASE to *CVARC, P.O. Box 172, Chambersburg PA 17201.*

JUL 20-21

STRATFORD, NY The Fulton County Dr. Mahlon Loomis Committee will operate W2ZZJ to commemorate the 170th Anniversary of the birth of Dr. Mahlon Loomis, the American radio pioneer. Operation will be from 1300Z–2000Z on the General class phone portion of 75, 40, 20, and 15 meters, and on the Novice 10 meter phone band. Also on area 2-meter

FM Rptrs. For a parchment certificate and extensive literature, send QSL, contact number, and a #10 SASE (55¢) to *W2ZZJ, 5738 STHWY 29A, Stratford NY 13470.*

JUL 24–28

NANAIMO, BRITISH COLUMBIA, CANADA The Nanaimo ARS will operate CY7TUB 0001 UTC–2359 UTC, to celebrate the 30th Anniversary of the world famous Nanaimo to Vancouver Bathtub Race. Primary modes on HF (-160) will be SSB and CW. More info will be posted on the DX Packet Cluster. *Send QSL cards and an SASE to VE7NA.*

JULY 27–28

GREENVILLE, OH Station W8UMD will be sponsored by the Treaty City ARA in celebration of the Annie Oakley Parade/Festival. Operation will be July 27–28, 1300Z–2300Z, CW and phone, on General portions of the hamband. For a Certificate, QSL to *W8UMD, T.C.A.R.A., P.O. Box 91, Greenville OH 45331.*

JULY 27–29

OSHKOSH, WI Members of the Fox Cities ARC (Appleton WI) will operate W9ZL from the Experimental Aircraft Assn. Fly-In and Convention. Operation will be from "Pioneer Airport" adjacent to the EAA Aviation Museum. Listen on the General phone portions of the HF bands, as well as RTTY and CW, as conditions and operators permit. The club will also be giving "on grounds" convention info (no QSLs please) on 146.520 simplex. For an 8" x 10" picture certificate, send a proper QSL and SASE to *Wayne Pennings WD9FLJ, 913 N. Mason, Appleton WI 54914.*

LETTERS

Continued from page 62

in your head before you send. Say it aloud if you have to—sing it! Then use your hand key to make the sound you heard. If the rhythm or spacing is not quite right, try again until you are sending what you are hearing. Realize that, if not carefully sent, many characters can sound alike— "C" and "Y" for example. To make it clear, I tend to hold the final dah in the "Y" a little longer. It takes practice, like playing scales on the piano. Sit down with the latest copy of *73* and send Wayne's column on your practice oscillator. Don't try for speed, that will come. In fact, with consistent slow practice speed will creep up on you before you know it. Just keep a nice steady pace with clear characters and good spacing between. A little silence between characters and even more between words is no waste of time. It gives the other guy a chance to catch up and makes for greater accuracy with fewer repeats—nothing wastes more time than repeats.

The code was easy for me. I've a musical background—never met an instrument I couldn't play. The code is just a style of music (reminds me of the blues) and the hand key is just another instrument. This may be why I enjoy it so much. On the other hand, I know a fellow who is a fine RF engineer who could not carry a tune and cannot learn the code. He wanted to be a radio operator in the Army, but washed out and ended up being a technician.

The question I have is: Why should musical talent make me a superior radio operator? Why am I better qualified to operate the HF bands than a respected engineer with a tin ear? In the early days, when CW was the only game in town, the code requirements made sense. There is the myth that CW will get through when other methods fail. My experience has shown this to be baloney. Compared to AM, sure, but if it's hard to copy on SSB, then it's going to be tough on CW too.

I do CW for fun, but never would I want to impose my idea of fun on anyone else. Some will never learn code, others learn 13 wpm, pick up a mike and throw away the key. A few nut cases (like me) really like it.

I'd like to encourage all newcomers to give CW a try, but do it for yourself and not to be politically correct on the air. I hear many no-coders on the air say things like, "I'll start learning code as soon as the basketball season is over." This is a free country and there's no need to feel guilty about not wanting to learn code. If you learn it, learn it well and you'll find it can bring just a little bit of magic to ham radio.

Let's see, where did I put that key? ... Wayne

Radio Bookshop

Phone 800-274-7373 or 603-924-0058, FAX 603-924-8613, or see order form on page 88 for ordering information.

UE220 **The Easy Wire Antenna Handbook** by Dave Ingram K4TWJ. All of the needed dimensions for a full range of easy to build and erect "sky wires." $9.95

WGP87034 **All About Cubical Quad Antennas** by William Orr and Stuart Cowan "The Classic" on Quad design, theory, construction, operation. New feed and matching systems. New data. $11.95

TAB 3270P **Practical Antenna Handbook**–2nd edition by Jos. Carr. This 560-page book is a treasure. Starts with fundamentals, explains propagation of all kinds, and provides a ton of easy antenna projects. $26.95

AR4734 **ARRL Antenna Book.** Best and most highly regarded info on antenna fundamentals, transmission lines, design, and construction of wire antennas. $30.00

WGP87107 **All About Vertical Antennas** by William Orr Comprehensive coverage of amateur communications. $11.95

WGP87042 **Beam Antenna Handbook** by William Orr and Stuart Cowan. Everything you need to know about beam design, construction, and operation. $11.95

WGP87077 **Simple, Low-Cost Wire Antennas For Radio Amateurs** by Willliam Orr and Stuart Cowan. Low-cost, multi-band antennas; inexpensive beams, "invisible" antennas for hams in "tough" locations. $11.95

AR4661 **ARRL's Antennas & Techniques for Low-Band DXing** can be your ticket to low-band success. $20.00

ARRL Extra Class License Manual

The sixth edition of *The ARRL Extra Class License Manual* has been completely revised and updated to match the newest Amateur Extra Class (Element 4B) question pool, released by the Volunteer-Examiner Coordinators' Question Pool Committee in December 1995. The new questions will be used on Extra Class license exams starting July 1, 1996, and are expected to be used until the year 2000.

The ARRL Extra Class License Manual includes study material for every question in the question pool, and will help you pass the written exam required for the Extra license. It also provides operating hints to help you get on the air and enjoy some of the more "exotic" operating modes, such as Earth–Moon–Earth (EME), satellites, and amateur TV. *The ARRL Extra Class License Manual* is $12.00.

1996-1997 Repeater Directory

The American Radio Relay League has released the 25th Anniversary Edition of the *ARRL Repeater Directory*, a completely updated, pocket–sized collector's edition. Besides expanded listings for U.S. and foreign repeaters, you'll find greatly expanded propagation beacon listings, information on repeater operation, interference tracking, and use of the LiTZ system, among other things. Also included are names and addresses of ARRL officers, committee members, frequency coordinators, and a complete listing of ARRL Special Service Clubs, with meeting times and locations. All this and lots more in the *1996-1997 ARRL Repeater Directory* is $8.00 and is available from Radio Bookshop. (See page 88 for order form and S&H fees.)

HF band conditions are likely to be in the doldrums with the usual QRN and seasonal slump in DX activity; however, the HF bands will be open long after dark, and there will be lots of vacation-time mobile and portable activity, so all is not lost.

The Earth's magnetic field—hence ionosphere—is expected to be active between July 3rd and July 7th, and again on the 31st, with possible violent storms and even earthquakes and volcanic activity during these days.

The monthly chart anticipates the 10th, 17th, and 23rd to 25th to be Good days, but the remainder of the month shows trending conditions. Possible bright spots are potential VHF opportunities during the disturbed period mentioned earlier, supplemented by meteor-burst propagation from the Delta Aquarid meteor shower which begins on the 29th and lasts about 10 days.

Where 10m is shown, also check 12m. Where 15m is shown, check 17m too. Where 20m is shown, be sure to look at 17 as well. Always check the bands above and below the indicated bands for possible openings to the areas shown. Remember that DX is where you find it, and not always where it is predicted to be.

28 F-G	29 G-F	30 F-P	31 P			

10–12 meters

This is a daylight-only band this month, but may present openings to tropical areas as well as short-skip openings on the best days (G). During intense, sporadic E conditions (rare this month) bursts of strong signals can come and go unexpectedly. Stay alert.

15–17 meters

These bands could stay open into early evening hours with possibilities of transequatorial DX on Good (G) days and evenings. Signals seem to peak toward the west during afternoon and evening hours. Short-skip to 1,000 miles or so should be available on many days.

20 meters

This should be your main choice for DX-chasing. Because some areas of the world are dark and others are in daylight at the same time, you can expect dawn-to-dusk, and even later, DX opportunities on Good (G) days/nights. Short-skip will prevail to about 2,000 miles during the day, and further at night.

30–40 meters

You may find these bands quite noisy (QRN) during the daytime, due to the onset of thunderstorms this month, but they will be quieter during the nighttime hours. DX to your east will be the best before midnight, and best to your west before dawn. Choose Good (G) days for best chances of scoring a new country. Short-skip of 100–1,000 miles during the day, and 500–2,000 miles or so at night will prevail.

80 meters

You may find that 80 meters will provide DX on Good (G) nights, limited by thunderstorm activity. It may also provide short-skip openings of 200 miles or so during the day and 2,000 miles or more after dark.

160 meters

There will be *no* daytime openings here, due to a high absorption of signals, but it ought to provide skip to 1,000 miles or so after dark. Only rarely will you find DX, and only on Good (G) nights with low or no thunderstorm activity. Low-frequency static bursts, hundreds of miles in length, limit your summer operations. 73

MORE UPDATES

Poor Man's incorrect callsign

Sam Guccione wrote an article for us back in November of 1995 titled "Poor Man's Doppler." If you have been trying to reach him on the air, we're sorry that you haven't. His correct call sign is K3BY, **not** K3BYCC and the photographs used in his article were courtesy of N3JCP, **not** N3JGP.

Crystal–Controlled update

The November 1995 issue featured Mr. Frank Brumbaugh's article "Crystal–Controlled Audio Generator" for which we have a few corrections. Look to page 32 for these: column one, paragraph one, lines one and eight; please change "C13" to "C3". Column 3, last paragraph, lines 8 and 9, "constant frequency" should be straight line frequency, and in the same paragraph, lines 3 and 4, "constant capacity" wants to be "straight line capacity." One more thing: in the schematic, C11 should go from Q3 emitter to Q2 emitter.

440 Super-J Pole

In an effort to prevent confusion about the "440 Super J-Pole Antenna" article published in April's *73*, we offer this advice from author Marty Gammel KAØNAN: "Please connect the feedpoint as shown in the **photo**, not as the text described it. The center conductor *does* clamp to the short vertical element." 73

HAM RADIO FUN SECTION

On the cover: Ten-Tec provided the cover shot this month of their Model 1220 2 meter FM tranceiver kit. Included in the photo is their 1222 power amplifier kit which is available as an accessory.

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromat Way Ltd. of Hancock NH.

Contract: Even the most cursory glance at this text is sufficient to bind you, morally and legally, to take a kid (or kids) along on Field Day, get 'em fired up on amateur radio, and then help 'em gel started toward a license. You'll feel good about yourself and our legal deoartment won't have to hassle you.

NEVER SAY DIE

Wayne Green W2NSD/1

As a salve for those readers who are monomaniacal about the hobby and don't want to read or know about anything else, my editorial this month is strictly ham oriented. This is frustrating because there have been some amazing non-ham or semi-ham things taking place that I think many of you would enjoy reading about. Like a fantastic $5 book I've found that explains an ultra-simple way anyone can find out what they're allergic to, and thus help them get rid of arthritis, multiple sclerosis, and a bunch of other weak immune system miseries (like cancer).

Then there was my four-hour guest shot on the Art Bell W6OBB talk radio show. The thousands of letters and orders for my booklets resulting has dominated my life for the last month. My talking about amateur radio has resulted in hundreds of new subscribers. It's had my copy and folding machines running overtime, with me data entering the booklet and subscription orders, then assembling and mailing my booklets. Whew!

In order to keep this month's column hammy I've robbed some of the stuff from my 84 pages of editorials not yet published in *73* booklet, making it now editorials mostly not yet published in *73*.

News Flash: Money Talks

Many nervous Techs have been asking me what I think of the move by commercial interests to buy our 144 and 450 MHz bands. My answer is simple: Money talks when you're dealing with politicians. Even the FCC (as well as Congress) was amazed at how much the spectrum turned out to be worth when they put it up for auction. Mmm, billions! More money to spend! More pork! Let's see now, what social programs can we cook up to take care of this bonanza? If you're not up on how Congress works, there are a couple excellent books on my $5 recommended reading list that will enlighten and disgust you. Hey, they might even be enough to get you to start thinking. Well, maybe not. We seem to have a lot of hard corpse cases out there in hamland.

However, there's one other commodity politicians understand, and remember that the FCC Commissioners are all political appointees. Politicians understand votes.

That's why, when I got fed up with the idiotic repeater restrictions Prose Walker engineered, I organized a hearing before the Commissioners to get our repeater rules changed. I not only brought in a parade of carefully rehearsed repeater group representatives to testify, I also waved a thick stack of petitions at the Commissioners. The repeater groups had collected thousands of signatures at hamfests and club meetings, and it was these, more than reason, that carried the day. Reason is not a powerful weapon when dealing with politicians. Anyway, the result was that we brought about the largest bunch of rule changes in the history of the FCC. We even helped trigger not just the deregulation of amateur radio, but also the other services.

Anticipating just such an attack as we are now facing from the moneyed big boys, I've recently proposed in my editorials that every ham club make it project number one to get a club member elected to their state legislature. We need the clout ham legislators can provide in every state, and not just to help us fight off commercial raids on our bands, but also to kill tower restrictions and to help implement my own pet project: an eight-year course in electronics, communications and computers in every school in the country, grades 5-12. Ham legislators also will have the ear and eye of the media, which will also help give us some desperately needed political clout.

Two meters is the most used of all out ham bands, by a wide margin. What will the loss of two meters (and 450) mean to us? Well, that would pretty much put over half our hams out of business. The Tech half, which has been brainwashed into believing that learning the code is totally beyond their ability, will have few practical options. Thus, in eight to ten years, when their licenses aren't renewed, the FCC figures will drop precipitously.

Oh, a few will manage to overcome their mental block about the code and join us on the low bands. Fewer still will move to 50 or 222 MHz.

With all those satellites up there providing dependable communications, there's no longer much commercial interest in our HF bands, so we'll probably hold them until the few of us that are left die off. Frankly, I expected to see our virtually unused microwave bands be the first to go. These are prime targets for the proposed new satellite consumer services.

Meanwhile, I'll be checking the ham club newsletters for signs of activity in backing club members in a run for state legislatures, at least with as much enthusiasm as supporting Walk-A-Thons. We sure don't have any money, so all we've got are votes to work with. And that means playing the politics game. Or else.

Atlanta Hamfest!

Well, it seemed more like a computerfest, looking at the exhibits. And more like a geriatric convention, looking at the attendees, what few there were of them. This is terrible!

Atlanta is the hub of the whole southeastern US, yet I doubt if a thousand hams bothered to turn out for the hamfest. I went around the place counting heads several times during the day. I came up with between 600 and 700 on most sweeps, and that included the out-of-the-way commercial exhibit area, the three talk rooms and the flea market. I saw almost no youngsters all day.

I checked the talks every hour to see what kind of crowds they were pulling. Packet: zero! Repeaters: one. DXCC pulled a big four. The ARRL meeting pulled a whopping nine. Antennas had five. Beginners had four. The two DXpedition talks pulled 17, the biggest crowd of the hamfest — except for my talk, which was scheduled at the close of the show, when everyone was hot and tired, and pulled 48. There was no mike, so I had to do the best I could over the noise of the big fans (air conditioning in sizzling Atlanta? Har-de-har). The hamfest was held in a dirty old Sears warehouse.

Now here's a show that should have pulled in hams from all over the south. They should have had at least 15-20,000 hams there. They should have had the whole ham industry exhibiting. They should have had top-notch entertaining speakers to help pull in the crowds. So what has happened? Is ham radio dying in the South, or is this the sad result of local clubs refusing to cooperate for the good of the hobby?

We're at a time when we need all of the cooperation we can get between clubs. With the threatened loss of our no-code bands, and with well over half our hams being Novices or Techs, the last thing we need is foot-shooting rivalries.

The club couldn't afford to bring me down to talk, so I paid my own (and Sherry's) way, hotel, rental car, and meals. What I found was a well-lit flea market area packed with software sellers (mostly games), and the commercial exhibitors way off in a dimly-lit back area, where

LETTERS

From the Ham Shack

David Plett 3A2LZ. Greetings from a US ham in Monaco. I am strongly opposed to the idea of upgrading senior citizens, as an article proposed. Here's why. The basic purpose of amateur radio is to develop a pool of people trained and skilled in electronics and communications. Reducing the technical knowledge and requirements is contrary to this goal. Math requirements certainly should not be reduced. In fact, they probably should be increased. You are not required to do everything longhand to the 19th decimal place. "Filling in the blanks" and basic calculator functions suffice. The correct answers are easy enough to memorize. I memorized the Advanced and Extra theory questions in three days while driving around central Florida during a short stay in the US in 1993. The math included is part and parcel of basic technical requirements for any higher-class amateur radio license in any country I know. I am against favoritism. This is not in a spirit of cruelty, or to say that experience does not count or that we should not try to help those who have difficulty with the theory. However, the fact that somebody is a good "on-air" ham or a nice guy should not be an excuse for allowing technically unqualified people to be given higher licenses. The better response is to help those with difficulties. Those of us who have an easier time with theory, code, or regulations (my most difficult area) have an obligation to help others. It has been suggested that the US technical requirements are higher than those generally used in Europe. This is not so. Most US hams I speak to find the Advanced test to be the most difficult technically. The Extra exam covers mostly VE matters. From my exposure to European hams, the technical exam for the entry-level license (VHF only), where there is no Novice license, covers approximately the same material as the Novice through Advanced US tests. However, it is not always "multiple-guess" and often requires one to illustrate and analyze circuits without having seen them previously in the same form. The CW test usually requires both sending and receiving. The receiving test is even more difficult since it is usually not multiple-choice. The transmit test sometimes requires up to five minutes of text be sent error-free. We need to keep high technical standards for amateur radio licenses; not to keep people out, but to fulfill the obligation to train people for the real world of electronics today.

The Smithsonian Answers

Bernard S. Finn, Curator, Electrical Collections, Smithsonian. In recent articles in the magazine *73 Amateur Radio Today,* John Wagner has made several statements about the historical role of Nikola Tesla, about the Smithsonian's treatment of Tesla, and about Mr. Wagner's communications with the Smithsonian. Not surprisingly, my views are somewhat different from his, as reflected in the following comments.

I. The historical role of Tesla

There is little question that Tesla was a genius, whose fertile mind generated a number of ideas at the cutting edge of the electrical technology of his day. Indeed, plausible arguments are made that some of his concepts can be useful in investigating phenomena that we still don't understand. However, like many geniuses, Tesla was a loner. He had difficulty working with other engineers—whether in explaining his ideas to them or in considering their criticisms. The unfortunate consequence of this was that his impact on practical technical developments was severely impaired. This does not make him less interesting; indeed, for those of us who are concerned with the roots of creativity, it makes him, if anything, more so. But it does mean that we should be careful in what we claim were the consequences of his activities.

Tesla's concept of the rotating field was clearly innovative and was recognized as such by George Westinghouse when he negotiated to purchase the patents in 1888/9. But to claim, in Mr. Wagner's words, that "he created the polyphase alternating current system of motors and generators that powers our world" ignores contemporary European systems that relied on the work of Pacinotti, Brown, Dobrowolsky, Wenstrom, and also Westinghouse engineers who, with Tesla's help, translated those patents into practical electrical technology.

It also ignores the complexity of the history of electric power systems. A starting point might arguably be the development of the self-excited dynamo in the 1860s (Siemens, Wheatstone) which was efficient enough to make lighting and power systems (both AC and DC) practical, especially with better magnetic design in the 1870s (Gramme and others). That made it feasible for arc lighting, incandescent lighting, street railways, and other applications to become widely available. The AC transformer in the mid-1880s (Gaulard, Gibbs, Blathy, Zipernowski) made possible long-distance transmission (though this could also be done, with less efficiency, for both AC and DC using motor-generator sets). Multiphase AC operation, with which Tesla is associated, made transmission more efficient; it also gave us an AC motor. More recently, development of means for transforming DC has meant even more efficient means of long-distance transmission at very high voltages.

Incidentally, Edison's role in this particular sequence is modest, being confined primarily to the design of a more efficient DC generator.

Tesla is given credit by Mr. Wagner for "every essential of radio." This statement is presumably based on his patents for basic tuning concepts. Eventually the US Supreme Court held that these, together with patents of John Stone and Oliver Lodge, anticipated those of Marconi. But Tesla was ineffective in promoting any system of his own, and although it is intriguing to think that his work may have had a significant impact on others, good historical evidence of that is lacking. Starting from the experiments of Hertz, it was Marconi, Stone, De Forest, Fessenden, and Braun, among others, who developed practical radio technology. They were aware of some of the details of what Tesla was doing, but, as far as we are able to discern, they came to their own basic ideas independent of him. We can therefore marvel at Tesla's early understanding and articulation of some important concepts, but should beware of extending him credit for everything that followed.

II. The Smithsonian's treatment of Tesla

Although the Smithsonian is a large enterprise, so also is the scope of our mandate. Our museums cover a vast range of history, culture, and technology. Our resources—in space, money, collections, and personnel—are limited. Because we cannot address everything in our exhibits, we generally take one of two approaches. We may do a broad survey—as presently is the case with the "Information Age"—where individual subjects and people are given relatively brief mention. Thus, in that exhibit, in a section on wireless and radio, Tesla shares space with Hertz, Lodge, Marconi, De Forest, Armstrong, and others. The other approach is to do a smaller exhibit with a focus on a particular topic or person. Thus, in "Lighting a Revolution," we pay special attention to the incandescent lamp and to Edison. Other people are included, most notably those who were directly involved in that development—like Brush, Farmer, Thomson and Swan. We pay less attention to subjects like the competing gas light technology or the development of later distribution systems.

In "Lighting a Revolution," we try to describe the origins of Edison's work and as well as its impact. Our concern is with the light bulb. We do not claim, as Mr. Wagner suggests, that Edison "invented DC electricity" or that he "invented AC electricity and harnessed Niagara Falls." We argue that, because of the popularity of the incandescent lighting, there was an incentive to develop large-scale generating systems (at the same time granting that there were other factors, including street railways and electrochemical processes). We allow this argument to lead us to say that the light bulb was a key element encouraging the creation of the Niagara Falls station, not that "he made the Niagara project possible." There is no claim that Edison had anything directly to do with that station. Indeed, because we use Niagara Falls simply as

an indication of America's commitment to a new electrical age, we, rightly or wrongly, don't describe it in any detail.

We do, however, include a Tesla motor and a nameplate from a Niagara Falls dynamo (we have the dynamo itself in our collection, but at 85 tons it would not easily fit in the exhibit). There is a picture of Tesla and a short biographical sketch (which admittedly are not prominently displayed).

Mr. Wagner notes that this exhibit was sponsored in part by the Thomas Alva Edison Foundation (actually through an International Committee for the Centennial of the Electric Light). We are very sensitive to the problems potentially associated with sponsorship, no matter where it comes from. Unfortunately, exhibits cost money, and it is necessary in most cases for us to seek outside help—which usually comes from people who are interested in the subject we want to treat. Realizing this, we *insist* that the money comes without strings, that we are the ones who determine what objects and what text are included. In this particular case I know that the committee exercised no influence over the content of the exhibit.

In the catalog of the exhibit, mentioned by Mr. Wagner, we included the biographical sketch of Tesla described above. A revised edition specifically credits his patents as the basis for the Niagara generators.

Several years ago we organized a one-case exhibit for a special event at the National Academy of Sciences. Afterwards we displayed it for several months near the Niagara Falls nameplate mentioned above. It was well lit and was definitely not "in a darkened hallway next to the men's room," as stated in Mr. Wagner's article.

We have long been of Mr. Wagner's view that a more extended study of Tesla would be appropriate for an exhibit. Unfortunately, we have virtually no artifacts for such an effort beyond those already in "Lighting a Revolution." We obtained a small grant to explore the possibilities of a joint endeavor with the Tesla Museum in Belgrade, where virtually all the surviving Tesla material is preserved. They were excited about the possibilities and some tentative agreements were made. We hoped to have something together by 1993, the centennial of the Tesla displays at the Columbian Exhibition in Chicago. Tragic political events with which all of us are familiar intervened, and the project was put on hold. Recent developments hold promise that we may be able to begin again, assuming that further funding can be found.

I should add, however, that when we do such an exhibit it will not be a simple celebratory event of the sort Mr. Wagner seems to envision, any more than "Lighting a Revolution" or the "Information Age" are. This is a history *museum*; in it we try to promote a better understanding of people and events by presenting them in the context of their times. The complexity and richness of personalities like Tesla and Edison deserve no less.

Meanwhile, when we make some modifications in the "Lighting" exhibit next year to include more recent developments in lamp technology, we plan to expand our treatment of AC systems, which will allow us to say more about Tesla's contributions.

III. John Wagner and the Smithsonian

For several years Mr. Wagner has been attempting to have Tesla better represented in this museum. He is not alone in this desire (nor is Tesla the only person with advocates) and we appreciate his efforts. In the process, he has no doubt encouraged a number of people to learn about this remarkable man, and he has encouraged us in our own researches.

I have been especially impressed by the fact that he has gotten his third-grade students to learn about Tesla. They have been articulate in their letters to the Smithsonian and they have apparently been sufficiently persuasive to corporation presidents to elicit $50 and $100 contributions to pay for the casting of a bust of Tesla which had been sculpted by the father of one of the students. Certainly this is a good thing for them to do—as long as they realize that we may have good reasons for not automatically acceding to their demands that this bust then be exhibited at the Smithsonian.

As Mr. Wagner notes, the bust was offered to one or two other museums and then to us. The Smithsonian has a policy of not accepting busts unless they are made from life and we declined the offer. Furthermore, there was no particular reason to accept it, since we have no gallery of inventors or other context for it.

We do have a bust of Edison, as Mr. Wagner mentions. It was made from life, by a phrenologist who wanted to examine the bumps and hollows on Edison's head—making it doubly interesting. It is exhibited (not near Tesla's motor) as part of an attempt to demonstrate how Edison had excited public admiration even before he started work on the electric light; this was an important factor when he looked for funding for his investigations.

In sum, there is no vendetta or conspiracy within the Smithsonian against Nikola Tesla. We currently have an exhibit featuring Edison's electric light—because we have excellent material and an interesting story to tell. Circumstances in the future may lead us to treat other Americans of that pioneering generation, like Charles Proteus Steinmetz, or Elihu Thomson, or William Stanley. We had specific plans to do so for Nikola Tesla. At the moment these have been thwarted, but we hope we will be able to resume the endeavor before long.

John Uscinowski KE2O (ex-W2JMR). I have been licensed since 1935. I built my own test equipment, transmitter, and receiver. I remember going to Cortlandt Street to Harrison Radio, Leeds, and Blan The Radio Man to buy parts. Since I lived in Yonkers, it was a nickel on the trolley and a nickel on the Van Cortlandt subway. Please keep plugging away, steering us back toward basics.

It was also a nickel via the BMT subway from Brooklyn, so I spent a lot of time shopping the radio stores of Cortlandt Street back in the 1930s. And Radio, Wire, Television, later named Lafayette Radio, 100 Sixth Avenue, was a wonderful source of parts. Then there was the WWI surplus stuff on Fulton Street ... Wayne.

Alexander Dumble. Your recent guest appearance on the Art Bell Show was the best show of the entire series to date. Your stands on technology and the philosophical applications give a posture of hope and accomplishment; and I am one who dearly appreciates what you've brought to the arena. The cold fusion phenomena has captured my attention, and I want to build a working model. In my circle of friends we have built and operated wind-powered electrical generators, and these devices are encouraging. However, the thermal potential of cold fusion cells really sounds wonderful. So getting information to start experiments is now paramount.

Your presentation concerning Bob Beck was delightful to hear. Bob has been a mentor to me and many others for the past decade, going back to the old Psychotronics Club, here in the LA area. The club is no longer going, but the legacy that Bob has imparted is very much alive and well. Personally, I have assembled many Beck devices, and so far have built thirty of the "plant stimulators." I was an original subscriber to *Byte*. Despite all the floods and earthquakes, these original issues of *Byte* are still here with me and treasured. Thank you, sir, for what you have brought to the world.

Wow! And just when I thought I was beating Rodney Dangerfield in the "don't get no respect" race. Well, maybe this counters a nasty note I got from some sniveling lily-livered yellow-bellied Philadelphia coward who didn't have the guts to sign his name ... Wayne.

John Schultz W4FA. Shame on you for printing that article on antennas using copper foil tape without checking things out. The 3M tapes mentioned are extremely difficult to find and the *only* distributor for them in NC has a $75 minimum order.

Anyone else have trouble finding the foil tape? If so, make an omelet by buying $75 worth and running an ad to sell the stuff to hams retail. Look on any problem as a golden (well, copper) opportunity ... Wayne.

QRX . . .

FCC Criticizes Consumer Equipment

The FCC recently released a statement saying that most Radio Frequency Interference (RFI) problems are caused by faulty design of consumer electronics equipment such as VCRs, telephones, and TVs. The statement is good news for hams who now have the FCC on record as agreeing with what many hams have maintained for years. Such statements will be of great value in fighting RFI complaints and defending hams against capricious lawsuits which some angry consumer gear owners have initiated.

Meanwhile, the FCC has given up on its pilot project, which tasked consumer electronics service shops with evaluating RFI complaints. The Tampa FCC began the project in 1994 but only one shop was ever certified and its spokesman concluded that most problems were caused by unlicensed transmitters using illegal power. Also, it was never settled as to who would pay for the shop's services. Most consumers were unwilling to pay to have their RFI evaluated. Reportedly, the FCC is no longer handling any RFI complaints and is advising consumers who complain to direct their comments to the Electronics Industries Association, a group that represents equipment manufacturers.

TNX Billy Williams N4UF, *Balanced Modulator*, North Florida Amateur Radio Society's newsletter.

Pretty Sneaky

The April OH-KY-IN ARS foxhunt was one of deception—the fox, Dick WB4SUV, had taped a quarter-wave dipole to the bottom side of a fishing pole. The coax ran through the center of a bamboo prop for the pole. The batteries and transmitter running 50 watts were located inside an adjacent tackle box with a see-through cover, filled with fishing lures. The equipment was set up under the new Central Bridge on the Kentucky side of the river, and included two volunteer fishermen. The high power on the water's edge created many reflections on both sides of the river, along with a reported 100 dB attenuation needed two miles away in Devou Park. The sniffing part of the hunt was interesting, as both teams avoided disturbing the fishermen!

TNX Dick WB4SUV, *The Q-Fiver*, official newsletter of the OH-KY-IN Amateur Radio Society.

Amateur Radio Called an "Invaluable" Resource

A powerful late winter storm triggered severe thunderstorms, tornadoes and up to golf-ball-size hail over central and south Alabama. The National Weather Service said it issued 48 tornado and severe thunderstorm warnings during the afternoon and evening of March 18, 1996, "So many warnings that we overwhelmed the media in some situations," said Brian Peters WD4EPR, a Weather Service meteorologist in Alabaster.

At the Weather Service Forecast Office in Alabaster, Skywarn teams went on duty in mid-afternoon, opening nets on 2 meters, 440 MHz and 220 MHz, and remained there for nearly six hours. Amateurs manning the Net Control posts described the outbreak as one of the most intense in recent history, with severe weather occurring in several parts of their coverage area simultaneously. As powerful thunderstorms approached central Alabama from the west during the afternoon, radio amateurs began reporting damaging winds, hail, heavy lightning, and torrential rains on W4CUE, the Birmingham Amateur Radio Club's 146.880 MHz repeater. Amateurs operating a separate Skywarn Net in Hueytown in west Jefferson County assisted by turning in reports they were receiving. Weather Service forecasters listened closely to storm spotters and compared their information to the data being fed by Doppler radar.

While severe thunderstorms were pounding Jefferson and Shelby Counties, heavy thunderstorms began developing almost explosively in a line stretching from Birmingham south to near Montgomery; at one point, at least six counties were under warnings at the same time.

Radio amateurs activated Skywarn Nets in Montgomery, after getting advance warning from hams at the Alabaster Forecast Office who were using a recently installed 220 MHz link, connected to the N4PHP 220 MHz repeater in Shelby County. Numerous severe thunderstorm and tornado warnings were read over the link, sometimes giving Montgomery Skywarn teams their first notice that a warning was being issued for their area.

Peters said radio amateurs did a fabulous job. "I was amazed at the reports coming from hams all over the state and how well the hams were working together. It used to be that hams gave us reports from just the local area, but they were giving us information from Tuscaloosa, Fayette, Monroe County, and Montgomery.

"Amateur radio proved its worth again as an invaluable source for confirmation of weather events." Peters praised the speed with which amateurs relayed severe weather reports to the Weather Service. "We were getting reports from a bunch of different places and, nine times out of ten, the first reports were coming from hams."

Amateurs in the Montgomery area provided real-time observations of a funnel cloud north of the city and later reported a tornado on the ground. The tornado first touched down in Elmore County and then moved into Tallapoosa County, remaining on the ground for 30 miles, Peters said. In Tallapoosa County, the tornado hit a marina on Lake Martin and caused heavy damage to mobile home parks.

The ARRL's Alabama Section Manager, Tom Moore KL7Q, of Salem, was actively involved in storm spotting in east Alabama. "We were closely following the Montgomery activity that tracked across Elmore and Tallapoosa Counties. We had a live sighting of the tornado for several minutes before it hit the marina and Jackson's Gap, and several other severe thunderstorms down as far as Lee and Chambers County," Moore said.

Injuries were reported in Lowndes County, southwest of Montgomery, and more than 60 families were left homeless by the storms.

Peters said being within earshot of amateur radio proved handy to meteorologists analyzing Doppler radar displays of the storms. "I noticed that the staff every once in a while would hear words like 'golf ball.' Everybody at the radar console would get quiet and listen to what was coming in over the amateur radios."

A Skywarn team member who monitored emergency frequencies during the outbreak praised the efforts of his fellow hams. "This was the best Skywarn operation I've heard yet, on the part of the volunteers running the nets and on the part of the general ham community in providing timely, useful information," said Jim Smiley KE4CAP, of Alabaster.

Amateurs serving as Net Controls in Alabaster included Rick Kimbrell KC4RNF (ARRL Alabama Section's Emergency Coordinator), John Simons KC4UCP, Mark Parmley WA4UHC, and David Black KB4KCH.

Skywarn Nets were also active throughout east and west Alabama, including Tuscaloosa, Calhoun, St. Clair, Blount, Chilton, Tallapoosa, and Talladega Counties. In east Alabama, the Salem Hill Skywarn Net had an estimated 44 check-ins. Amateurs also staffed the Birmingham-Jefferson County EMA headquarters, assisting with damage reports.

Amateurs running Net Control Posts praised the quality of reports received from spotters in the field. On Birmingham's 146.880 MHz repeater, numerous hail reports were received from hams who gave specific size and location information along with wind speed estimates and other pertinent data.

Rick Kimbrell called the episode a test of nerves, hearing, coordination, organizing skills, and writing speed. "I thought the nets ran very well," Kimbrell said. "I was really pleased to see and experience working with the Montgomery group and the link that has been established. I thought it worked great."

The March 18th emergency marked at least the third time radio amateurs have set up Skywarn Nets for the Weather Service in 1996. Ironically, the March 18th storms forced a change in plans for Peters, who had been scheduled to lead a Skywarn training class for amateurs in Montgomery that evening. When the storms broke out, Peters canceled his appearance and remained at the Alabaster Forecast Office instead, manning one of the Doppler display consoles and analyzing wind patterns. Kimbrell, who had planned to accompany Peters to the Montgomery meeting, assisted with Skywarn Net Control duties instead, remaining on the air for nearly five hours.

From an article by David Black KB4KCH, ARRL Alabama Section Public Information Officer, in the April 1996 issue of *The BirmingHAM*, Official Publication of the Birmingham Amateur Radio Club.

It's a Fashion Statement

The "typical" ham:

- Wears button-up shirts, usually done up to the collar button but *never* undone below the second button.
- Wears an undershirt, even on hot, humid days.
- Wears polyester pants (usually too short).
- Wears pants revealing argyle socks and well-worn, outdated shoes.

• Has at least two writing implements in breast pocket of shirt.

• Has a digital watch, normally with two time zones (one of which is set to GMT), synchronized to the second with WWV or CHU.

• Is at either extreme of the body-weight spectrum.

• Wears glasses—even those who should only wear glasses for reading will actually wear them all the time.

• Has a wallet hopelessly overstuffed with pieces of paper of little or no importance.

• Has hair that's short and/or gray and/or thinning, devoid of style and probably not as clean as it should be.

• Has a handie with the "extra capacity" NiCd battery pack and the "Mega-gainer" antenna which serves to poke you in the face (or other, equally sensitive, body areas) when it is swung around.

• Uses Q-codes even in casual conversation.

• Wears a plastic name badge with the callsign bigger than the name.

Your Car's a Statement Too

The "typical" ham's car:

• Is typically, but not always, purchased used, with careful attention paid to large, flat horizontal areas of metal.

• Must have automatic transmission so that something as trivial as operating the vehicle does not interfere with a "QSO."

• Has lots of leg room so the driver can operate iambic paddles strapped to his calves.

• Has the ashtray removed to allow more room for radio equipment.

• Has loose wires visible either under the dashboard or in unusual place(s).

• Back seat contains the following: old copies of ham magazines; current copies of ham magazines; spare wire mag-mount; butane-powered soldering iron; solder; empty cigarette packs; parts of various antennas; SWR bridge; literature about new radios; more copies of old ham magazines.

• Will sport at least one of these bumper stickers:

ICOM–discover the quality
KENWOOD Amateur Radio
Yaesu Communications Equipment
Amateur Radio Spoken Here
Dayton HamVention 19__
Amateurs Do It 'Til Their Giga-hertz!
Hams Do It With Greater Frequency!
This Car Climbed Mount Washington

• Mechanics can easily identify a "ham" car by looking under the hood. Large wires lead mysteriously from the battery, which is usually about 875CCA, into the cockpit of the car. Careful attention has been paid to installing resistor-spark plugs and RFI suppression wires and ignition components. Special ingenious modifications have been made to the battery box to allow the installation of this *huge* battery—often involving bungee cords and bent pieces of sheet metal. The alternator is either new or has been recently replaced with a 100A unit.

• Bristles with antennas of differing lengths—some of these antennas look like big marshmallows on nine-foot sticks ... and at least one of them isn't even connected to a radio!

• License plate is callsign, of course.

Lifted from *NOARS LOG*, Official Publication of the Northern Ohio Amateur Radio Society.

Add These to Your "Computerspeak" Glossary:

ATTENUATE: Response to a cannibal who's eaten the very best and asks you to rate it for him.

AUTOMATIC CHECK: The one you write every month to your software supplier.

AUTO-ANSWER: Similar to "Dial-a-Prayer," but instead of a clergyman you get Mr. Goodwrench.

AUTO-REPEAT: A key which, when held down, when held down, when held down ...

AUXILIARY MEMORY: What you go to when she doesn't believe you were working late at the office, e.g. "The train was hijacked to Cuba."

BACKWARD RECOVERY: Clintonomics.

BADGE READER: Convention-goer who gets off on reading "Hi, I'm ... " badges.

BAGBITING: What happens when you don't unwrap your sandwich.

BANKS: Quiet, air-conditioned places where your salary is automatically transferred to peripheral salesmen.

BAR CODE SCANNER: A bouncer who checks the crowd for jackets and ties.

BARREL PRINTER: The guy who writes XXX on whiskey kegs.

BASIC: Something so "simple" you need a computer to understand it.

BATCH: A minor gripe.

BATCH PROCESSING: Cleaning up a batch so you can say it in mixed company.

BAUD RATE: Fee charged by loose women; usually $5.00 and up. *(Ed. note—how does he know that?)*

BELL LABS: Large black retriever dogs that go "Ding-a-ling!" instead of "Bow wow!"

BENCHMARK: Painful creases pressed into chips from sitting for long periods on park benches.

BI-DIRECTIONAL: A computerist who swings both ways.

BINARY: A little yellow bird that waves instead of whistles.

BINARY FILE: A whole row of them.

Build the QUAD-12 Personal Datalogger

Mike Gray N8KDD
1680 Cooley Lake Road
Milford MI 48381

There are several peripherals capable of converting a personal computer to a data acquisition system, but none that I know of are well suited for a laptop computer, and all of them are expensive. This quick project will be easy to assemble and to use. It's based on the new MAX186 Analog-to-Digital (A-D) converter from Maxim. You'll need only a few support components to complete the package. It's small, rugged, reliable, flexible, and cheap. Perhaps best of all, it doesn't need a battery, as the PC printer port supplies what little power it needs. The entire circuit fits in a DB-25 connector shell, including a terminal strip for connections to your various inputs.

What can you do with an A-D converter? An A-D converter lets you get information from the "outside world" into your computer. It seems that everyone has his own unique need for data acquisition. A-D converters are used in astronomy, seismology, plant growth research, and a host of other applications. An A-D converter can monitor battery voltages, RF power levels, fluid levels and pressures—practically everything can be monitored with the proper sensor. Most folks want to record temperature; this is easily accomplished with an LMØ4 temperature sensor.

Circuit operation

The easiest way to understand the operation in this configuration is to follow the BASIC program listed in the sidebar while referring to the schematic (**Fig. 1**). In order to understand the circuit operation fully, you need a timing chart. You can get a data book from Maxim and trace the logic for each pin, then change the mode of operation once you know how it works.

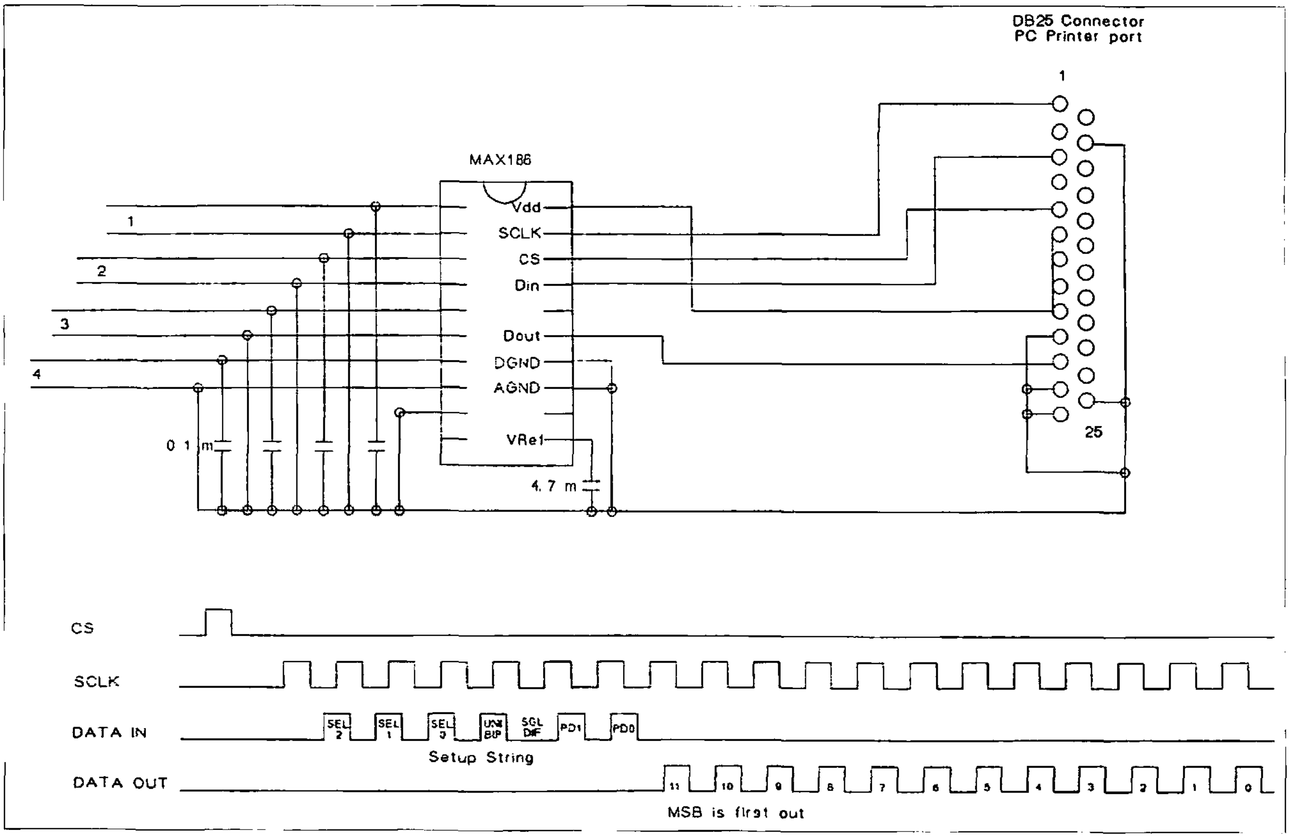

Fig. 1. Schematic diagram and initialization timing diagram for the Datalogger.

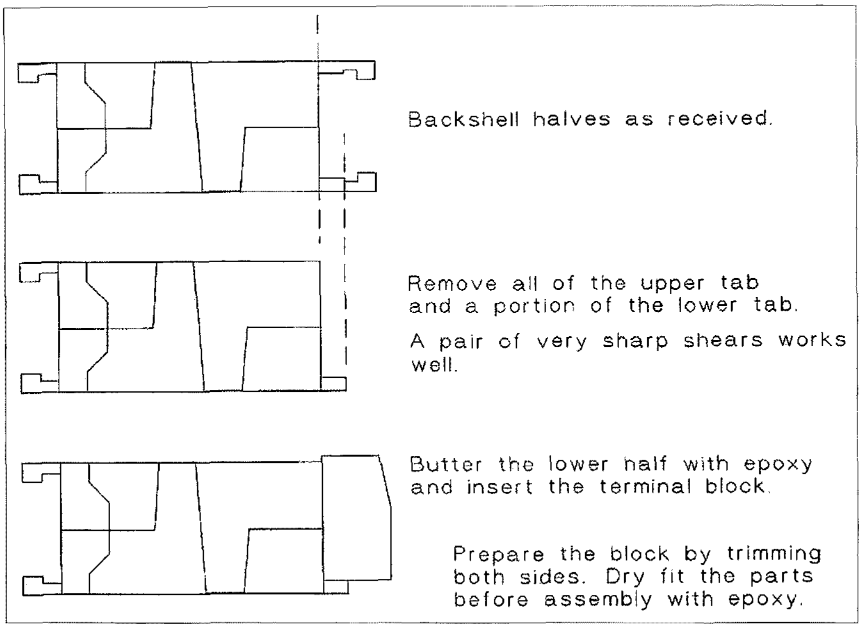

Fig. 2. Modifying the DB-25 backshell to allow mounting of the terminal strip.

Although the chip has eight analog input channels, this project uses only four so it'll fit neatly within a DB-25 backshell. The channels are configured as pseudo-differential with the low pins tied to a common ground. Most measurement systems share a ground anyway, so this arrangement will work well unless there is a difference in ground potential somewhere between the computer and the transducers. I've seen this happen only in automotive applications where the computer is being charged through the lighter socket. Lighter sockets are typically grounded to the body metal, which has a ground potential about 300 mV above engine ground. If the transducers are grounded at the engine block, you have a 300 mV error. The error changes as a function of charging current. If you run the computer on its internal battery you will have no problems with ground loops.

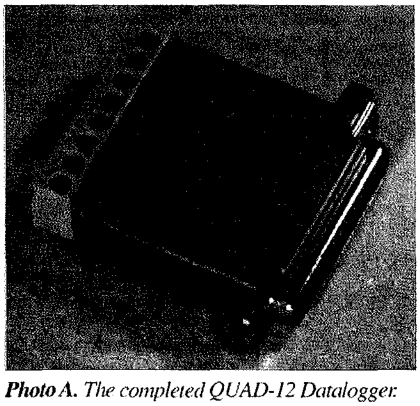

***Photo A.** The completed QUAD-12 Datalogger.*

The 0.1 µF surface mount capacitors (C1-C4) on each input channel form crude anti-aliasing filters. They help prevent high-frequency noise from influencing the data when sampled at a relatively low rate. The MAX186 has a high input impedance. Without the capacitors, an open channel can appear very active due to static charges or electric fields.

Software

The BASIC listing in the sidebar on page 15 shows the minimum code required to make the QUAD-12 work. You can insert it in your own application or use it just the way it is. The program simply causes the MAX186 to scan the four analog channels and print the conversion result to the screen. The source code is specific to PowerBASIC™. You may need to change the syntax or function names slightly to make it work with another version of BASIC.

After devising several application-specific programs, I wrote a generic data acquisition program for my needs. It has many of the features included in the high priced engineering software, like color graphics and mx+B scaling. It requires a 386 processor and VGA graphics. The Datalogger software is available with the complete kit of parts, or with the bare board. Check the listing at the end of this article.

Construction

The terminal block is glued into the backshell. Most epoxies take several hours to cure, so it makes sense to start by assembling the shell first, allowing the epoxy to cure while you assemble the other components.

Using a sturdy pair of sharp scissors, cut the backshell tabs according to **Fig. 2.** Cut the small studs from the bottom of the backshell with a sharp knife or flush cutters. I've found that the flush cutters work best. Trim the sides of the terminal block until it fits snugly into the backshell. When you are happy with the fit, apply some epoxy to both parts and clamp them in place until the glue is cured. Trim the circuit board with a file or grinder. The board supplied with the kit is a little larger than it needs to be, due to an artifact of the manufacturing process. The board fits snugly between the pins of the DB-25 connector.

Solder all five surface mount capacitors to the board. If you have never installed a surface mount component, don't be intimidated—it's really quite easy. Pre-tin one pad with enough solder to form a bead slightly larger than the end of the component. Position the component, apply a little pressure, and reflow the solder until it wicks up the side. Solder the other pad, then check your work. If the solder joint doesn't shine, add a little solder. Once you get a feel for how much solder to pre-tin the board with, you won't need to resolder any joints. All it takes is a little practice.

Bend the pins on the A-D converter (IC-1) outward until they are horizontal. Trim the pins so they fit within the confines of the board. Referring to **Figs. 3**

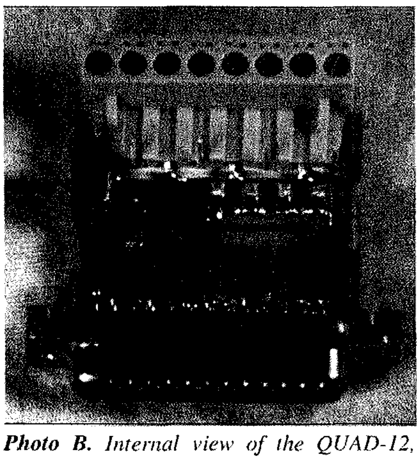

***Photo B.** Internal view of the QUAD-12, showing the surface mount soldering.*

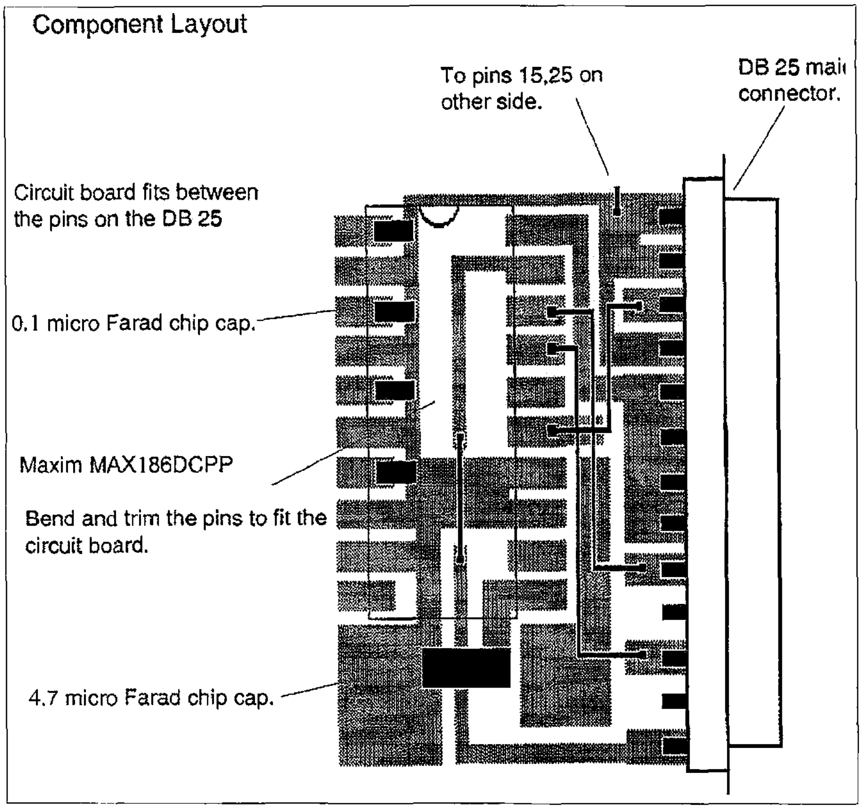

Fig. 3. Parts placement diagram.

and **4**, solder the A-D chip to the board.

Slide the circuit board between the pins of the DB-25 connector and check to be sure that the assembly fits the backshell. You may need to do some trimming. Solder the DB-25 pins to the board, filling the solder cups completely.

Solder the four connecting wires. Hold a stripped wire against the proper DB-25 solder cup and heat the cup until the wire slides into the cup. Add a little solder if necessary. Install the jumper wire under IC-1.

Using 20 gauge bus wire, connect all the ground terminals to the circuit board ground plane. The wire fits snugly in the terminal block, and no solder is required, except on the circuit board. Connect pins 25 and 15 of the DB-25 to the ground plane too.

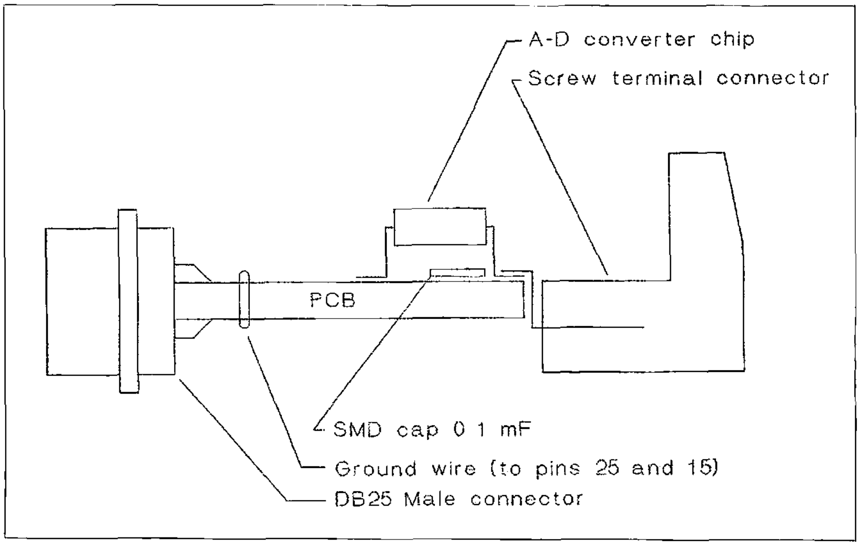

Fig. 4. Construction detail, side view.

Connect the individual input channels to the appropriate pins on the A-D chip. Refer to **Fig 1**.

After checking your work, you can give the instrument a try! Run the program listed in the sidebar, and apply a DC signal to each channel. Vary the signal amplitude from zero to 4.096 volts, and verify that an accurate conversion result appears on the screen.

If it doesn't work, change the base port address from 888 to 956. Most portable computers have the printer port at 888, but Compaq is 956. You can run a diagnostic program to find out for sure which address your computer uses (my software allows you to change the port address with a single keystroke).

With the testing complete, you can make the assembly permanent. Fill the backshell cavity with epoxy or RTV silicone. Snap the top half of the backshell in place and allow the fill material to cure overnight. The kit includes a plastic label for the terminal block. Trim it to fit in the flat the area below the terminal screws. Remove the protective backing and apply the label to the terminal block. You may need to trim any excess with a sharp knife. Once the epoxy sets, you're ready to take out your laptop and start monitoring the "outside world."

PARTS LIST

All capacitors are surface mount:

C1-C4 0.1 µF (Digi-Key # PCS6104CT)
C5 4.7 µF

Semiconductors:

IC1 (Maxim MAX186DCPP Serial A-D)

Miscellaneous:

DB-25 Male connector (Norwesco or Cinch)
DB-25 Backshell (Norwesco TT model 925M)
Circuit board (Author)
8-position terminal block (On-Shore Technology ED1707)
4 inches of 20-gauge tinned solid wire
4 inches of 22-gauge solid core hookup wire

A kit including all components and software is available for $80. The kits do *not* include epoxy or silicone. A bare circuit board is available for $3. The Datalogger software is $10, and a circuit board is included. Contact: Mike Gray N8KDD, 1680 Cooley Lake Road, Milford MI 48381; (810) 685-9248.

Vee Antenna With Vertical Tails

A multiband antenna with low-angle radiation for the low bands.

Nizar A. Mullani KØNM
719 Santa Maria
Sugar Land TX 77478
E-mail:
nmullani@heart.med.uth.tmc.edu

As we languish in the minimum in solar sunspot cycle. the major part of high-frequency communications is going to be carried out in the 30, 40, and 80 meter bands for the next couple of years. Horizontally polarized antennas for these bands have to be installed in excess of 50 feet in height to obtain the low angle of radiation necessary for DX work. Vertically polarized antennas, such as a quarter-wave ground-plane, are excellent for transmitting but poor for receiving on the low bands. Moreover, an excellent ground is required for ground-plane antennas to work well. If you are limited in the height of the antenna, then obtaining low angle radiation on the low bands becomes quite difficult.

Vee-with-tails design

A design that overcomes some of these limitations is the vee antenna modified to include vertical tails. The vee is an excellent multiband antenna in which two equal lengths of wire are formed in a vee configuration and fed with parallel-line tuned feeders at the apex of the vee. At low frequencies, the horizontal wires have to be fairly high in order to provide a low angle of radiation on the low bands.

In my design, the vee-beam antenna wire has vertical tails added at each end, reaching almost to the ground. These two vertical radiators behave like two 180° out-of-phase verticals fed at the top with current maximums above the ground. The horizontal wires of the vee antenna provide medium range reception, while the vertical tails provide the low angle of radiation necessary for DX. At high frequencies, the vee horizontal wires provide excellent gain and directivity.

Computer simulations of the vee-with-tails

Several different antenna designs with varying heights and lengths were simulated using the AO antenna simulation program. A wide range of lengths for the vee-with-tails were designed, based on the size of the lot available for placing the antenna. Some of these designs are listed in **Table 1**.

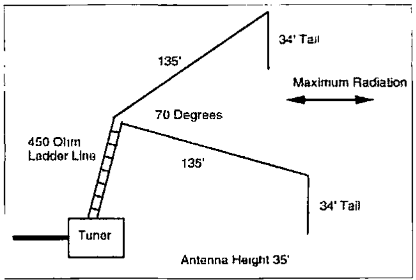

Fig. 1 The horizontal wires are 135 feet long and are formed into a vee with an included angle of 70°. Vertical tails, each 34 feet long, are added at both ends to provide the low angle of radiation from the two top-fed, out-of-phase vertical radiators. The antenna is fed with parallel wire feeders, such as 450 ohm ladder line, and matched to the transmitter with a tuner or a 9 to 1 balun. Alternatively, it can be matched with a 9 to 1 or 16 to 1 balun at the feed point and fed with coax. Different lengths and sizes of the vee-with-tails designs are shown in ***Table 1.***

The longer the horizontal wire, the more the gain at high frequencies. However, the height of the antenna becomes critical at anything over 45 feet because long vertical wires tend to radiate at high angles when their lengths become longer than one-half wavelength at the operating frequency. This basically relegates the design of the multiband vee beam with tails to antennas approximately 35 to 45 feet high. However, a design of this antenna optimized for the 80 meter band would benefit from longer vertical wires, higher antenna height, and a larger included angle between the wires. The ideal length of the vertical wires was found to be one half the wavelength at the operating frequency, though shorter lengths also work well.

Type of Antenna	Leg Length (ft.)	Vee Angle (Deg.)	Tail Length (ft.)
Author's Test Antenna	135	70	34
G5RV Vee with Tails	51	120	24 or 34
Short Vee with Tails	82	100	34
80 Meter Dipole	67	180	24

Table 1. *Some variations of the antenna designs that I've simulated on my computer. All antennas were simulated at a height of 35 feet. The length of the vertical tails can be decreased to 24 feet if necessary.*

Test antenna

I built a test antenna with 135-foot horizontal components and 34-foot vertical tails, as shown in **Fig. 1**. The total height of the antenna was 35 feet, with an included

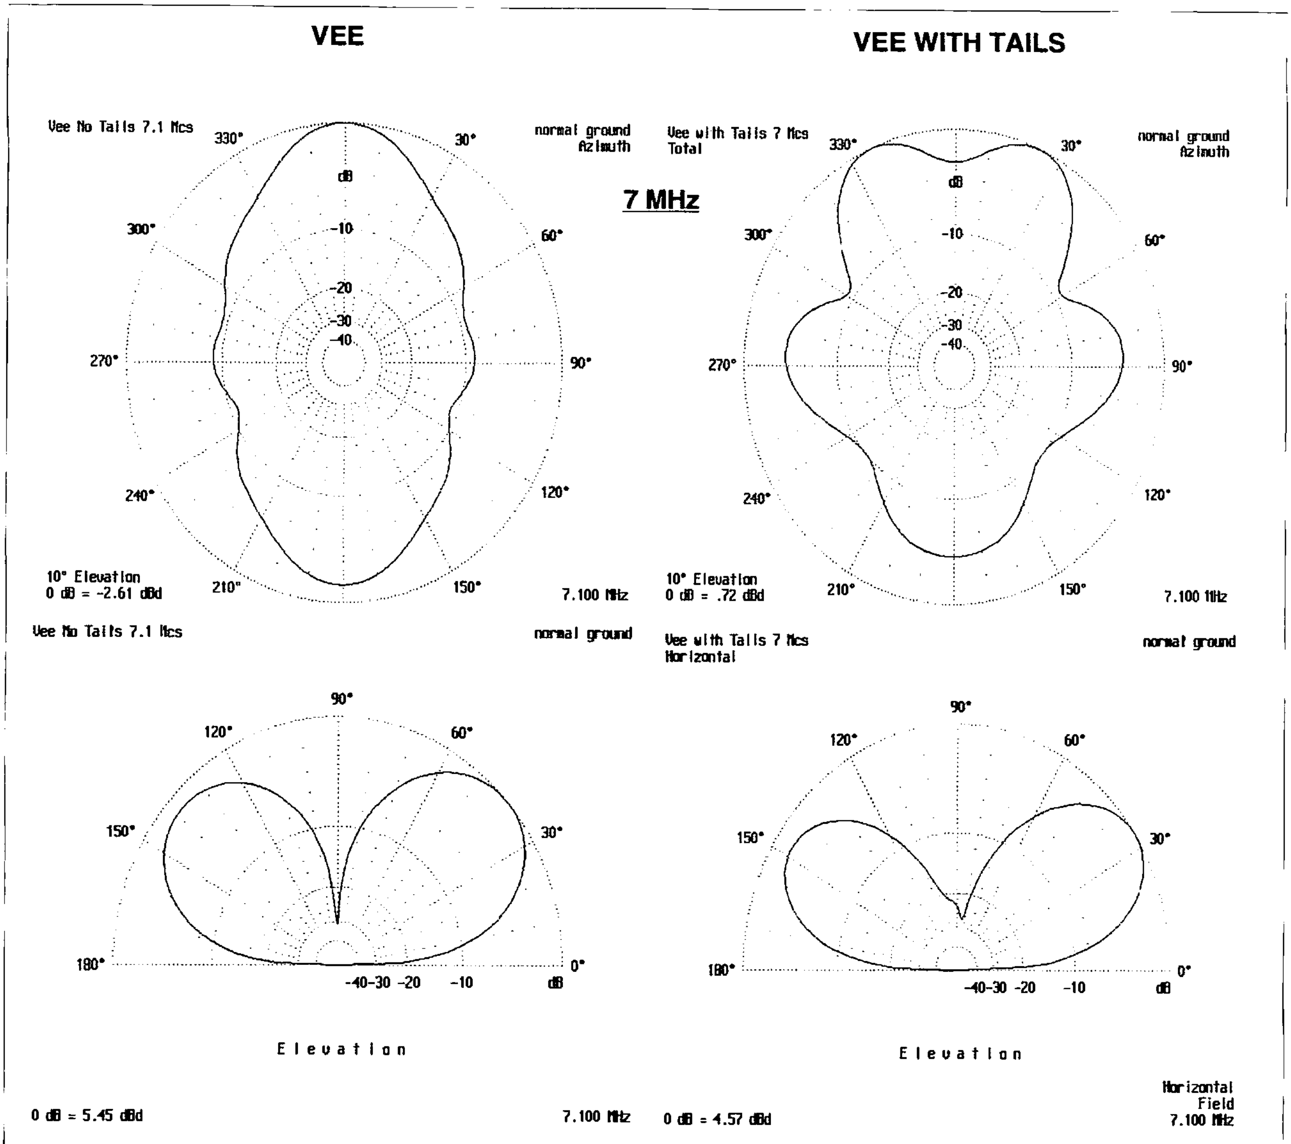

*Fig. 2. Computer generated radiation patterns for the conventional vee and the vee-with-tails for the test antenna shown in **Fig. 1**. The total field pattern is shown for an elevation angle of 10°, and the azimuth angle is chosen at the maximum point in the radiation. The angle of radiation for the vee-with-tails is approximately 10° lower than the conventional vee.*

angle of 70°. The antenna was fed with 450 ohm ladder line and a 9 to 1 balun at the transceiver. The automatic tuner in the Icom IC-738 was able to tune this antenna from 10 through 160 meters.

Final trimming of the SWR was carried out by trimming the length of each vertical wire equally. If a tuner is used between the transmitter and the 450 ohm ladder line, the length of the vee is not critical. Shorter horizontal lengths can be used, provided the included angle is made larger (see **Table 1**). Shorter vertical radiators can also be used.

"I built and tested this antenna in one afternoon with the help of my 10-year-old son."

Computer-generated radiation patterns for the test antenna

The test antenna design was optimized for the 30 meter band so it would work well from 80 to 10 meters. Computer-generated field-strength patterns comparing the horizontal vee and the vee-with-tails are shown in **Fig. 2**, for the 40 meter band. Note the broader radiation pattern of the of the vee-with-tails. The vee-with-tails has approximately a 10° lower angle of radiation due to the tails. The vertical radiation is compared to a simple ground-plane antenna in **Fig. 3,** which also shows the horizontal pattern. Note that two major lobes are formed for the vertical radiation. These combine with the horizontal radiation to provide a wide angle of coverage in the direction of the vee on 40 meters.

At high frequencies, the vertical wires radiate at high angles; however,

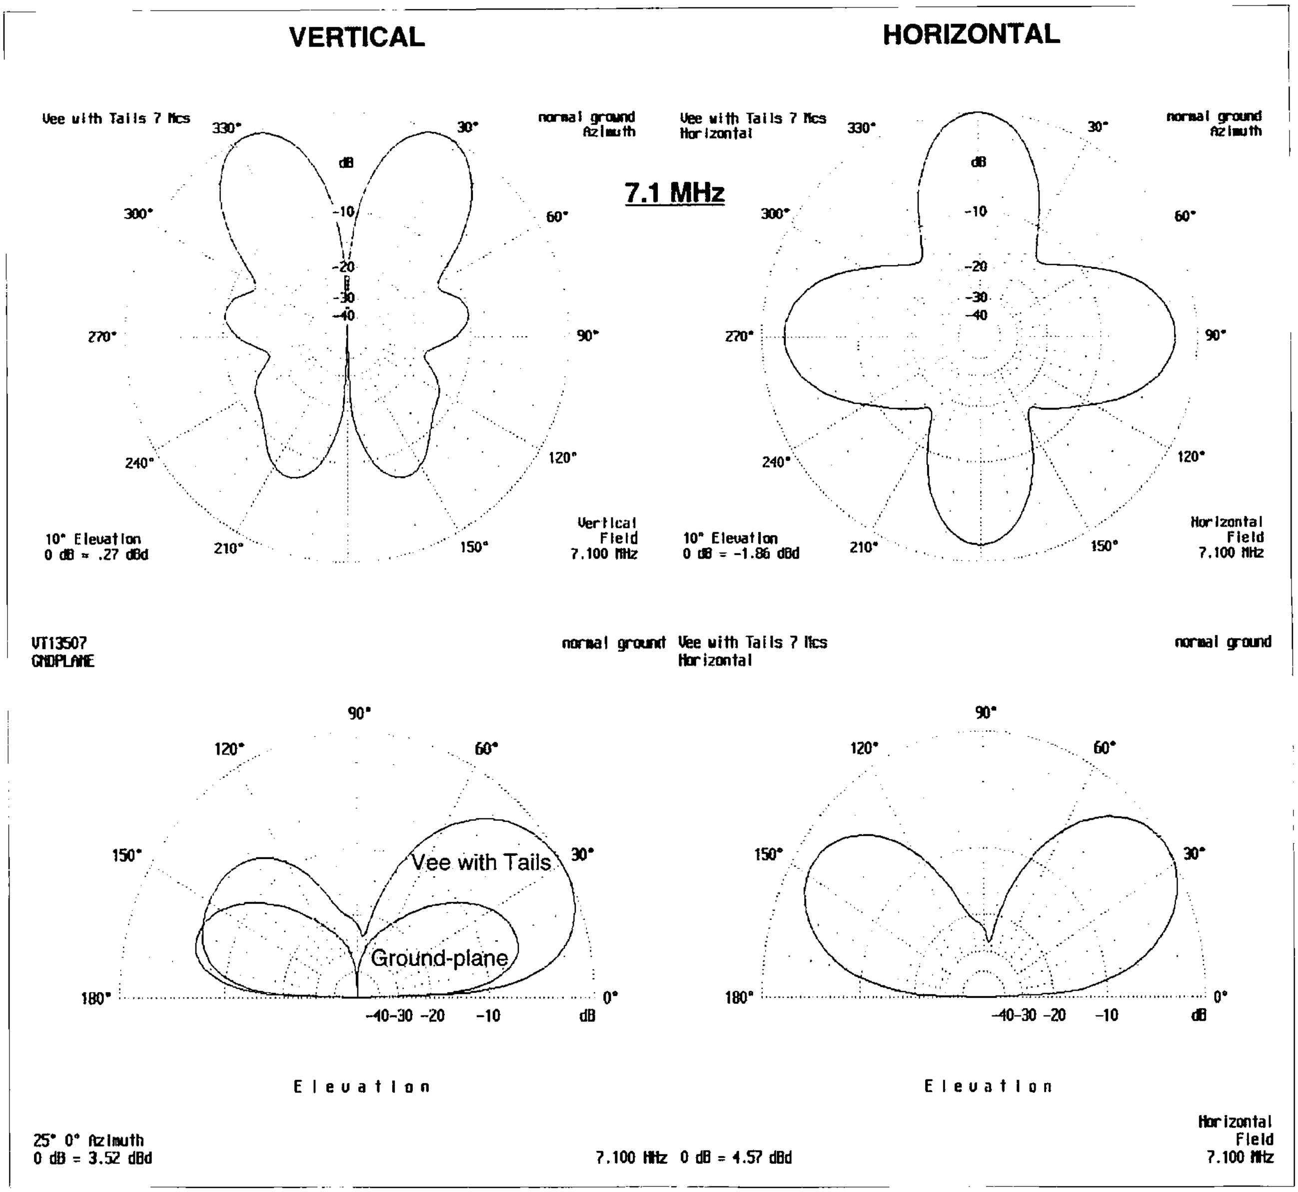

Fig. 3. A comparison of the vertical and horizontal polarization pattern for the vee-with-tails test antenna on 40 meters. The vertically polarized radiation pattern has two lobes and the major field strength is stronger than the ground-plane radiation in the direction of the vee. The ground-plane radiation pattern is superimposed on the vertical elevation graph.

the horizontal vee provides a fair amount of gain to compensate for the loss from the vertical radiators.

Fig. 4 shows the computer-generated radiation patterns for the 20, 15, and 10 meter bands. The patterns are equivalent to a three-element beam at low heights. And, even though the 17 and 24 meter data are not shown, the antenna works quite well on these bands too.

On 80 meters, the radiation pattern is dominated by the low height of the horizontal wires, which puts most of the radiation at a high angle. However, even at this low height, some low angle of radiation takes place on 80 meters, as shown in **Fig. 5**. Note, however, that the maximum radiation pattern for the vertical components in the 80 meter band is at right angles to the direction of the vee. At this frequency, the two out-of-phase vertical radiators are separated by approximately one-half wavelength and the maximum radiation pattern is in line with the two vertical elements.

"I've had a lot of fun with this antenna, especially since it is concealed among my trees and the neighbors don't even know that it exists."

Test results for the vee-with-tails

The test antenna has been used for two winters and in several contests. It was tested against a quarter-wave trap vertical antenna with ground radials as a standard. In the optimum direction of

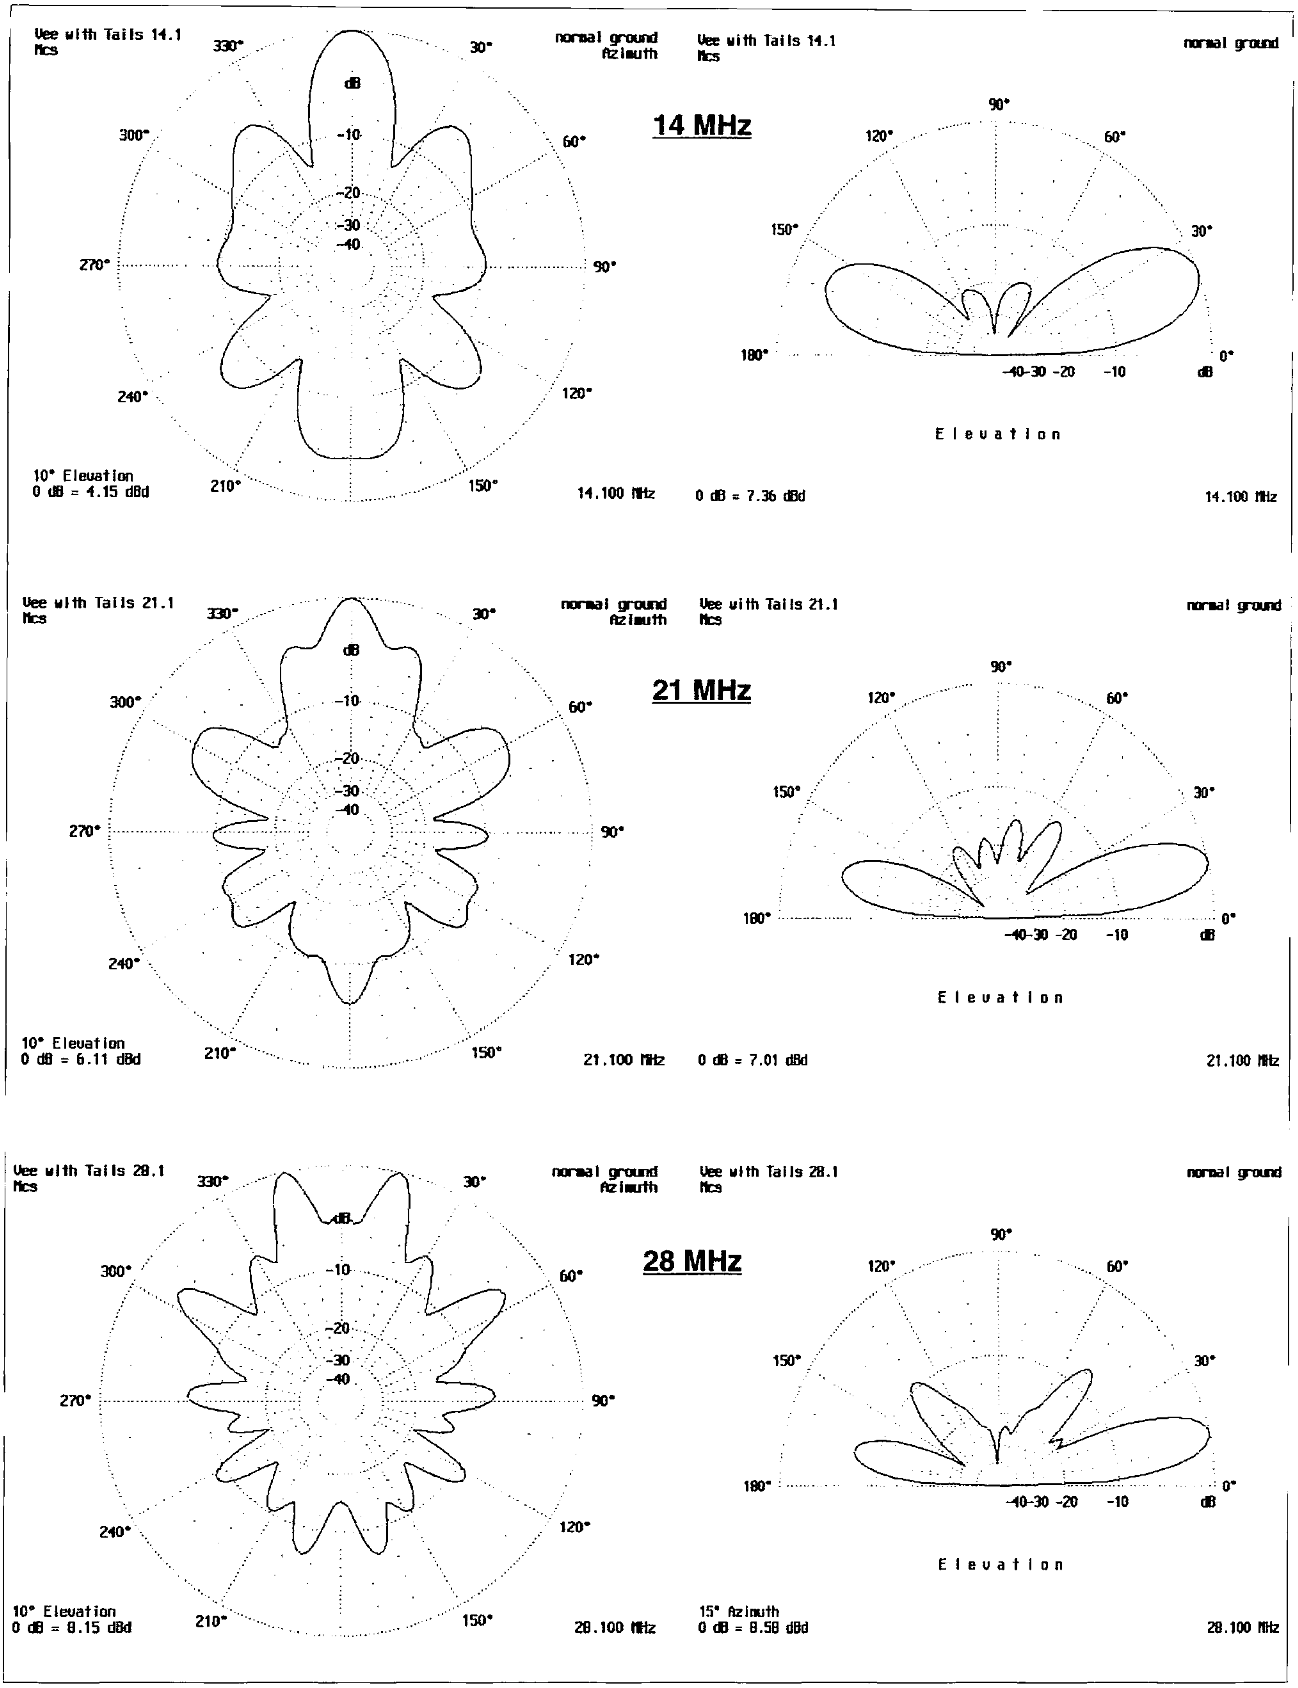

Fig. 4. Computed field strength patterns for the antenna on the 20, 15, and 10 meter bands. These radiation patterns are very similar to a vee without tails, except that the gain is slightly lower for the vee-with-tails due to some high angle radiation at these frequencies from the vertical radiators.

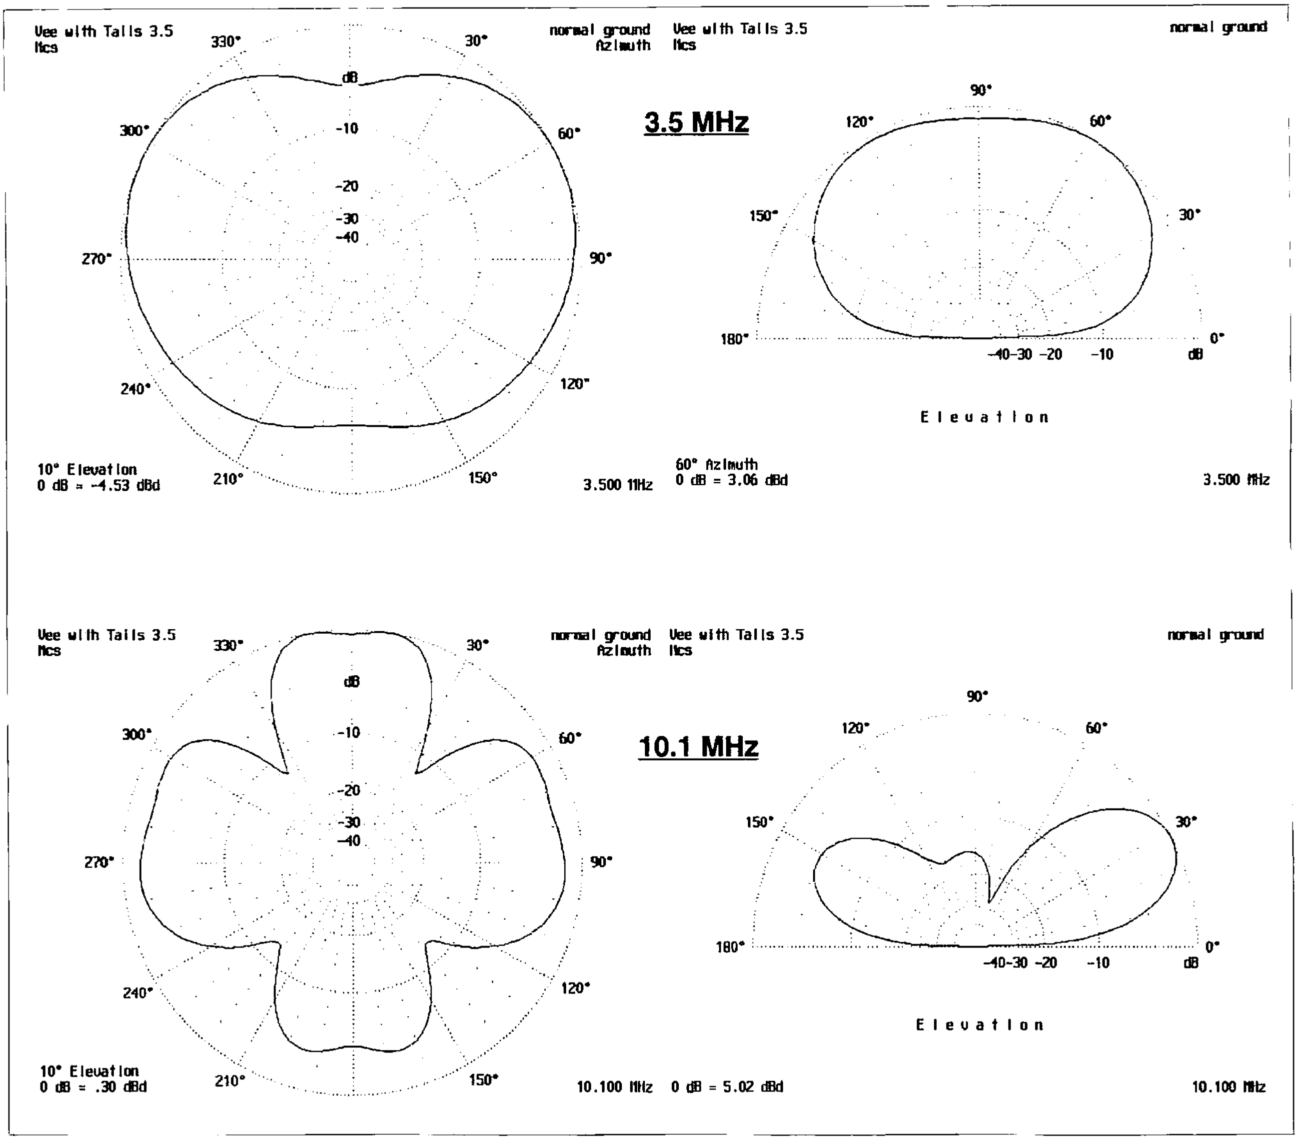

Fig. 5. Computed field strength patterns for the antenna on the 80 and 30 meter bands. Note that the maximum radiation on 80 meters occurs at 90° to the direction of the vee.

the vee antenna, which is north-northeast from Houston, Texas, this antenna consistently outperformed the vertical by two or more S-units on 40 meters. Received signal strengths at the other stations were also compared for the vertical and the vee beam with tails. Again, in the direction of the vee, the beam with tails performed two or more S-units better. Fading was reported to be much less, both for the received and transmitted signals, partly because of the mixed horizontal and vertical polarization of the antenna. QRP operation with 2 watts on 40 meters was a snap into the northeast United States and Mexico, with 579 signals. Signal strengths at 90° to the orientation of the vee were better for the ground-plane antenna than for the vee-with-tails.

Working contests was also quite easy with this multiband design. I worked most of the European and North American stations that I heard. On 20 meters, the antenna could not compare to the big yagi antennas on tall towers. However, it consistently put out a very strong signal into the northeast and Europe, comparable to a triband-type yagi antenna at a low height. During a couple of contests, when the 15m band was open to Europe, the antenna put out a very strong signal. On 80m the maximum vertical radiation is 90° from the direction of the vee. South American contacts were 579 with 100 watts, while short-skips to the US provided strong signals. I even loaded up the antenna on 160 meters during the last contest and worked 25 states in a couple of hours.

Conclusions

Considering that this antenna is designed for multiband operation and is only 35 feet off the ground, it works remarkably well. The antenna is easy to build and the tails can be adjusted for the best compromise in SWR across the bands. I built and tested this antenna in one afternoon with the help of my 10-year-old son, Ethan. The 9 to 1 balun can be replaced with an antenna tuner if desired. It is also possible to place a 16 to 1 ratio balun at the feed point and run 50

ohm coax to the tuner. A 16 to 1 balun provides a better match overall if the 450 ohm ladder line is not used.

The only critical parameter in the antenna design is the angle of the vee; that's what determines the radiation pattern at different frequencies. The shorter the horizontal length of the antenna, the greater the included angle in the vee should be. As an example, the G5RV version of the vee beam with tails has 51-foot horizontal wires with 34-foot vertical wires, and an included angle of 120°. This design works quite well on 40 and 80 meters and provides some low-angle of radiation that is not available from a conventional G5RV oriented in the horizontal direction.

The vee is very simple to construct if you have some trees in your back yard. There are several variations of the lengths and angles for this antenna which can accommodate different sized lots. The critical thing in the construction is to keep the two sides of the vee the same length. And, since wire antennas are more susceptible to damage, record the SWRs on all the bands for future reference. This way, if you suspect some damage you can easily check it with an SWR measurement.

I've had a lot of fun with this antenna, especially since it is concealed among my trees and the neighbors don't even know that it exists.

Data Acquisition

The science of data acquisition is a subject in itself, but we can cover the basics in a few words. In digital data acquisition, you need to be most aware of what **NOT** to do.

1. *Don't damage your instrument.* Never apply a voltage greater than the A-D chip can resolve. In this case 4.096 VDC. The chip can actually handle greater voltages, but it's always a good practice to stay within design limits.
2. *Don't forget the Nyquist theorem.* Set the sample interval to least twice the highest frequency you expect to see. If you don't, you may be sampling only peaks or valleys.
3. *Don't lose data.* Write data only to a RAM disk or hard drive. Floppy drives are slow and you may miss a record or ruin your time base during disk writes. Floppy drives should be fast enough for sample intervals greater than 3 seconds.
4. *Don't let unused input pins float.* Connect unused channels to ground. Generally speaking, high input impedance is a good thing because the measurement system doesn't load the system under test. An open channel is measuring the electrical potential of the air, with respect to the ground plane of the computer. It's possible for high voltage on an open channel to affect an adjacent in-use channel.

PC-Controlling Your Rig

All it takes is a few parts and a BASIC program.

L. VanProoyen K8KWD
8330 Myers Lake NE
Rockford MI 49341

I suspect there are a lot of Kenwood TS-50 owners who, like me, use this radio at home as much as they do in their cars. For its size, the radio packs in a lot of features, but one is missing: a way to enter frequency directly from a PC.

Like many current rigs, the TS-50 includes provisions for connecting a computer for direct frequency entry capability, but I didn't like their approach because it requires an outboard box with a cable coming out through the bottom of the radio. That's not my idea of something portable. The ideal would be to use a portable computer and a cable that easily connects to the rig, with no other baggage necessary. I accomplished this using a notebook computer with an easily built in-line interface and a simple control program.

Tying into the radio

After studying the TS-50's schematic, I could see that it was essentially computer-ready. The microprocessor used in the '50 is one of the newer breed of microcontrollers that include a UART (Universal Asynchronous Receiver-Transmitter) built in. **Fig. 1** is a partial diagram showing the TS-50's computer interface circuit details. In implementing computer control for this radio it looked as if I'd have to add some buffering, level conversion, and signal inversion, and come up with some scheme so that I could connect to "CN6," as shown in **Fig. 1**. CN6 is the serial data interface connector, and supplies TX and RX data, handshaking, and a 5-volt power source.

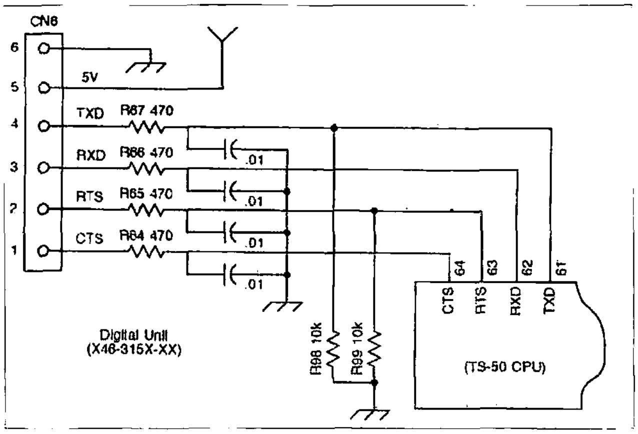

Fig. 1. Partial diagram showing the control computer interface circuits.

The rear panel of the TS-50 didn't leave room to add a new connector, but I noticed that the heat sink was tapered at the top rear on either side, leaving enough room to sneak a 1/8-inch cable out the back. This would let me hook up some type of in-line connector with which I could connect my computer. **Photo A** shows the 1/8-inch, three-circuit mini-phone type connector I used.

Photo A Rear panel view showing the added computer interface cable and connector.

I had easily passed the cable out of the radio, but I still had to make a connection at CN6 on the radio's microprocessor board. CN6 appears to be what I call a "mini-header connector," and finding anything that would mate with it in my neighborhood proved impossible. If you can find a mating connector, I would recommend using it—I decided to go without a connector. **Photo B** shows the technique I used to connect to CN6.

At first, I considered soldering wires directly to the circuit board points at CN6 (this is an option), but, in keeping with my preference to make no mechanical modifications (and possibly void any warranty), I elected to take a somewhat unorthodox approach. I selected three lengths of #22 stranded hookup wire that were long enough to run from CN6 to the rear of the radio. I then cut the CN6 ends of the wire square and carefully bored holes into the ends of each wire using a straight pin (see **Fig. 2**). The wires were then pushed over the appropriate pins of CN6, as shown in **Photo B**.

To complete the installation, I cut a small rectangle of electrical tape and carefully stuffed it between my wires and the inside of the connector's plastic shell, sticky side out (using a small screwdriver). This tape wedge provides a slight amount of "spring tension" to push the wires against the CN6 pins for good electrical contact, and it acts as an adhesive to hold the wires into CN6. Should I ever want to de-install this "modification," I'll simply pull the wires and tape out of the radio, leaving no traces of any work I've done.

I routed the wires through a small chassis opening adjacent to CN6, to the outside along the right side of the radio, and finally out the rear near the top right of the radio. To protect the wires, I ran them inside a piece of 1/8-inch diameter plastic tubing for added insulation. This is not essential, but it's a good idea to use electrical tape or something at potential "pinch-points." Outside the radio, I terminated the wires with a 1/8-inch diameter three-circuit female in-line mini-phone jack, wired per **Fig. 3**.

Check carefully to make sure there are no straggling wire strands anywhere, especially down inside CN6, since it also carries +5 VDC and ground. I used a magnifying glass and made ohmmeter checks to make sure I didn't have any problems. Also make sure the cable is tied off properly to prevent strain from being transferred to CN6.

The level converter interface

I decided to do a three-wire RS-232 implementation, even though the TS-50 supports hardware handshaking via RTS and CTS at CN6. The main reason was so I could use that small, unobtrusive connector outside the radio. Also, it kept the interface simpler, and I wanted an "in-line" device. **Fig. 3** is a diagram of the level converter interface design I developed for the TS-50, together with interconnecting wiring details. **Photo C** shows how I built it as an in-line device, part of the interconnecting cable between my computer and the TS-50.

Having done a similar interface to another type radio, I was a bit concerned about the lines from CN6 in this radio because they run directly to the radio's microprocessor—no buffers or the like (see **Fig. 1**). Any static discharge or improper voltage that came in on my cable

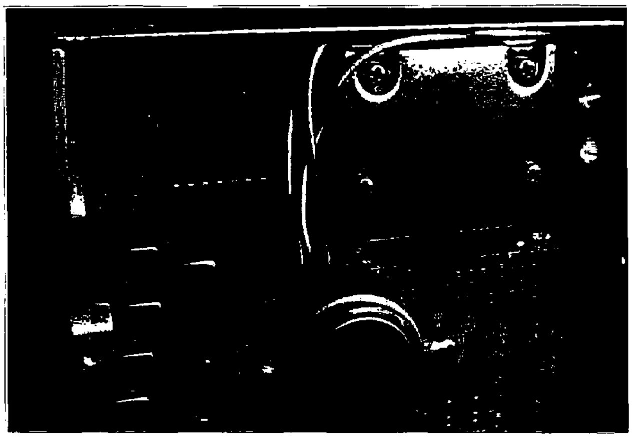

Photo B. Direct connection technique used with "CN6" on the microprocessor board (see text).

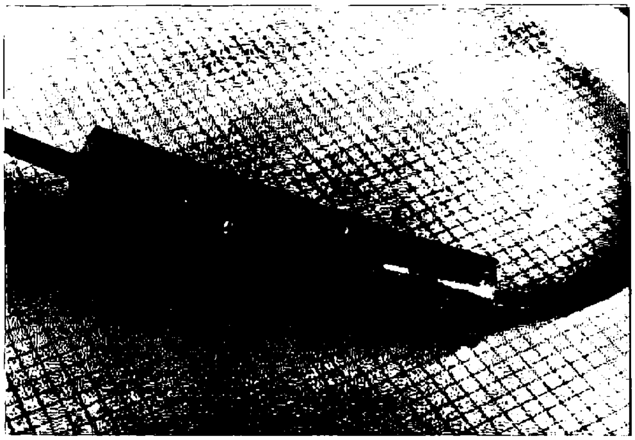

Photo C. Construction details of the RS-232 interface cable.

could do serious damage. To make this installation a little less static-sensitive, I decided to add a 10k pull-down resistor to the RxD line, similar to the one on TxD. I installed this resistor inside the shell of the mini-phone jack from the radio, as shown in **Fig. 3**. Too bad they didn't include a pull-up resistor at RxD inside the radio; it would have made my level converter design easier.

Even though +5V is available from the CN6 connector, I decided to get operating power from the computer via the DTR line. I did this to minimize the number of wires needed from the radio. Since the DTR line from my computer sits at some negative voltage level when not active, I used a diode to prevent reverse polarity powering of the interface during these periods. A second diode is similarly used in the computer's TxD line to keep the logic "positive going."

My computer's RS-232 levels (I use a Compaq™ notebook for my radio applications) vary between ±10 volts, so I designed the interface around a +10 volt supply. To assure proper operation should I want to use the interface with some other computer with higher levels (RS-232 levels can be as high as 25V), I added a 10-volt zener diode. Since my computer is battery operated a lot of the time, its RS-232 levels often drop to 7V or so as the battery discharges, but this doesn't seem to affect the operation of the interface.

The level conversion technique used in this circuit is essentially a couple of open collector switched resistance voltage dividers as pull-ups for the radio and computer RxD lines, with a few extra components added to insure adequate protection for the radio. I used 2N2222 type transistors for my interface, but any similar device would work. Since the TS-50's data rate is fixed at 4800 baud, a device with good switching characteristics should be used for satisfactory operation at this moderately high rate.

I used the maximum value pull-up resistor value (15k) that would work reliably for the computer RxD line's circuit to minimize current drain. Since I added a 10k pull-down resistor to the radio's RxD line, I needed a circuit that wouldn't exceed the TTL limit of 5 volts in the event my added pull-down resistor failed, yet would still give a reasonable TTL high level with it in. As a precaution I added a zener diode to clamp this level to a maximum of 5.1 volts. My TS-50 seems to operate fine with RxD levels as low as 2.5 volts (remember my battery) with this interface, and the zener reassures me that I won't hurt my radio.

TxD from the radio is coupled to the switch transistor base using a 27k isolation resistor, and it is

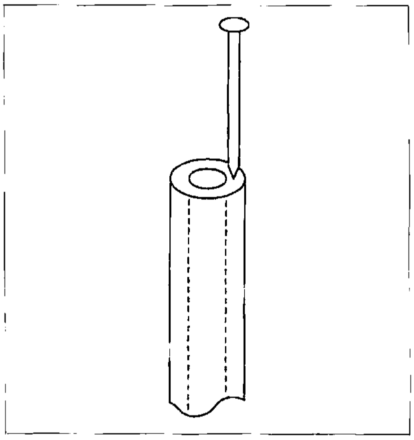

Fig. 2. Boring the end of a piece of hookup wire with a straight pin to allow connecting to CN6.

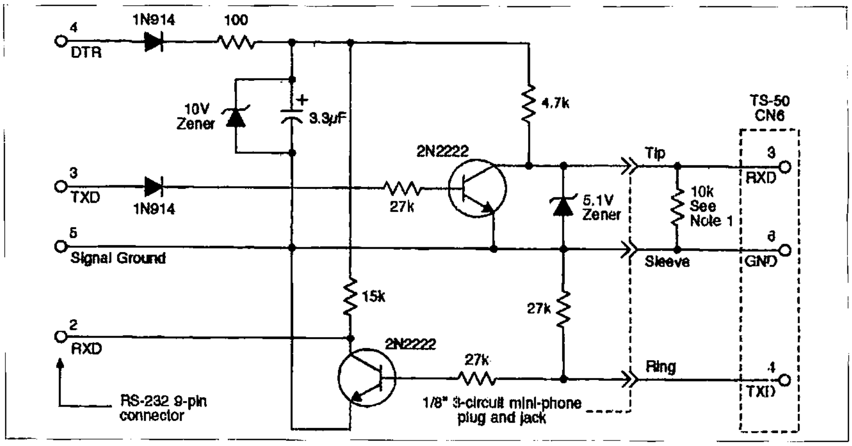

Fig. 3. The RS-232 level converter circuit and interconnect wiring details. Notes: 1) 10k resistor installed inside mini-phone jack cell. 2) All resistors 1/4 watt.

loaded by a second 27k to signal ground. In a like fashion, the computer TxD is also coupled through another 27k resistor and a diode to prevent reverse bias of the switch transistor.

Construction

The level converter interface circuit is built on a 1/2-inch by 1-1/4-inch piece of perf board to fit inside a 1/2-inch diameter piece of plastic tubing, as shown in **Photo C**. The component layout is not critical, other than placing them on the board in a low profile manner such that the whole assembly will fit inside the tube.

The tubing serves as an enclosure for the interface and as a strain relief for the cables. I secured the cables to the tubing with tie-wraps inserted through slits I cut into the tubing.

The circuit wiring is point-to-point, with jumper wires connecting the points as required. I used Teflon™ wire because it was available, but any good hookup wire will work. I attached the interconnecting cables by directly soldering the individual wires to their connect points at the perf board.

Because of the potential to emit RF noise, some special attention should be paid to RS-232 cables. I used shielded wire for both the computer cable and the cable to the radio. The computer cable is a four-conductor shielded type, and I connected the shield to one of the wires at the computer connector end only, letting the shield float at the interface board end. Similarly, the radio link cable has its shield connected to a wire at the plug end only. I did not use shielded wire inside the radio because the majority of it is run between the radio chassis and cabinet. Also, I used the ground connection at CN6 only, as a single-point ground at the radio to avoid any possible "ground-loop" problems.

Preliminary checkout

I would suggest making a few continuity and resistance checks to verify your wiring before plugging the interface in. Once you're satisfied everything is wired correctly, preliminary tests can be made by connecting the interface cable assembly to your computer's COM port and bringing up a communications program. I used the terminal program bundled with Windows©,

CIRCLE 276 ON READER SERVICE CARD

configured for 4800 baud, eight data bits, no parity, two stop bits, and software flow control.

With the communications program properly configured and the interface cable plugged into the computer, you should measure +3 to 5 volts between the radio plug sleeve and ring, and zero volts between the sleeve and tip. If you then short the tip to the ring, and hit a few keys on the keyboard, you should see these characters echoed on the computer screen, indicating the interface is functional.

Once the interface is verified as functional, you can connect it to the radio. I recommend connecting and disconnecting with power off at both the computer and radio, but I have hot-connected the interface with no harm. Once connected, and with the communications program configured as previously described, try typing "IF;" (use uppercase letters and don't use the quotation marks). The radio should reply with a string of data similar to that shown in **Table 1**. If this works, you have verified that the interface is working and capable of sending and receiving data to and from the radio.

Control software

Kenwood Radios are perhaps the easiest to write control software for because command and data formats are in ASCII text format. This means you can use a standard terminal program, such as that bundled with Windows, to send commands and display data, although a custom program to enter and display data in a more user-friendly format is much nicer to use. The TS-50 uses a subset of commands that many Kenwood radios use, and I have included those I am aware of in **Table 1**. For those who wish to experiment in writing their own custom control program, I have included a QBasic listing of a program for entering and displaying frequencies in the sidebar, as an example of how easy such programs can be.

Direct Frequency Entry & Display Program for the TS-50

TS-50TST.BAS

Sample QBasic Frequency Write and Display Program for the Kenwood TS-50. (This program was tested on the TS-50 using a Compaq Aero Notebook Computer 11-30-95.)

```

Table 1. Miscellaneous TS-50 Commands and Data Formats

Command	Data Format
General Format	All commands are in upper case letters and are terminated with a semicolon (;). Many commands are dual function—they can be used to read and to write data.
FA;	Returns current VFO A Frequency as: FA00003976000; for example. The frequency data is in an eleven digit format with the left most digit representing the 10 GHz value, and the right, the 1 Hz value. This example translates to a frequency of 3.976 MHz.
FA{data};	Writes a frequency to VFO A. Note that there are 11 data digits that must be filled (using zeroes as appropriate) for this command to work. It's possible with the TS-50 (and I suspect other Kenwoods) to write frequencies to 1 Hz resolution.
FB: and FB{data};	Same as FA; and FA{data}; as described above except these commands read or write frequency to VFO B.
FN{Cmd Code};	Function command, sets VFO A/B or Memory: FNØ; = VFO A FN1; = VFO B FN2; = Memory Mode
ID;	Returns Radio Identification Number: IDØ13; (for the TS-50)
MD{Cmd Code};	Mode Command, sets Communications Mode: MD1; = LSB MD2; = USB MD3; = CW MD4; = FM MD5; = AM MD6; = FSK
RX;	Commands Radio to receive (see TX command).
SP{Cmd Code};	Sets Split Mode on or off: SPØ; = OFF SP1; = ON
TX;	Switches Radio to transmit. Once sent, the radio remains in transit until the RX; command is sent (or power off).
IF;	Returns current status in a 35 character string such as: `IF00001850000      -015000 0701000     ;` where the first eleven characters represent frequency in the same format as 'FA' above. Characters 12 thru 16 are not used. Characters 18 thru 21 represent RIT frequency in Hz, with the 17th giving the direction as plus (+) or minus (-). Characters 22 and 23 indicate RIT/XIT status respectively; a zero = off, a one = on. Character 24 is not used. Characters 25 and 26 indicate Memory Channel number. Character 27 indicates whether the rig is in receive or transmit; zero = receive, one = trânsmit. Character 28 indicates current mode (see mode command above). Character 29 indicates function similar to function command described above. Character 30 indicates whether scan is on or off; zero = off; one = on. Character 31 indicates if split mode is on or off; again, zero = off, one = on. Characters 32 thru 35 are undefined.

Worthy of Recognition: Hap Holly KC9RP

Blindness is a challenge for this versatile, accomplished ham.

Dave Miller NZ9E
7462 Lawler Ave.
Niles IL 60714-3108

In the March 1996 issue of *73*, Wayne Green asked readers to consider generating some articles on fellow hams who they felt deserved acknowledgment before they became Silent Keys and were recorded only in memory. It's easy to recount an individual's achievements after he or she is gone, but if someone is doing something worthwhile, don't those deeds deserve recognition while the person is still around? I think so, too.

When Uncle Wayne wrote about it in his editorial, I immediately thought of a friend of mine, someone who's overcome a great obstacle to become recognized as doing something worthwhile each and every week for the amateur radio community; Hap Holly KC9RP, founder, guiding light, and moderator of the weekly amateur radio audio feature magazine known as RAIN—the Radio Amateur Information Network.

RAIN

From his home studio/ham shack in suburban Chicago, Hap produces his 12 to 17 minute weekly amateur radio program service, featuring timely interviews, thought-provoking commentaries from other hams (yours truly included), excerpts from Dayton Hamvention Forums, and other items of general interest to the amateur community at large. Ham radio is traditionally an aural—as opposed to a visual—medium; we meet and recognize fellow hams primarily by voice, seldom seeing them in person. RAIN programming is also an aural medium, distributed to hundreds of repeaters across the country via the RAIN dial-up line, commercial satellite, Hap's subscription service on audio tape, and WAØRCR's weekly 160 meter informational broadcasts. Those repeater groups, and others, then replay the weekly RAIN tapes over their local repeater systems on their regular "net night" gatherings, permitting thousands of hams to hear Hap's offerings for that particular week. It's all done with volunteer help and, in the best of amateur traditions, without profit to anyone involved.

Hap Holly makes it happen; he's an uncommonly intelligent and outgoing individual. Hap is also very aurally oriented and insists on quality in every way in his RAIN programming. He conducts most of the interviews, edits and engineers all of the program material, writes the scripts, duplicates and mails out the RAIN cassettes, and archives and catalogs the RAIN library. It's all accomplished by touch and by ear. Hap is one of a number of non-sighted amateurs within our ranks, but you'd never know it.

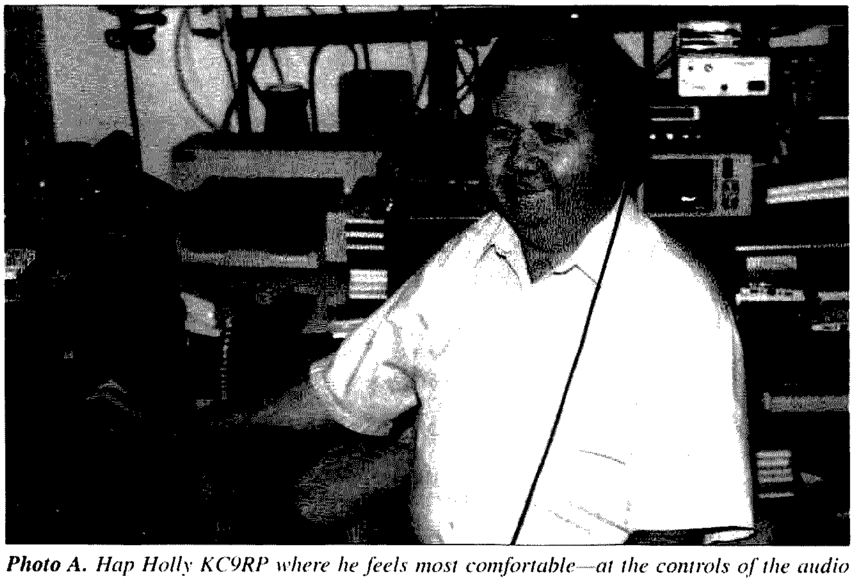

Photo A. Hap Holly KC9RP where he feels most comfortable—at the controls of the audio board, where he puts together his weekly RAIN amateur radio audio magazine show, and

Hap's history

For Hap, blindness came literally overnight when he was only seven

years old. Problems with his vision began when he was four, but then he awoke one morning totally blind. The condition is untreatable, at least within current medical terms, but to Hap, it hasn't been a handicap. In fact, in talking to him over the years, most of his friends tend to forget his unusual challenges because he does so much of what we all do, without mention of his visual impairment.

Both of Hap's parents were blind. His father's vision loss resulted from a football accident in college, but Hap's dad still became a successful building contractor and architect, formulating the plans he devised within his "mind's eye," then describing the details precisely to his secretary, who constructed balsa wood models. Then, only by touch, he would go over the "three-dimensional plans," incorporating additions or changes as needed. Hap's father was also a longtime columnist for the *Christian Science Monitor* and was known worldwide for his "Ask a Builder" column, which he wrote from 1965 until his passing in 1984. He was a touch-typist—as is Hap—and was able to generate his column by that method alone (before the days of computers, word processors and voice synthesizers).

Hap's mother lost her sight when she was around twelve years old. A 1988 book about her life, titled *What Love Sees*, depicted her struggle for independence from her New England industrialist father, her marriage to Hap's dad, and the eventual challenges that two sightless parents encountered raising four sighted children—then Hap, too, became blind. The book is being made into a made-for-TV movie this year, which will be shown on the CBS television network when completed. It will star Richard Thomas of the original "Waltons" series, and Annabeth Gish, who played Pat Nixon in the widely acclaimed motion picture "Nixon." The TV movie, which is also called "What Love Sees," primarily takes place in the small Southern California ranching town of Ramona (where much of it was filmed), and reportedly follows the Holly household up until shortly

after the time that Hap's sight was lost and the family was forced to move to a larger city—Escondido—to seek specialized educational opportunities for their youngest son. Hap was able to spend a few hours with the movie company as they were shooting the film, meeting with and talking to the actors, including the eight-year-old boy who portrays the "young" Hap Holly. Be sure to watch for "What Love Sees" this October on CBS. The original book, from which the movie's script was developed, is scheduled for reprinting this summer, in large print form from Thorndike Press, for readers with visual handicaps. Also in the works is a proposal for a "talking book" version of the original book to coincide with the publication of the large print edition.

Hap's ham career began when he earned his Novice ticket in 1965, at the age of 14, receiving the callsign WN6UJH, while living in Escondido. He became a General—dropping the "N" in his call—a year later, in 1966, and served as a phone-patch station and net control for the Westcars traffic net until 1970. Hap then headed off to Principia College in Elsah, Illinois. From 1970 until his graduation in 1974, he ran phone patches and kept radio schedules for his fellow students. He graduated with a Bachelor of Arts degree in sociology, and soon found himself in the Chicago area, where he sought out world-class jazz accordionist Leon Sash, to pursue his other love, music. A year later, another love, Stephanie, became the center of Hap's attention and the two were married in August of 1976. They had met the previous summer at the Roundup Ranch in Buena Vista, Colorado, where Hap was a counselor. He taught a class in non-visual perception to the high school campers at the ranch, all of whom were sighted, but who learned to "see" in yet another way, with Hap's patient guidance. Hap's wife, Stephanie—who is sighted—received her ham ticket and the call KA9WKD in 1986 after realizing how much ham radio, and the good it was able to accomplish, meant to Hap.

In 1977, Hap picked up the "9-land" call of WD9GJQ when he and Stephanie moved into their comfortable home in Des Plaines, Illinois, where he resumed his phone-patching and DXing activities with his now permanent antenna and station setup. In 1981, Hap passed his Advanced Class license exam and changed calls once more, this time to his current KC9RP callsign.

I met Hap when he served as ham radio informational programming guru for the BEAR, the Broadcast Employees Amateur Repeater in suburban Chicago, from 1984 to 1989. Hap's weekly "net nights" became something of a legend in the Chicago area, sometimes attracting in excess of 100 check-ins, via simulcasts on five area repeaters. This stint led to Hap's forming RAIN and the weekly RAIN Dial-up, the RAIN Monthly audio tape and the bimonthly RAIN Journal tape (produced especially for blind amateurs). According to Hap, "My inspiration for producing weekly ham radio programming resulted from my need to know. I faithfully listened to the weekly Newsline (formerly WestLink Radio) reports in the early 1980s on my local repeater. I owe a great deal of gratitude to Newsline's founder and producer, Bill Pasternak WA6ITF, for his encouragement and direction. RAIN is truly an offspring of Newsline, but with a human interest focus, as opposed to a news-only approach."

As mentioned before, Hap's RAIN programming can now be heard on hundreds of ham repeaters across the nation, or by calling 847-827-RAIN*. Vern Jackson WAØRCR also carries the RAIN Dial-up on his 160 meter Gateway Radio Newsletter AM bulletin service from Wentzville, Missouri, on 1.860 MHz several times each week.

In recent years, Hap has written for *Spec-Com Journal, Radio Scan Magazine*, and, occasionally, reports for Newsline. He's a common sight at the yearly Dayton Hamvention, taping a number of the forums with the help and cooperation of the Hamvention organizers. Excerpts of these forums are then incorporated throughout the year in Hap's RAIN programming, making Dayton come alive for those of us who may not have been able to attend personally.

Hap is also active on HF, VHF, amateur radio packet, and now the Internet, using his Versa-Braille II Plus terminal. The Versa-Braille allows an accomplished Braille reader like Hap to "read" the packet bulletins and to access his Internet E-mail with nearly the speed of a sighted user. He's also working with his 386 computer and a standard keyboard, in conjunction with a speech-output device.

As a professional keyboardist, Hap's diverse repertoire of music from the last 60 years has made him a popular choice for Chicago area musical engagements. He's also an active and honored member of the Des Plaines Lions Club and received their prestigious international Melvin Jones Fellowship plaque for his service to humanity. As a member of the Des Plaines Toastmasters, Hap has served as its president several times, and has twice served as an area governor.

For Hap Holly, blindness has never been a disability, only a challenge that has served to "fine-tune" his other senses. If you have a friend or relative with a serious handicap or disability, and you've felt that amateur radio would be a worthwhile hobby for them to pursue, perhaps Hap's extraordinary story might be just the inspiration they would need to take the plunge. Hap would disagree with my choice of terms (extraordinary) since he considers his accomplishments no more than the expected effort required to achieve anything worthwhile—but then that's the signature of extraordinary people, isn't it?

Hap's RAIN Dialup can be accessed by calling 1-847-827-RAIN (7246). Hap's Internet E-mail address is hholly@ais.net. His amateur packet address is KC9RP W9ZMR.EN52VA.IL.USA.NOAM. RAIN's mailing address is RAIN, P.O. Box 2565, Des Plaines IL 60017-2565. Hap can receive voice-mail at 1-847-518-6551

NEVER SAY DIE
Continued from page 4

not many attendees ventured. Several hams with "Staff" hats on came by my booth, but none said anything about it being nice that we were there. None offered any help. There was no area set aside for exhibitors to rest or get a cup of coffee. We all had to either queue up to the single commercial food supplier and buy our lunch or go hungry. I looked at the long line a few times and went hungry. Not that the menu or the high prices were attractive.

I did enjoy talking with old friends and we sold a handful of subscriptions.

Dayton is successful because they have an experienced team running it. The Atlanta HamFestival did not pursue me to talk far enough ahead for me to alert the *73* readers who enjoy my talks and get them to come. That can usually bring in a few hundred loyal fans.

Some of the hams I talked with had also attended Dayton a few weeks earlier. Now, if Dayton can bring 'em in from Georgia, obviously a well-run and promoted show in Atlanta should be able to haul 'em in from Dayton. And should be attracting ham caravans from Missouri, Arkansas, Louisiana, and so on.

These days, with the hobby in a near zero-growth mode except for Techs, hamfests need showmanship to attract attendees. Hamfests are in serious need of some new ideas and sizzle.

Adventure Anyone?

Are you getting your share of adventure out of amateur radio?

The greatest adventures of my life have come from ham radio, so in my radio interviews and hamfest talks I point out the adventures the hobby makes possible. Whether you take advantage of the opportunities for adventure or not is up to you. They're there, if you watch for them, and your ham ticket is the key to open the door to adventure.

My ticket got me into the Navy during WWII as an electronic technician. I was originally slated to work in a research lab in Anacostia, Virginia, right across from Washington, DC. Instead, I volunteered for duty on a submarine and as a result had a couple of lifetimes-worth of adventure. I've written about all that in my $8 book on the subject. We had quite a few ver-r-ry tense moments. It sure was exciting at times.

Hey, how come you've never gone on a DXpedition? Ask anybody who's gone on one and they'll tell you that you'll remember every minute of it for the rest of your life. My first DXpedition was to Navassa (KC4AF), a tiny island down between Jamaica and Haiti. Wow, what a fantastic trip that was! Yes, we came tha-a-t close to being killed a couple times...but we weren't.

Then there was the time I heard about an around-the-world flight with a 20m ham station aboard that needed an extra operator. Operation World Wide, it was called. That's right, an all-expenses paid trip around the world, working 20m all the way around! Yes, of course I volunteered.

Or how about the time Robbie 5Z4ERR on 20m talked me into visiting Nairobi? Well, I'd just read a book by Herter on how to go on an African Safari for $690, so I asked for some company in my editorial and got two hams to go along. And since it only cost a little more to keep on going around the world, we went hunting and then got to places like Baghdad, Khartoum, Katmandu, Damascus, Rangoon, and so on, operating wherever possible. Like from the now famous American Embassy in Tehran. And Afghanistan. Talk about adventure!

How about when the State Department selected me to

A $60 Red Hot Receiver Kit!

The Ten-Tec 1253—another winner. Fire up your soldering iron!

Mike Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

It's just about as old as radio itself. I'm talking about the regenerative receiver, which was invented by Major Armstrong. This is the receiver that got the radio hobby we have today started. Along with the "super-regenerative" receiver and then the "superhet," radio has changed very little from the rig Armstrong invented so many years ago. I've never had the time to sit down and build a tube type regenerative receiver, but I've read countless articles on their construction. So, when I spied a regenerative receiver kit made by Ten-Tec, I knew I had to have one.

The Ten-Tec 1253 is a nine-band regenerative receiver with more features than most direct conversion (and superhet) rigs many QRPers build. And there's more. For, you see, Ten-Tec also designed this kit around a really slick-looking box. It's much more radio than you might think, with a selling price of $60. You get a lot of controls to play with. There's RF gain, regeneration, main tuning, fine-tuning and the volume control (see **Photo A**).

"The result is a good looking, good sounding radio for a darned good price."

You can select any of nine popular shortwave bands by the use of pin diodes. The regulated power supply and the varactor tuning produce a smooth tuning action. The use of a "bandspread" fine-tuning control makes picking out CW signals a snap! Best of all, there's not a single coil to wind! So, with that in mind, let's look a bit closer inside the Ten-Tec 1253 shortwave receiver.

Inside the kit

There are two PC boards. One contains the audio, regeneration components and the required L/C networks for the various bands. The second board contains the band switching electronics. This small board is double-sided with plated-through holes. The main PC board is single-sided and not plated. However, there is a coating on the main PC board that acts as a solder mask. Although this coating covers every pad on the board, you can solder through it with no problems (see **Photo B**).

All the pieces parts are included for both PC boards. Ten-Tec gives you all the nuts, washers, and board-mounted components.

Assembly is straight forward. The manual starts out with several questions and answers about following the manual or jumping right into the pile of parts. I decided to follow the manual, beginning the assembly by stuffing the main PC board with the audio components. After soldering and cutting off the wire leads I had the option of testing out this part of the receiver before proceeding. I recommend you follow Ten-Tec's testing steps. After all, if the audio section doesn't work, adding more parts to the circuit board will not fix the problem in the audio stage.

I tested the audio and found it working as it should. I also noticed, as the assembly instructions continued, a note about wrapping the loose wires (used in the audio test procedure) around the volume control to prevent their breaking off. That's a nice touch.

The next step was to follow the step-by-step instructions for assembling the RF amplifier, the regenerative detector, and varactor tuning.

Again, they suggest you test the receiver to make sure the regenerative detector is working, before going to the next step, which is to decide how you want the regenerative detector to work. Adding an extra coil and capacitor to the detector controls changes how the regenerative detector behaves. Adding the extra parts increases the sensitivity to weak signals, but requires a careful hand in controlling the regeneration control. Ten-Tec recommends that newcomers to regenerative receivers *not* install the two extra parts.

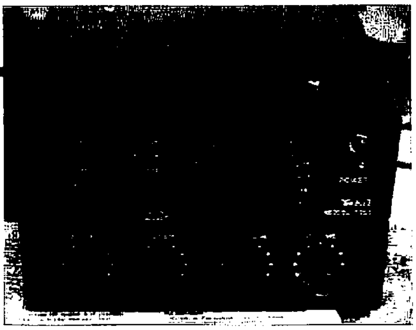

Photo A. You get a lot of controls to play with. There's RF gain, regeneration, main tuning, fine tuning and the volume control.

The next testing step has you adding the necessary parts for one band. The band selected is 6.8 to 8.5 MHz. There's always something on these frequencies, no matter what time of day or night.

I noticed two things when I applied power to the radio. First, the damn thing worked! Second, the radio sounded *really* good! There's plenty of audio from this little guy, thanks in part to the hybrid audio amplifier. With the radio operating, I tackled the band switching board, which was a bit tricky to assemble. Parts are placed on *both* sides of the board, so it's easy to get confused as to what goes where. Ten-Tec makes the assembly as painless as possible with an oversized PC board layout and a table showing you on which side each part goes.

The hardest part is aligning the nine small LEDs with the holes in the front panel, and then soldering them in place.

The mounting holes on the front panel are designed to allow some slop in your assembly of the LEDs.

After you have checked out the band switching board, you finish by stuffing the balance of the band specific components on the main PC board. This requires close attention. If you get one of the inductors or one of the wires from the band switch out of place, then the selected band may not match the LED.

The only steps left were connecting the remaining wires to the two circuit boards and installing the hardware. The receiver is assembled on a sub-chassis and then the sub-chassis is mounted inside the main box. There are two plastic battery holders to hold the eight C cells for portable use which mount above and to the rear of the sub-chassis, using a second sub-chassis.

All in all, Ten-Tec did a marvelous job of designing the 1253 kit. But naturally, like any ham, I have a suggestion: How about putting the main PC board overlay on a separate sheet of paper along with the schematic of the 1253? That would make it easier to troubleshoot without having to flip back and forth between the pages of the manual.

The manual

Aside from the single overlay sheet, a complaint I have with nearly all kits, the manual is complete and easy to understand. Ten-Tec has included points of soldering, installing parts on the PC board and detailed operating instructions. There's even a section on installing an antenna and how to tune in SSB and CW.

On the air with the Ten-Tec 1253

The 1253 takes some getting used to. When you advance the regeneration control to just below the point of oscillation, this is the best place for AM detection. Then you advance the regeneration control a hair to where the detector breaks into oscillation for CW and SSB reception. By selecting the point of regeneration, you have control of how sensitive the detector is.

It's amazing how sensitive the 1253 is! I was able to pull in AM shortwave stations from all over the world with just a 10-foot length of wire lying on the floor.

The ability to operate from the internal batteries makes the 1253 an ideal travel companion. And there's plenty of room inside to install a simple RF preamplifier. Drill a hole in the top for a telescopic antenna and you'll have a fine rig for camping. A rear-mounted headphone jack automatically disconnects the internal speaker.

In use you'll find that with a regenerative receiver strong signals have a tendency to swamp the detector, causing it to lock up on the signal. And increasing the RF gain causes it to change frequency. Although the 1253 has a stage of RF amplification, regenerative receivers do produce a signal (the output of the detector) that can radiate quite some distance.

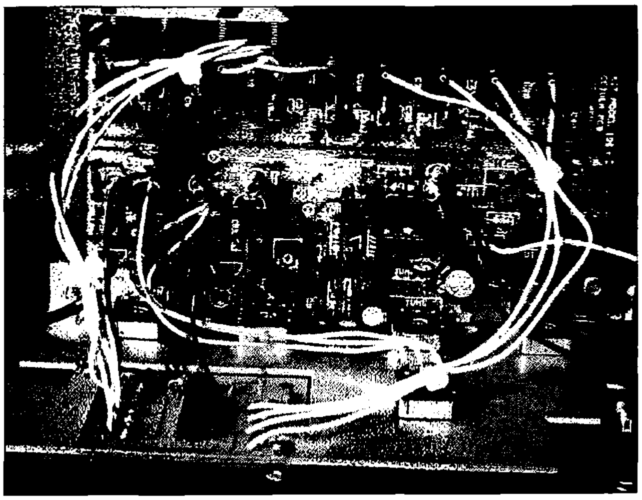

Photo B There are two PC boards. One contains the audio, regeneration components and the required L/C networks for the various bands. The second PC board contains the band switching electronics.

All in all, I had a ball with this guy. It's easy to build and easy to fix. The end result is a good looking, good sounding radio for a darned good price. I highly recommend the Ten-Tec 1253 shortwave receiver kit. Interested? Call Ten-Tec's information line at (423) 453-7172, or write them at 1185 Dolly Parton Parkway, Sevierville TN 37862-3710.

Simple Crystal Activity Tester

Check and match crystals for your home-brew projects.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30 - c/o Defendini
Salinas PR 00751-0030

Quartz crystals are found in practically every piece of electronics used by today's amateurs. Hams who build their own equipment find themselves using crystals in many projects.

Many low power transmitters and double conversion receivers require crystals for their stable oscillators. Crystal ladder filters used in receiver IF circuits must have crystals closely matched in frequency to ensure steep skirts.

Crystals are available from a variety of sources. Most hams, especially older hams, usually have spare crystals in their junk boxes. These are often available for very low prices at hamfest flea markets. Most such crystals are in the lower ham bands, while some are multiplier types for higher frequency bands.

Most mail order parts dealers advertise long lists of inexpensive surplus microprocessor crystals, ideal for ladder filters in receiver IF strips. Many, too, are suitable for use in home-brew test equipment such as capacity and inductance measuring instruments.

Regardless of its intended use, a crystal must be active. That is, it must start oscillating immediately when power is applied. It must oscillate on a single frequency, and that frequency must be stable. The more active a crystal is, the better it will perform, whether as an oscillator or in a filter.

In addition to being of good quality, the several crystals used in receiver IF filters must all be matched to the same frequency within tight tolerances. Purchasing a set of four, six, or more frequency-matched crystals from a manufacturer is extremely expensive. Buying a handful of surplus microprocessor crystals for about a dollar each and matching them yourself will cost only a fraction of the price of a commercial set.

The simple instrument described here enables easy checking of crystal activity. Used with a frequency counter, crystals can readily be matched in frequency to within a few hertz. It covers the important range of below 1 MHz to slightly above 13 MHz. The crystals used by hams in oscillators and filters fall within this range of frequencies.

Two versions of this instrument are illustrated: a simple and a deluxe. The only difference is in the method of indicating crystal activity. In the simple version, the brightness of an LED indicates activity level; in the deluxe version, a meter indicates activity level. In its simple version this instrument can be constructed in under one hour for less than five dollars, and probably at no cost at all when using junk box parts. The deluxe version will cost little more.

Circuit description

Fig. 1 shows the schematic version for the simple version; **Fig. 2** illustrates the changes required for the deluxe version. Please refer to this illustration for the following discussion.

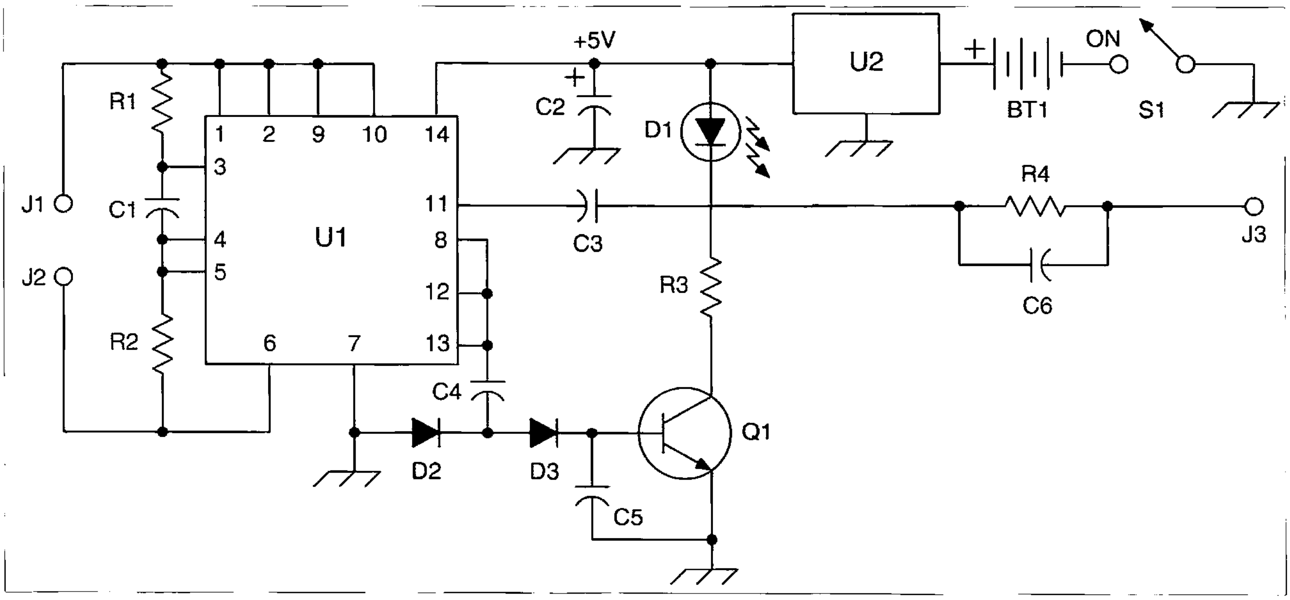

Fig. 1. Crystal matching and activity tester: simple version.

Power is supplied by a 9 volt alkaline battery (BT1) and is controlled by ON/OFF switch S1. Nine volts is applied to the input of U2, a 78L05 three-terminal regulator which produces a regulated +5 VDC for the circuit. The positive bus is bypassed by C2, a 10 μF electrolytic capacitor.

U2 is a 74LS00 Quad two-input NAND gate logic chip. The LS version was selected because of its low current requirement. Two of its internal gates are connected as inverters and, in conjunction with R1, R2, and C1, form a crystal oscillator when a crystal is connected between J1 and J2.

The third gate, also connected as an inverter, is used as a buffer to provide RF at the crystal frequency from pin 11, through isolation capacitor C3 and high-pass filter R4 and C6, to J3 so the crystal frequency can be monitored by an external frequency counter.

The fourth gate, also connected as an inverter-buffer, provides RF at the crystal frequency from pins 8, 12, and 13 connected in parallel. The RF is fed through isolation capacitor C4 to voltage doubling rectifiers D2 and D3, and the resulting DC voltage is filtered by C5 and, in the simple version, provides a positive bias to the base of Q1, an NPN transistor, which is normally cut off. Q1 goes into conduction and its collector current flows through LED diode D1 and R3 in series, both forming the collector load circuit. The greater the activity of the crystal, the higher the positive bias on the base of Q1 will be, and the higher its collector current will be. This current illuminates D1 and its relative brightness is indicative of the level of crystal activity.

In the deluxe version, the filtered DC voltage across C5 is applied to the positive terminal of M1, a 0-1 mA meter, whose negative terminal is connected to the wiper of R5 (a *sensitivity* potentiometer), one end of which is grounded. R5 is used to keep the needle of M1 on scale, and M1 indicates crystal activity level. Using this version makes it easy to match crystals of the same activity, or to select the one having the highest activity. The meter won't give an absolute value reading, but it can be effectively used for relative comparisons between crystals.

Construction

This tester can be constructed on a small piece of perf board, or on one of the small general purpose printed circuit boards available at Radio Shack™. It can also be built "dead-bug" style by gluing U1 and U2 upside down on a piece of wood or plastic. No enclosure is absolutely required, but if you expect to use this instrument a number of times it should be enclosed in an aluminum or plastic box, or in a case made of printed circuit board material. This is especially desirable if the deluxe version is constructed because the enclosure will provide a secure mounting for the meter.

J1 and J2 are specified as binding posts because most surplus microprocessor crystals are available in HC-18U or HC-33U cases with wire leads. Most other crystal case styles require sockets. Crystal sockets can be wired in parallel with J1 and J2 for greater convenience in testing various types of crystals.

The leads between U1 and J1/J2, plus any parallel connected crystal sockets, should be kept as short as possible.

The circuit between pin 11 of U1 and J3 should also be as direct as possible and its wiring kept away from the walls of the enclosure, if one is used.

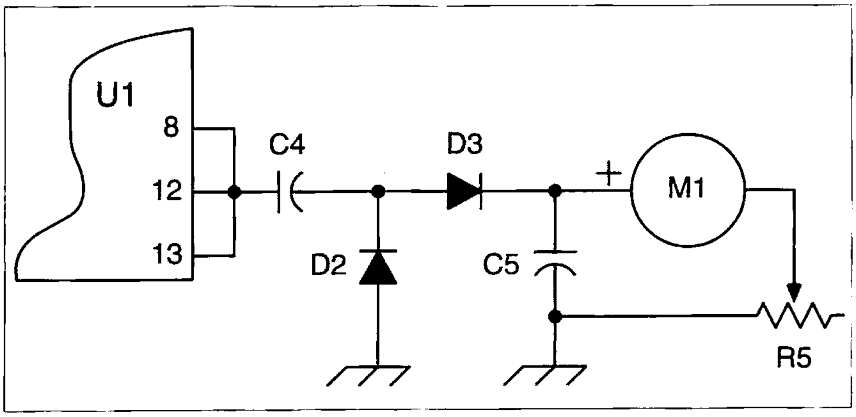

Fig. 2. Crystal matching and activity tester; changes for the deluxe version.

C4, C5, D2 and D3 should be physically close to U1. All other wiring carries only DC voltages and can be any reasonable length.

Operation

Operation is automatic. Set S1 to ON and connect a crystal with a frequency between 1 and 13 MHz between J1 and J2 or in a parallel socket. Observe the relative brightness of D1 in the simple version, or the indication on meter M1 in the deluxe version. Use the sensitivity control R5 to keep the M1 needle on the meter scale.

To measure the series resonant frequency of the crystal under test, connect the input of a frequency counter between J3 and ground and observe the frequency on the counter's readout.

Comments

This instrument is designed to function with crystals whose fundamental frequencies lie between 1 and 13 MHz. Some crystals slightly outside this range may oscillate, but this cannot be guaranteed.

A crystal which shows no, or very low, activity is either bad, suspect, or outside the range of this tester. Even if a crystal is marked with only a house number, instead of its frequency, it should be tested. It may very well be a useful crystal for you.

A sluggish crystal, one whose output level varies or which will not oscillate every time it is connected to this instrument, should be discarded unless it is in an FT-243 crystal holder. This special case will be discussed later.

Most crystals manufactured recently are sealed in metal cans. Normally these crystals are quite active and stable, although all crystals age, causing them to oscillate at a slightly different frequency than when first manufactured. If a crystal (within the range of this tester) in a sealed metal can refuses to oscillate, discard it. Perhaps the quartz blank is contaminated, or cracked, or one of the fine wires soldered to the metallized surface of the crystal has been detached. Rough handling, including simply dropping them on a hard surface, can destroy these crystals.

Restoring FT-243 crystals

Crystals in FT-243 holders, most of which are WWII surplus, often are available very cheaply at hamfest flea markets. Most are in the lower ham bands, or have frequencies suitable for multiplication to higher bands. Many of these crystals may either refuse to oscillate at all, or may be sluggish or have low activity, but many are easily salvaged unless there is internal mechanical damage.

You will need a brightly lighted work space, a clean, soft cloth to cover it, a pair of tweezers, a small Phillips-head screwdriver size 00 or 000, some alcohol (rubbing alcohol and vodka are suitable), and cotton swabs.

Spread the clean cloth over your work space. Using the small screwdriver, carefully remove the three tiny screws holding the metal faceplate to the plastic crystal holder.

Caution: Hold the metal faceplate firmly to the case while removing the screws. Do not allow the internal spring to toss the faceplate and crystal blank across the room!

Gently dislodge the faceplate and the rubber gasket behind it, and remove the spring. Set them aside for now.

The quartz blank, about half an inch square, rests between two very delicate thin brass plates. One lower corner of each brass plate is soldered to the holder pins. Gently shake the quartz blank from the holder onto your cloth work surface and set the holder aside.

Caution: Use extreme care not to break the connections between the brass plates and the pins. It is impossible to repair the holder in this case.

Very carefully, using a swab or the corner of a clean, soft cloth dipped in alcohol, clean the insides of both thin brass plates in the holder. Gently blow out or scrape out any loose dirt inside the holder. Set the holder aside to air dry.

Clean the crystal blank with alcohol as just described, using tweezers to hold it and move it around. *Never* touch the quartz blank with your fingers, and try not to breathe on it. When it is clean, set the blank aside to air dry.

Now clean the outside of the crystal holder, rubber gasket, and metal faceplate with alcohol, and set aside to air dry. Fold the clean cloth over all the pieces to keep them dust free. Be sure to allow plenty of time for the alcohol to evaporate.

When all is ready, pick up the crystal blank with tweezers and insert it into the holder between the two brass plates. Gently replace the spring on the outer brass plate, centering it. Then replace the metal faceplate and rubber gasket, gently forcing them against the spring until the three screw holes in the faceplate line up with matching holes in the plastic holder. Replace the three tiny screws, snugging them up firmly. Do not use so much pressure that you strip the threads in the plastic holder.

Clean off the outer surface and pins of the holder, then connect it between J1 and J2 or insert it in its socket. Turn the tester on and check for crystal activity and frequency. Chances are you will have salvaged a tired crystal and given it new life.

Parts List

BT1	9V alkaline battery
C1, C3, C4, C5	0.01 μF ceramic disc
C2	10 μF 16V electrolytic
C6	27pF ceramic disc
D1*	LED
D2, D3	Silicon diode: 1N914, 1N4148, etc.
J1, J2, J3	Binding post (see text)
Q1*	NPN 2N3904, 2N2222, etc.
R1, R2	560 ohm 1/4W 5%
R3*	300 ohm 1/4W 5%
R4	1.2 megohm 1/4W 5%
R5**	Øk ohm potentiometer
S1	SPST toggle or slide switch
M1**	Ø-1 mA meter
U1	74LSØØ
U2	78LØ5

*Used on simple version only.
**Used on deluxe version only.

About Surplus Crystals

Crystals can be, and are, ground to various tolerances, expressed in ppm (parts per million; hertz per megahertz). Close tolerance crystals can be very expensive. Most crystals on the surplus market have relatively wide tolerances. Microprocessor crystals, such as those sold surplus by many mail order parts dealers, are usually ground to a tolerance of ± 500 ppm—a half kilohertz per megahertz. A crystal marked "10.000000" can actually be anywhere between 9.995 and 10.005 MHz. The chances are very good that surplus crystals are mostly those whose frequencies fall outside even that wide tolerance. However, when used in transmitters, local oscillators, product detectors and BFOs, it is relatively simple to adjust the crystal to the exact frequency required. Most oscillator circuits contain trimmer capacitors that allow the exact oscillator frequency to be varied a small amount on either side of the crystal's resonant frequency. This process—called rubbering, warping, or trimming—allows precise adjustment of off-frequency crystals.

Crystals intended for use in an IF crystal ladder filter must be matched closely to each other in frequency to maintain steep skirts, although the exact frequency is relatively unimportant. So an 8 MHz crystal filter *might* have all 8.000000 MHz crystals in it, but it is far more likely that all crystals are somewhat below or above 8 MHz. But this filter still functions exactly as it was intended.

Microprocessor crystals, although marked with their *nominal* frequency to six decimal places, are manufactured specifically for use in either their series or parallel mode of oscillation. It is impossible to know which when you buy such a crystal. It also makes absolutely no difference because you are going to use it in an entirely different circuit than that for which it was ground.

There is always a slight difference in oscillation frequencies between a crystal operating in its series mode and the same crystal oscillating in its parallel mode. Regardless of the manufacturer's intent, you can use the crystal in either type of circuit, or in a filter.

Depending upon the circumstances, some circuits used by hams force the crystal to oscillate in its series mode, while other circuits force parallel mode oscillation. This instrument allows crystals to oscillate only in their series mode, at the fundamental frequency to which the quartz blank was ground. It is far simpler and cheaper to build an instrument to check crystal activity and frequency in the series, rather than in the parallel mode. Crystals used in the series mode, such as in IF filters and certain types of crystal oscillators, will be resonant at the exact frequencies measured by this instrument. When a crystal is used in a circuit where it oscillates in its parallel mode, it will produce a very slightly different frequency than that measured in its series mode. Usually, this will make no difference. Where it may be important, the crystal frequency can be easily trimmed to an exact frequency.

PVC Goes Camping

Full-time RVers, take note!

James Bassett KA1FPP/7
7420 Silver Leaf Way
Las Vegas NV 89117

Now that summer has arrived, it's time to get out the camping equipment. My list starts with: QRP rig, CW key, mike, coax, some wire, slinky...Did he say slinky? Did he mean the Slinky™ kids play with?

Yep, sure did. Seems the Slinky vertical fits into the camping box better than the 25-foot trap vertical or the poles needed to hold up a dipole. The Slinky is cost-effective; last time I bought one it was under $2.

Why a Slinky?

I camp quite often at the Lake Mead National Recreation Area. The total number of trees is zero, meaning that any antenna must be self-supporting. The soil in the area varies from soft silt to hard as cement, making it necessary to devise a method that will not require that the ground conductivity be a factor. The structure supporting the Slinky must be flexible, lightweight, strong, and easy for one person to manage. With these requirements in mind, I designed the Slinky Vertical. A standard Slinky serves as the main radiating element, and common PVC tubing provides the support structure. The resulting antenna is quickly assembled, easily moved, and can be stored in a very small space.

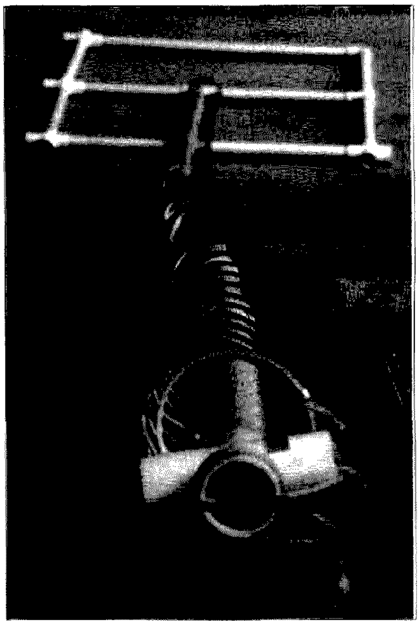

Photo A. The top guy ropes are tied to the upper PVC cross before the antenna is erected.

Construction

The PVC is cut into sections that fit into the bottom of my camping gear box. This makes it easy to store and carry. Other PVC pieces required include: double females, tees, and crosses. Precutting several pieces at home to form the base saves time later at the campsite. My version used a square base, but feel free to modify the dimensions to fit your particular application. This system is assembled on the ground and set upright when completed. A T-shaped PVC piece is required in the center of the base to control the bottom of the vertical support. Two of the vertical support pieces must have 1/4-inch holes drilled through one or two inches from the end. Two 6-inch by 1/4-inch dowels inserted through the holes will secure the Slinky to either end of the PVC mast. The remaining sections with associated female connectors are assembled to make the vertical support. The PVC pieces with 1/4-inch holes in them are placed at the top and bottom of the vertical support assembly.

Insert a dowel into the lower section of the support; it can be held in place by a rubber band. Place the Slinky over the support, hooking a couple of coils over the dowel. Put the other dowel in the upper support, then stretch the Slinky along the full length of the PVC assembly, hooking a couple of coils over the upper dowel. Again, a rubber band can be used to hold the dowel in place. Place a PVC cross-shaped piece on the top. Attach lightweight guy lines to this tie point. (*Caution: Depending on how tall you have made the support, you may need guys in the middle to keep it from bending.* A PVC cross may be placed in the middle of the vertical support as a tie point. Experiment at home before going camping.)

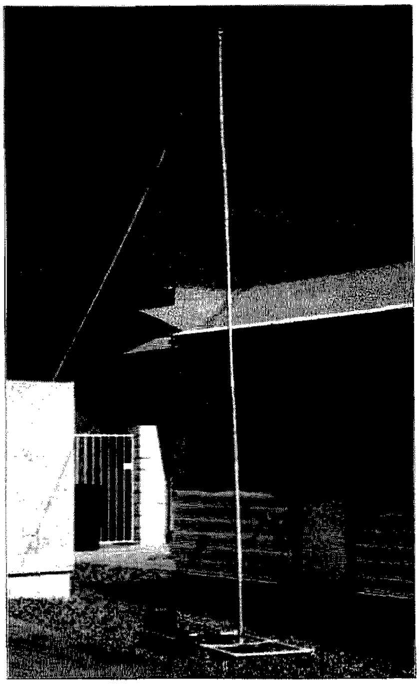

Photo B. Entire station set up at home, prior to going camping.

Now the tricky part: Tie off two guys loosely with enough slack to allow the antenna to be placed upright. Stand the structure up and tie off the third guy. Now go to each guy and adjust accordingly. The antenna shown in the photos is 13 feet tall and works well with just top guys.

The Slinky will stretch taller; in that case you will need to guy the structure in the center. I've used it to 18 feet with two sets of guys. The length of the Slinky if it's stretched out is approxi-

mately 67.5 feet of radiator, close enough for a quarter wave on 80 meters. This configuration is a high Q design. To lower the Q and increase the bandwidth, add a capacitance hat. You can use a short vertical rod or a round piece of metal for the hat. The vertical rod is the easiest to use. Simply tape it to the PVC and use a jumper from the Slinky to the rod. If you plan on running high power, the hat is required.

If you camp where there is no place to anchor the guys, you'll need to improvise. I've used my spare tire, tools, the camping box partially filled with sand, a garbage bag with sand, or whatever was handy. The entire antenna system only weighs a few pounds but your anchors should be heavy enough to hold it in place if the wind picks up. Use your imagination and have some ham radio fun.

On the air

Well, that took 15 minutes, so let's get on the air. Gator clips were preinstalled on the coax so connect the center lead to the Slinky, the shield clip to the ground wire, and the other end of the ground wire gets thrown into the lake. When the lake isn't available I just make a wide circle around the base of the antenna. Either way, it radiates. You may want to cut radials for each frequency you will operate.

I've found most campgrounds don't have enough room to string out a standard set of radials. In this situation, run coax into the back of the rig. Hook up the rig to the coax, power supply, CW key, and mike. Turn on the power supply and the radio. Now the magic...check the SWR...ouch! Sure is high...unkey the radio, run over to the base of the antenna and move the clip on the center lead up the Slinky...recheck the SWR...ouch!...(still high, but better). Keep up this procedure until the SWR is acceptable.

If you want to save the running back and forth, here are two suggestions: 1) Use a tuner and you are on the air in minutes; or 2) Use one of the antenna analyzers on the market. It will tell you almost instantly how far off frequency the antenna is and makes the adjustments much easier and faster. I've used both methods and prefer the second.

***Photo C.** The left clip is from center lead of coax to Slinky; right clip is shield of coax to radial; 1/4-inch dowel holds Slinky in place.*

Complete campsite station requirements are listed in the sidebar. *Important: Know what kind of connectors you need to make everything work together before you leave home!*

Minimum Requirements for a Successful Ham Camping Trip:

Transceiver
CW keyer
Microphone
Slinky™
Power supply with cables to attach to the radio (match power supply to the transceiver's requirements)
Guy lines (heavy twine works)
Guy line anchors
PVC (approximately 20 feet) with necessary elbows, tees, and crosses
Coax with clips installed on one end and proper connector on the other to fit the radio
Scratch paper
Log
Pencil
Ground wire/radials
Spare fuses

Optional:
Tuner
Antenna analyzer
Headphones
Speaker
Tape
Metal plate or rod

NEVER SAY DIE

represent amateur radio at the WARC conference at the ITU in Geneva?

Adventures like this are there if you keep your eyes open. And ears. Even ham visits to the Caribbean can be a ball. It doesn't cost much to get on the air from any of the islands down there. And the local hams are wonderfully friendly. But then you haven't bothered to send for my *Caribbean Adventure* book yet. Tsk. How about an inexpensive bed and breakfast on Montserrat, complete with an operating ham station and swimming pool?

Or the time I heard that King Hussein JY1 had gotten on the air. Most hams did nothing. I cabled him and asked if he needed some help with the pileups. A few days later I was on my way to Jordan and an incredible adventure.

So what's your excuse? Is it a lack of initiative? Laziness? No motivation? No determination? No guts? None of my adventures would have happened if I hadn't taken some initiative. I find you can do almost anything if you decide to and then stick to it. That's how I took off nearly a hundred pounds of lard which I'd been lugging around for many years. And I've kept it off.

But, you know, I get discouraged. When I preach adventure you head for the couch and a ball game with a six-pack in hand, or for a rag-chew about nothing on 75m. I try to explain how you and your family can live a long, healthy life and you get mad because I'm not writing only about ham radio. Sigh.

Maybe there is no way to motivate the grossly fat hams I see at hamfests to add years to their lives, or to get the average ham to even consider volunteering for an adventure.

I remember the time I organized a ham tour of Europe. 73 of us visited London, Paris, Geneva, Rome and Berlin, and we had a fantastic time. We had ham parties in every city except Rome, but we did have an audience with the Pope there. And we pulled off the whole tour for $550 a person, and that included nice hotels, great parties, and all flights. That was the normal round-trip tourist fare to Rome at the time, to give you some perspective on how inexpensive it was.

You won't believe how cheap you can travel unless you start reading my two $8 travel books.

I wanted to put on another European tour, but the ARRL had proposed what they called "Incentive Licensing" to the FCC and the whole ham industry was being destroyed. It was really tough on my upstart magazine when 85% of the ham radio stores carrying it went broke and over 90% of the manufacturers went out of business. Hams by the thousands, in a panic over the proposed legislation, sold off their stations for anything they could get for them, all in a couple of years. The hobby has never really recovered.

But even with the hobby in deep trouble I was having fun and adventure. I found a house for sale high up on the highest mountain in southern New Hampshire, just a few miles from my home. There I set up the darndest VHF ham station, with four big towers and huge antennas. On 2m I had 336 elements, fed by a kilowatt, and two kilowatts of audio for the AM signal. Talk about punch! My signal over the whole east coast was legendary. I worked walkies down in New Jersey, 250 miles away! Expensive? Of course not. I swapped advertising for the ham gear and towers, and had the help of $20 a week plus room and board college drop-out hams in setting up and operating it. We were all living and working in my 40-room house, with me cooking all the meals.

Now, let's talk about what adventures you've had so far. Adventure is right there, waiting for you.

Pioneering new communication modes is an adventure too. As soon as I heard about Jack Babkes W2GDG inventing narrowband FM, I modified a BC-459 exciter and was giving it a workout on the air. Now NBFM is mostly what we use on 2m and up.

I built an SSB rig and got on the air with 5 watts and a dipole antenna on 20m. My first contact was with Australia! And so it went with RTTY, slow-scan, and repeaters. I was the first ham on 6m in New York City. I helped W2BFD put up the first repeater in the east so all the RTTY gang could communicate. If you don't think putting up a repeater antenna on top of a New York skyscraper in a snowstorm in the middle of the night is an adventure, then take a look at the Municipal Building roof some time. It's copper-clad and has a 30° slant. I had to hold onto the little pegs fastening down the copper plates to keep from being blown off the roof. How about working seven states on 10 GHz with a tenth-watt little box for adventure? Or talking to hams all around the world via moonbounce using the thousand-foot dish at Arecibo?

Good grief, are you still just sitting there? There isn't one thing I've done that others couldn't. It's just a matter of initiative.

More Surplus Coming?

The FCC is considering "refarming" the frequencies below 512 MHz. By that they mean narrowing the bandwidths permitted. While the commercial companies providing the communications services will benefit by being able to service twice as many users, you can bet that the users of those channels will be fighting the move since it'll mean a massive obsoleting of their equipment. Users will have to get new rigs to meet the new restrictions.

It was just such a move about 35 years ago that obsoleted tens of thousands of taxicab radios and their communications systems, when they went from 30 kHz wideband FM to 15 kHz. It was this massive changeover that sparked the amateur radio 2m FM and repeater revolution. The first repeaters were on 30 kHz channels, starting at 146.64 MHz and going on up to 146.70 (which was an RTTY channel early in the game), 146.76, 146.82, 146.88, and 146.94. The 60 kHz separation allowed for the 30 kHz bandwidth of the users without too much interference from the adjacent channels.

It wasn't long before we had to go to narrowband FM, as pioneered by W2GDG back in 1946. He later formed Sonar Radio to market the mode and made millions. That allowed twice as many channels. And when those filled up we started using the 147-148 MHz segment too. Eventually that filled up, so we narrowed down our receivers even more, doubling the number of channels again. I won't get into a discussion on how much we're using all of those channels. I suspect that the goal for most hams is to have one channel for every ham for his repeater, and never mind that there is no one left to use it but him.

If the FCC is successful in forcing the commercial users below 512 MHz to buy new equipment, we're going to have a ball with all that cheap surplus mobile equipment. It's also going to be a bonanza for the equipment manufacturers, generating billions of dollars in sales. Of course this is going to tend to raise our state and federal taxes, because our blessed government is a big user of these frequencies.

The downside is that with all this great, cheap equipment, we may not have any frequencies left we can use it on. But that's pretty much up to you and whether you and your club are interested enough to put up a fight.

The Internet

I recently pointed out that the Internet is posing more and more competition to ham radio. Now you can chat with people almost anywhere in the world without any worry about QRM and propagation. And cellular telephones have taken away most of the need for our ham repeaters for emergencies, making them largely an improved CB type communications system for Techs.

Maybe what we need now is a special section on the Internet just for hams. We should set it up so it will provide the ability to make a contact with people around the world only when 20m propagation would normally permit it. We'd have a computer generate crosstalk, fading, and other normal interference, to provide realism. Contacts would be limited to one minute, tops. Of course we'd have simulated pileups on the rarer countries.

For further realism, we'd charge 10¢ a minute for a simulated 10-watt signal, 20¢ a minute for a 100-watt signal, and 40¢ a minute for a kilowatt signal. A California Kilowatt signal would cost a buck a minute, and be well worth it! How about 1-watt signals being free? Sure, why not?

This contest, like DXCC, could run 24 hours a day, 365 days a year. Hmm, if we figure that this would be restricted to 25 kHz of the 20m band, that would mean about five channels. This would take five channels on the Internet. No problem.

When I spent some time working DX from Afghanistan as YA1NSD I noticed that the Big Signal US hams were in there solid every night. The plain old kilowatts with triband beams came through about four

nights a week. The 100-watters maybe one night a week. The 10-watters maybe one night a month. That wouldn't be difficult to program into a computer.

All you'd need is the bucks and the time, and you'd have your 400 countries worked, just like on amateur radio. Once I got a kilowatt and a good beam working up here in New Hampshire I worked 100 countries in a week, 200 in a month, and 300 in less than a year. But then I had to take some time away from operating to put out *73*. With so many hams retired, many should be able to easily beat my record. I did once work 100 countries in a weekend on 20m phone, but that was during a contest. I just wanted to see if I could do it.

With the FCC under pressure from Congress to sell off as much of the spectrum as possible, and with us having more spectrum allocated than any other service, we'd better start making plans for meeting the communications challenges of the 21st century. But without counting a whole lot on using radios. Maybe we can at least keep the spirit of amateur radio alive via the Internet. Will Dayton have to hold yearly InterVentions?

Is CW Dead?

Somehow I've managed, in some minds (?), to come across as a CW-basher. Piffle. I'm a basher of the use of the code as the major barrier to keep new hams away from the HF bands. As I've mentioned, probably too many times, it was my code skill that saved me and my submarine during WWII. I have always championed the use of CW as a fun mode for hamming. It's great for DX contacts where English is a barrier. And, for those who are proficient, it's a great way to communicate.

If the code hadn't been mandated by the government I probably would have enjoyed it. But I have a serious, probably genetic problem. When someone forces me to do something that doesn't make any sense to me, I resent the hell out of it, and I resist. I've checked a couple of my past lives and, sure enough, I was a troublemaker there too. I had problems with my folks when I was young. "Because we told you to," wasn't enough of an answer when I asked why I should do something, even when it meant a spanking.

The Navy and I had some problems with this. They operate on this weird slave-type system of they tell you to do something and you do it. It took me a while to adjust the Navy to my thinking. Well, I didn't have much success with the whole Navy, just with those around me. Ask me and I'll do almost anything. Tell me, and you can go to hell.

Anyway, let's stop this stupid idea that I'm a CW basher. I do think it's a good idea for survival trainees to know the code, just in case. It sure helped Scott O'Grady get out of Serb-held Bosnia when his plane was shot down. But then he had to use voice to confirm his identity. You don't need to be a 35 wpm speed king for that, you just have to have memorized the Morse alphabet. And that only takes a few minutes put of a whole lifetime.

I do wish that there were more people who would demand reasons for doing things and not just meekly follow along, head down, sheep-like, doing whatever someone else tells them to. That's all it would take to clean up the lousy government we've allowed to build up. Can you point to one major social problem in America that hasn't been caused by the government you elected? And continue to re-elect? One? Hmm, let's see, what time is Roseanne on tonight? And The Simpsons?

Pioneering Opportunity

An item in a recent *Fortune* on how to cut your phone bill by 96% attracted Wily Wayne's attention. I'm not cheap, I'm just thrifty (Never Squander Dollars). So I looked into it. What VocalTec has is a software package ($59) which allows computers to send voice over the Internet to anyone else using the same software. It uses data compacting and allows one-way ham-type communicating anywhere in the world via the net. For $1 to $2 an hour vs. about a buck a minute to talk with someone in Hong Kong!

Instead of brooding over this latest Internet assault into ham territory, I said to myself, hey, how about using this cutie to narrow the bandwidth of our voice transmissions? If I don't start hearing the sound of this strange new data swapping on 20m soon, followed by some enthusiastic articles submitted to *73*, I'm going to put you down as being lazy, brain-dead, good-for-nothing, soap opera watching, beer swilling couch potatoes.

The system is set up to use a 486 PC with at least 8MB of RAM, Windows 3.1, WinSock 1.1 14.4kb modem, and a Windows-compatible sound card, microphone, and speakers. VocalTec is at 157 Veterans Drive, Northvale NJ 07467. 201-768-9400, Fax: 201-768-8893. E-mail: info@vocaltec.com. Okay, VocalTec, where's the Mac version? Drat!

Curt LeMay

I had a chance to talk with General LeMay, the head of the Strategic Air Command (SAC), one time at a Sideband Dinner in New York. Curt was blunt. And salty. Curt explained the facts of life to me, and they're worth repeating now. He explained that amateur radio existed as a "service" (read: hobby) for one reason and one f— reason only: The military wanted it. There were two reasons for our military support. Number one, the military wanted to have a bunch of frequencies available they could take over in time of war that weren't cluttered up with the much more difficult to move commercial and broadcasting services. Number two, in case of war they would need men with technical know-how to install, operate, and service electronic equipment.

He was right. At least he was right during the 1930s to 1960s. As I've mentioned, when WWII broke out 80% of the licensed hams

Continued on page 42

NEVER SAY DIE

Continued from page 41

joined the military, giving our country a tremendous technical edge over Japan and Germany. And it was our electronic technology that won that war. I was there in the front lines, so I know personally what a difference it made. We also donated our ham receivers to help the government. My SX-24 went to war in Brazil with the OSS' Rubber Development Corporation. And I went on a submarine, where I helped sink a lot of Japanese ships.

Today we hams have almost nothing to offer the military. Future wars will be high-tech, but they'll be short. It took us almost two years after WWII started before we really got going with effective radar and sonar. Heck, when I reported aboard the Drum in 1943 we were still using a TRF receiver for low band reception! That design was close to 20 years old by then.

The military has no further need for our ham bands in emergencies. Our ham equipment would be useless for them too. And I'll bet not one ham in a thousand could service the latest military electronic systems. Sure, we could field several hundred Morse Code experts if an enemy bombed us back to the stone age.

They had quite an article on LeMay in the *New Yorker*. It wasn't flattering, so I was just as happy that they didn't mention his being a ham operator (W6EZV), or his part in the promotion of SSB. According to the article LeMay was ready, with or without presidential authorization, to nuke Russia in a preemptive strike. I've written in my past editorials about how Art Collins WØCXX of Collins Radio, with the help of Don Merton K2AAA/W2UOL, got the Air Force to make SSB their standard for voice communications, beating out GE and John Costas K2EN with his technically superior double-sideband system.

Help!

Hey, some of you retired old timers, when it's too wet to play golf or the football game has been canceled on TV, if you have some art skills, maybe you could give me a hand in your spare time. I'd like to use more drawings, cartoons, and other ham-oriented artwork in *73*. I could even use some help in doing schematics, if you've got a good software program for that. Bandel Linn K8LAP did my cartoons for years, but he smoked, so he died in a nursing home. I met Bandel in 1950, when I was working at WASP in Sarasota (FL), where he did a talk show interviewing famous people living in the area. For instance, I got to know author McKinley Cantor through Bandel.

The two of them had a great friendship, with one always trying to outdo the other on practical jokes. Like the time Cantor bought a whole bunch of used books for a quarter each. He stamped Bandel's name and address in them, offering a reward for their return. He then left them all around the country in hotel rooms and stores where he was autographing copies of his books.

Let me know if you've managed to develop some art skills, or at least can handle computer-generated schematics for me. I want to make *73* more fun to read. Yes, of course I'll pay for the work. But not a whole lot. Remember that NSD stands for Never Squander a Dollar.

Antenna Gestalt

How would you, once and for all, like to actually understand how and why antennas work? The basic theory isn't complicated, once you go for the concept instead of being buried in operational details.

For instance, why do beam antennas have gain? Well, that's simple. We have to have a reference antenna to compare to a beam, so we use a dipole, which is a piece of wire cut to one-half wavelength long at some designed frequency. Now, if we're radiating 100 watts from an antenna, that 100 watts is going out in all directions. If we could have an antenna that acted like a point source, our 100 watts would be spread out evenly in a sphere.

So, if we put a mirror under the point source, reflecting back all of the energy normally going down, we'd have our 100 watts being distributed through just half of a sphere, so we'd have twice as much energy at any one point on the half-sphere. Thus, the more we can focus the energy from the antenna in one direction, horizontally or vertically, the more gain we're going to have in a desired direction.

For most of our antennas the earth (aka ground) acts as a mirror. It's a murky mirror, sopping up some of the energy instead of reflecting it all. So we often try to help Big Mutha do her reflecting work with a ground plane or, on the lower bands, a bunch of ground wires under the antenna. The less energy we spend heating the earth and reflecting back into space, the more energy we'll have available to get a signal out. And in, too. Antennas are reciprocal devices, which means they work just the same on sucking in energy as transmitting it.

On the lower bands we have a series of ionized layers of air a few miles up in the (surprise!) ionosphere. These are ionized by being zapped by energy coming from the sun, so the more sunspots Old Sol has, the more stuff that erupts from its surface in solar flares, and the more the earth gets bombarded by with ions. These layers also act as foggy mirrors. The stronger the ionization, the better the reflecting ability of the layers.

The higher we go in frequency, the higher the layer that will reflect our signals. This is why we have such a short range on 80m, and such a long range on 10m. The higher the layer doing the reflecting, the further the signal is going to be reflected. And then we're helped by it bouncing back and forth between the ionized layer and the earth's reflection, giving us multiple bounces.

And this is why, during sunspot minimums, the higher layers don't get enough ions from the sun to reflect our signals, so 10m dies, and even 20m is lousy at night. As soon as the sun's ions stop zapping the ionosphere, it starts to disperse, hence the different propagation at night. The higher layers disperse the easiest, so 10m fades out at night, even in very high sun spot parts of the 11-year cycle.

Once we get above the highest frequency these layers can reflect, which we call the Maximum Usable Frequency (MUF), we're up in the VHF and UHF bands and antennas are simpler to deal with.

On the lower bands you have two needs. One is to be able to hear signals from all directions when you want to. It's nice to have a clue as to what areas of the world the ionosphere layers are favoring. But then you want to concentrate as much energy into the one single direction as you can so you can be heard, and can hear the chap you're trying to contact and cut down on the signals from other directions. This is tricky. You want to concentrate your energy both horizontally in as narrow a beam as you can, and also vertically, aiming it upward at an optimum angle to bounce off the ionosphere. And that vertical angle is always changing as the layers go up and down, and different layers come into play at different heights. The ideal DX antenna would be steerable both vertically and horizontally. Well, that isn't difficult for the UHF bands, where your antennas are small. A half-wave at 2m is about 38" while at 20m it's obviously ten times that, 32 feet. That's beyond what we can practically do with an az-el rotator. Azimuth (horizontal). Elevate (vertical). We use those mostly for our satellite communications up on the VHF and UHF bands, where we zap right through all those ionosphere layers.

One of the problems with this vertical angle deal is that an antenna which works great during the high sunspot years because it has a particularly low angle of radiation, is a dud when the sunspots are low and the lower layers less ionized. For instance, the W8JK "Twin-Three" wire beam is a marvel during the high sunspot part of the cycle. It has a very low angle of radiation. I knocked the socks off the Big Signal boys with their yagi beams with this simple wire antenna. It's just a couple of dipoles spaced 1/6th wave apart. It's bidirectional horizontally, and doesn't have much more horizontal directivity than plain dipoles. But it had a very narrow vertical angle, and very low. The result was that my signal would be the first heard when the band was starting to open, and the last to fade out. But while the band was wide open, I was outdone by the yagi antennas.

So when everyone was working Europe, I'd call CQ the Middle East or the Indian Ocean. When everyone was working the Pacific Ocean and Japan, I'd be working far into China, South Africa and the Middle East the long way around. I remember working W5IMW portable in Tsientsin, China, running a quarter watt (AM!) to modulated signal generator into a longwire antenna. He

The "J" Antenna

An oldie but a goodie.

Dale R. Kubichek N6JSX/9
1305A South 13th Street
Manitowoc WI 54220

The "J" antenna goes back many years, long before I became a ham. There are a bunch of reasons why you're going to want to build one of these beauts:

- It has a low, relatively straight-out angle of radiation.
- No ground plane is required.
- You can use it on several bands.
- It may have separate feeds for each band.
- It's very easy to make.
- It's inexpensive to make.
- It's fine for mobile, marine, or home use.

I run 2 meters and 220 MHz in the car, and I prefer a solid gutter mount over magnetic mounts. A 5/8- or 1/4-wave whip antenna on the gutter only has half of the car's body to act as a ground plane, but the "J" requires *no* vehicle ground plane.

The "J" is the *best* antenna for flatlanders, giving the most distance to your transmitted signal. This is due to the exceptionally low, to nearly flat, angle of radiation of about 0°-2°. The other, more common, antennas give much higher radiation angles; that may be good for mountaintop elevated repeater sites but will shorten your overall flatland transmitting distance. The 5/8-wave whip has about a 4°-6° radiation angle and the highest radiation angle comes from the 1/4-wave whip that has about 5°-10°. The "J" has approximately 3 dB of gain over a quarter-wave ground plane antenna and 6 dB over an isotropic (theoretical) antenna. The "J" can be made from almost any material: copper pipe, steel whips, and even 300 ohm TV twin-lead.

Technically, the "J" antenna is an end-fed half-wave antenna that uses a quarter-wave matching stub. Old-timers might call it an "end-fed Zepp," bent 90°. In actuality, the conductor is three-quarters of a wave long and the remaining section is a quarter-wave long. The matching stub creates the tuned half-wavelength antenna. Because the matching section acts as the matching transformer/balun, the half-wave radiator sees the lower quarter-wave

"The "J" is the* best *antenna for flatlanders, giving the most distance to your transmitted signal."

	146 MHz	223.5 MHz	446 MHz	
1/4 Wave	19.3"	12.6"	6.3"	computed
1/2 Wave	38.5"	25.1	12.6	values
Radiating Element	57.5"	37.5"	18.5"	
Matching Element	19"	12.5"	6"	
Coax Taps				
Combo 2m/220	5"	2.25"	n/a	
Combo 2m/220/440	4"	1.75"	1.25"	
Spacing Between Elements (ID)	1.5-3"	1-2"	0.75-1.5"	

(The spacing ID can be as small as 1/4", but the coax taps' dimensions will be affected.)
NOTE: These same dimensions are also good for monoband designs—specifically for copper pipe "J"s.

Table 1. Copper Pipe "J" Antenna Dimensions

	144 MHz	220 MHZ	
Radiated Element	57.5"	37.5"	
Matching Element	19"	11.75	No tuning required
Coax Taps	3.75"	1.5"	No tuning required

Table 2. TV-Twin "J" Antenna Dimensions

matching section as an image of a false ground plane. In best terms, the "J" is a balanced quarter-wave matching stub feeding an unbalanced half-wave load. The feedlines to a "J" can be almost anything (ladder line to coax). Through experimentation, I found RG-58/U coax to be quite satisfactory.

The "J" antenna designs I have built and tested are:

- 3/4", 1/2", & 3/8" copper pipe
- 144 & 220 MHz combo
- 144, 220, & 440 MHz combo
- 2m modified CB whip gutter mount
- 2m & 220 TV twin-lead 300 ohm
- 144 MHz monoband
- 220 MHz monoband
- 430 MHz Beacon/ATV monoband

The "J" antenna can be made of common 1/2" rigid copper pipe with copper tees and 90° elbows. These copper parts, plumbers' flux, solder, and propane torches can be obtained at most hardware stores. Copper pipe is easy to solder, which makes assembly a snap, and these materials will withstand a lot of abuse and weather.

Modified CB whip "J" antenna

For a mobile 2m "J," I used a Radio Shack™ 102" CB whip and cut it down to size. The whip comes with a 3/8" x 24 mounting bolt attached to the bottom of the whip that fits nicely into most Radio Shack (gutter, ball, or mirror) mounting clamps. I made the plastic insulators and metal support brackets. I drilled the electrical split-bolt connectors to slide on the whip and give mobility to the coax attachment for adjusting VSWR.

I've modified my initial 102" CB whip "J" antenna design even further by welding an "L"-shaped 10 gauge bent metal rod matching section only about one inch away from the whip. The bottom of the "L" was welded to the whip bolt-head making a clean, sturdy construction. This eliminated the metal support bracket fabrication and made the antenna more aerodynamically stable, reducing wind loading and stress on the vehicle mounting point. I found the other metal support bracket loosened due to vibration and excessive wind flexing of the antenna.

"The portable version can be rolled up into a coil and stored in your desk drawer, or even carried in your pocket."

Triband copper pipe "J" antenna

On the three "J" antenna combo, I took the matching elements and placed them 120° from one another. This appears to help eliminate crossband RF desensitizing. Tune the 440 section first and then the 220 section with the 440 section disconnected, and so on. The rigidity of the copper pipe means that insulators between the matching stubs will not be required to keep the elements equidistant. Use silicone on the antenna feed points and coax for weather protection. After building this triband "J" antenna, one apartment-restricted ham took this design, added a copper pipe stand to the base of the combo antenna, and made it a hat/coat rack in the corner of his apartment. He ran the three coax cables along the mop boards to his ham desk, and he claims the antennas still work well even with a few coats hanging from the "J" elements. See **Table 1** for measurements.

Emergency portable "J" antenna

This antenna can be rolled up into a coil and stored in your desk drawer or even carried in your pocket. With a rubber band, paper clip, or thumbtack, the "J" antenna can be suspended anywhere. This antenna makes a fantastic sneaky "hidden transmitter antenna," and building it is easy. You'll need:

- 60" common TV twin-lead
- RG-58/U coax (multiples of odd 1/4 wave length)
- Coax connector (PL-259 or BNC type for HTs)
- Soldering iron
- Paper hole punch

See **Table 2** for 144 and 220 MHz antenna dimensions.

Install tap-offs at the indicated points and trim the matching element in small increments until you have the best SWR. Be sure to add a little length to the matching element if you're going to tweak the SWR. I have placed a TV-Twin "J" inside PVC plastic tubing for weatherproofing and making a rigged antenna. Paint the tubing black, put a hook on the top, and you have an invisible nighttime antenna. (The PVC tube *will* interact with the "J" so special tuning is required.)

Special note: Since 1984, when I began pushing the "J" antenna design in *ALLUSA* packet articles, I have seen many published articles covering the TV-Twin-lead "J" with many different antenna dimensions. What I've been able to discover is that the length of the coax attached to the TV-Twin-lead "J" directly affects the dimensions and performance of the "J" antenna. However, using a bazooka balun (i.e., tuned RF coax shield choke) at the feed point of the coax seems to nullify the variable effects of random lengths of coax.

"J" beam antenna

A copper pipe monoband "J" is the basic foundation for my extended three-element "J" beam design. This beam can be made from any monoband "J" design. See **Table 3**. My extended three-element design gives nearly as good a performance and gain (about 6 dB) as a four-element antenna. The matching element can be as close to the radiating element as practical (but any variance in this dimension will directly affect the coax

	144 MHz	220 MHz	440 MHz	434 MHz

Table 3. "J" Beam Antenna Dimensions

taps.) The antenna offers good directivity and the potential for some interesting mechanical methods of changing beam bearings. Remove the pins from the PVC, and the beam makes a great rotating hidden transmitter antenna. I have rigged this beam for a constant (2 rpm) slow rotation (using a 12 VDC windshield wiper motor), making the signal bounce and scatter all over the hills. I used a glass marble for a mock bearing between the top of the radiating element and the PVC end cap.

Since moving from my California home in 1993, I've been living in an apartment, unable to use outside antennas. I use "J"s for all my VHF/UHF/packet operations inside the apartment. Placing the antennas in the corners of the living room, hanging the "J"s from curtain rods (behind curtains), or using a TV-Twin "J" thumbtacked to the roof of the patio room allows good ham communications, and I can keep my PTM packet mini-BBS station (in Manitowoc, Wisconsin) on the air. The "J" antenna offers the foundation for stealth antennas; by placing the antenna in PVC, with a little paint and an angled mounting box, the antenna can look like a gas/sewer breather pipe on the roof of an apartment or CCR restricted house. I have found the 3/4" copper pipe "J" to have a broader bandwidth, and it's extremely sturdy, making it a good high-wind area antenna when solid coax attachments are ensured. A coat of polyurethane will keep the antenna bright for years.

Other good "J" antenna designs that have been published in *73 Amateur Radio Today* in recent years (in my opinion, the best "J" designs, offering the greatest potential, are the 2m & 440 dual-banders):

- "Copper Cactus J-Pole" by KE7AX, February 1992.
- "Copper Dual-Band Super J-Pole Antenna" by KAØNAN, April 1993.

Other interesting designs are:

- "220 Super J-Pole Antenna" by KAØNAN, May 1996.
- "440 Super J-Pole Antenna" by KAØNAN, April 1996.
- "Simple J-Type 10m Vertical" by W6IOJ, September 1995.

NEVER SAY DIE

Continued from page 42

said I was the only one on the band he could hear.

Twin-Threes got to be fairly popular during the high sunspot part of the cycles, and then died when the spots died down. By the next cycle they'd all been replaced by higher angle radiators, so eventually the Twin-Three has been lost in history. You don't even see it in the antenna books any more.

Ham Myths

An editorial in *Florida Skip* decried the decrease in technical competance brought on by the opening of the gates to no-coders, who the author, John Weatherly AB4ET, claims are flooding our bands. Alas, John, not having been licensed for long, has no way of comparing today's hams with those of yore. Having been there in yore, I know all about the vaunted technical competence of that era.

What a bunch of mitigated crap. The hams of the 1930s didn't know squat. They built their transmitters by copying articles in *QST* and *Radio*. Sure, back in the 1920s hams built their own receivers. But as soon as the first commercially made receiver hit the market they all stopped building and bought them. They had to build their own transmitters up until WWII because there no commercially made transmitters. Well, hardly any. Yes, National made a National 600 in 1939, but it was $600 and ran 600 watts. And that's like about $12,000 in today's dollarettes. It was a nice rig, with 100THs in the final. Thordarson power and modulation transformers. Nothing but the best, but not exactly what the average 6L6-using ham was looking for.

The big rig of the late 1930s was the QSL-Special, 6L6Gs on a chassis the size of a QSL card, with plates running red hot with the key down.

When I got interested in hamming I was a 14-year old kid, so I marked a map of Brooklyn with the location of every ham in the *Callbook* and I set about visiting as many of them as I could, zipping around the borough on roller skates. I listened on 160 and visited. I listened on 40m. 10m. There wasn't much doing above 10m, which was the microwaves of the day. I visited around a hundred hams and talked with them.

Here's a report on what I found in 1937-8. I found one ham who had built his own receiver. One. The rest had built their transmitters, but they had little understanding of what was going on in them. After they finished building their rig many of them had to bring it over to Cy W2IXY to see if he could make it work. His main piece of test equipment was a neon bulb.

So let's not perpetuate the myth of ham technical competence of yore, using it to try and make newcomers feel guilty and inferior.

The flood of war surplus in 1946 did more to help build ham competence than anything

Automatic Voltage Controller

J. Frank Brumbaugh KB4ZGC
PO Box 30, C/O Defendini
Salinas PR 00751-0030

Did something blow up in your regulated power supply and suddenly feed 25 or 30 volts into your expensive solid-state transceiver? Did you ever damage a storage battery by draining it completely? Here is a simple circuit that will cost only about five dollars to build, and will prevent damage to your equipment should your DC source voltage vary outside safe limits. The limits are defined usually as being +11.2 and +15 volts DC for most solid-state ham equipment.

This circuit can be thought of as a tireless "robot" that continuously monitors the DC voltage level of the power source for the ham station, whether storage batteries or regulated power supply. Because solid-state equipment can be damaged by excess voltage, and may not function properly when the supply voltage is too low, this "robot" will remove the DC voltage from the station equipment immediately should the voltage vary outside safe limits. At the same time, it will alert the operator with a red LED, and a bell or piezo warning, if included as an option. Thus, repairs and adjustments can be made immediately to bring the DC voltage back to safe levels. At that time this "robot" reconnects the DC voltage to the station equipment and indicates that all is well by turning off the red LED and the optional audible alarm and by illuminating a green LED. Operation is entirely automatic. Voltage limits are established by the circuit. Setting two trimpots for each voltage limit establishes calibration for normal operation, as just described.

Theory of operation

Refer to schematic diagram **Fig. 1** for the following discussion. Station DC voltage, a nominal +13.8 VDC, is fed through normally closed contacts of relay K2. This voltage also provides power for the protective circuit illustrated. The voltage appears across R1 and R2, 10k trimpots, the wipers of which are set to exactly midrange, measuring a nominal +6.9 VDC. As the station DC varies between +11.2 and +15 volts, the voltage at the wipers will vary from +5.6 to +7.5 VDC. Zener diode D2 controls the high voltage limit of +15 VDC. R5 and zener diode D4 controls the low voltage limit of +11.2 VDC.

High voltage limit control

A voltage is fed from the wiper of R1 directly to the base of Q1, which is held cut off by the 7.5 volt zener diode D2 from the emitter to ground. Thus, relay K1 is not energized, and its normally open contacts prevent relay K2 from being energized, thus allowing station DC current to flow through K2's normally closed contacts to the station equipment. However, should the station DC voltage rise to or above +15 volts, the voltage at the base of Q1 also rises to or above +7.5 volts, causing Q1 to go into conduction, energizing K1, its collector load, whose normally open contacts close, energizing K2, whose normally closed contacts open, removing the voltage from the station equipment. While the station DC voltage is between normal limits, the green LED D6

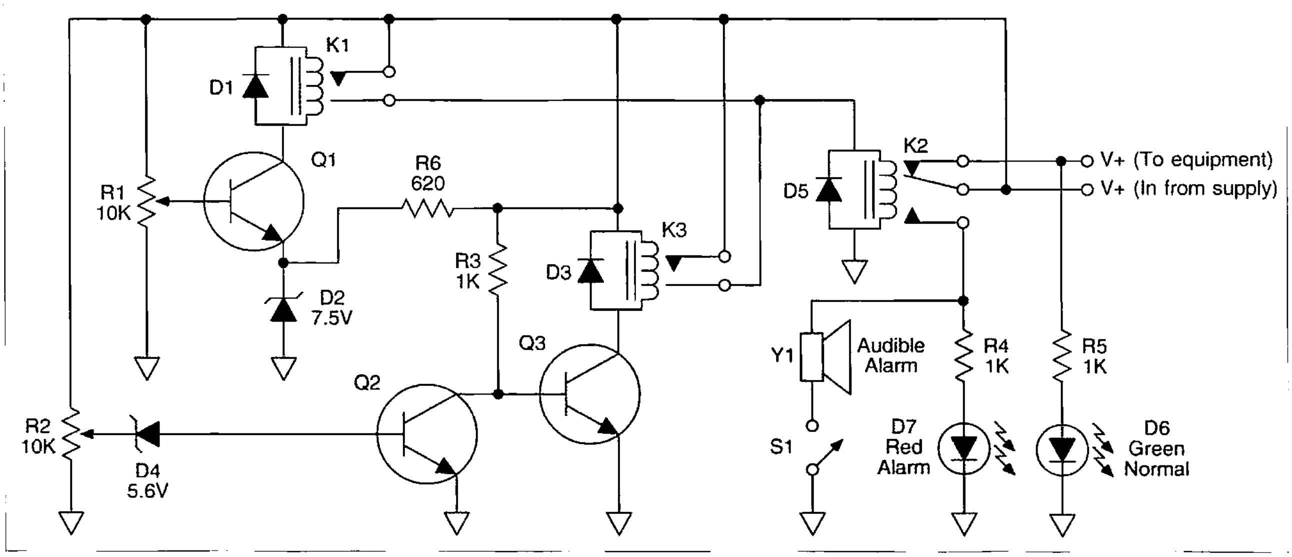

Fig. 1. Automatic Voltage Controller

will be illuminated, being powered through normally closed contacts of relay K2. When the voltage exceeds the high limit of +15 volts as described above, and relay K2 is energized, it removes voltage from the station equipment, the green LED D6, and applies power to red LED D7, and the audible bell or piezo alert, Y1, thus warning the operator of a power malfunction.

Low voltage limit control

A voltage is applied from the wiper of R2 to the cathode of zener diode D4 which conducts, causing Q2 to saturate. The collector of Q2 is connected directly to the base of Q3, which is cut off. Relay K3 is the collector load for Q3, and thus is not energized. Should the voltage fall to or below +11.2 VDC, zener diode D4 ceases to conduct, cutting off Q2 which causes Q3 to conduct, energizing K3. K3 applies operating voltage through its now closed, normally open, contacts to the coil of relay K2, which operates, opening its normally closed contacts, removing voltage from D6, the station equipment, and applying power to red LED D7, and the audible alert.

As described above, while station voltage is within the normal range, the green LED D6 remains illuminated. However, when the voltage falls outside the limits and relay K2 removes power from the station equipment and green LED D6, the normally open contacts of K2 apply power to red LED D7 and the optional audible alarm. Capacitor C1 damps relay chatter when the supply voltage is at either limit.

Construction

This instrument should be constructed in a metal or plastic case, with the LEDs on the panel where they will be easily seen by the operator. The optional piezo alert or 12-volt bell can be placed anywhere convenient. The toggle switch shown in **Fig. 1** should be included if an audible alarm is used, to cut it off until repairs can be made.

Relay K1 (high voltage detector) is actually a SPDT 6-volt relay with a 220-ohm coil, with only the normally open contacts used. Just about any 6-volt relay could be used, but I recommend this one for its characteristics and price. (All Electronics, PO Box 567, Van Nuys CA 91408-0567. Cat. No. RSD-6V. $1.00.) It is rated for 4.3 to 14 VDC, and where I used it in the circuit, the 4.3-V pull-in is important because of its rapidly operating to energize K2 and removing over-voltage.

Relay K2 (main power cut-off) is a 12 volt relay, and SPDT is required. The contact rating will be governed by the maximum current your transceiver draws from its power source. Of course, double-, triple-, or quadruple-pole relays can be used by strapping the contacts together to increase current carrying capacity.

Relay K3 (low voltage detector) has very little work to do, and can be any small 12-volt SPST N.O. relay, or an SPDT using only the normally open contacts. Any of the transistors listed in the parts list can be used. All of these will tolerate up to 6 volts between base and emitter, and a couple are rated for 7 volts.

Internal wiring can be any small hookup wire. Only the leads from your power supply to K2, and the lead from K2 to your station equipment must be commensurate with the current they carry, and the round-trip distance they traverse. The lead to station ground carries very little current. Check all wiring and connections against the schematic. Be certain!

Calibration

Adjust R1 and R5 to about the center of their rotation limits. Apply a DC voltage variable between at least 11.2 and 15 VDC between the top of R1 and ground. Set this voltage to 13.8 VDC. The green LED should illuminate. If it does not, adjust R1 wiper towards ground, and/or R5 wiper towards the positive end. When the green LED is illuminated, follow the directions below to set the desired voltage limits.

- **High Voltage Limit**

Set the variable DC voltage to 15 VDC, or the voltage you choose as high voltage limit. Use a DMM if at all possible for the greatest accuracy. Adjust R1 until the green LED goes out and the red LED illuminates. Set this point accurately to where the red LED just illuminates.

- **Low Voltage Limit**

Set the variable DC voltage source to 11.2 VDC or whatever voltage you choose as your low voltage limit. If the green LED is illuminated, adjust R5 until it just goes out and the red LED illuminates. If the red LED is illuminated, adjust R5 until it goes out, then carefully adjust R5 until the red LED illuminates.

Operation

Operation is entirely automatic, with automatic reset. Adjustments, other than the initial calibration described above, are neither necessary nor possible. This is as idiot-proof as it was possible to design it.

Conclusion

This is a junk box project for most hams, and whatever isn't in the junk box can usually be found at hamfests and Radio Shack™, or from other hams and the many mail-order parts suppliers. A piece of perfboard or a small universal board such as the Radio Shack 276-150 can be used to mount the small parts, including K1 and K3, most likely. But mount it in a metal or plastic enclosure to make certain nothing metallic can fall across any relay contacts.

With this tireless "robot" guarding your expensive solid-state equipment from dangerous and expensive voltage excursions, you are also protecting your wallet from unnecessary and easily avoidable expenditures.

Parts List

C1	25µF 50V electrolytic
D1, D3, D5	IN914, IN4148
D2	7.5V zener
D4	5.6V zener
D6	Green LED
D7	Red LED
K1	6V SPST N.O. 220Ω coil (see text)
K2	12V SPDT, heavy contacts (see text)
K3	12V SPST N.O. relay
Q1, Q2, Q3	NPN 2N2102, 2N2218A, 2N2219A, 2N3904, 2N4401, 2N5320 (see text)
R1, R2	10 KΩ trimpot
R3, R4	1KΩ 1/4W 5%
R5	620Ω, 1/4 W, 5%
S1	SPST toggle or slide switch (optional)
Y1	Piezo alert, 12V bell, etc. (optional)

Receiver RF Preamp

There is a way to improve that old receiver's performance.

Roland Burgan KB8XI
RR 1, Box 43
Hancock MI 49930

Have you ever wished that you could improve the performance of that older receiver you have sitting on the shelf, but couldn't find an easy way to do it? Over the years, many of us have looked into various ways of improving vintage receiver performance, but improving one aspect often came at the expense of introducing other problems. And as solid-state devices came along, we discovered that low voltage DC wasn't generally available in the tube-type equipment, often putting the final damper on the project.

But there is a way to improve performance. The circuit described here is simple, small, and can easily be accommodated in most receivers. It will provide 30 dB of broadband RF gain to the receiver's front end, at extremely low internal noise figures. The parts are readily available, and it can be built for less than $10.

The circuit

The RF broadband preamplifier (**Fig. 1a**) makes use of an NPN VHF transistor, NTE123, as an untuned broadband (0.5 MHz to 30 MHz) RF amplifier. Input impedance is 50 ohms, allowing usage for all receiver inputs, and the unit has a 600 ohm output to match virtually all RF input circuits. The preamp delivers 30 dB of gain at 10 MHz, with a noise factor below 1 dB.

Power for the preamp may be obtained from a variety of sources. The assembly requires from 9 to 14 VDC and draws 8 mA of current. This makes it ideal for use in battery-operated portable equipment. Early tube-type receivers used filament voltages of 6.3 and 12.6 VAC, but had no low voltage DC power supplies. **Figs. 1b** and **1c** show how to "borrow" a little of the filament voltage, which is rectified and regulated to provide filtered 12 VDC for the preamp. In the 6.3 VAC version, diodes D2 and D3 act as a simple voltage doubler to step the input voltage up to approximately 15 VDC.

While the 220 µF caps used for the voltage doubler are sufficient for the load presented by this preamp, they will not provide the +15 VDC to the input of the regulator at more than about a 25 mA load. If other circuits will be used with these DC power sources, then the 220 µF caps should be increased accordingly. (2200 µF will provide about 65 mA regulated output).

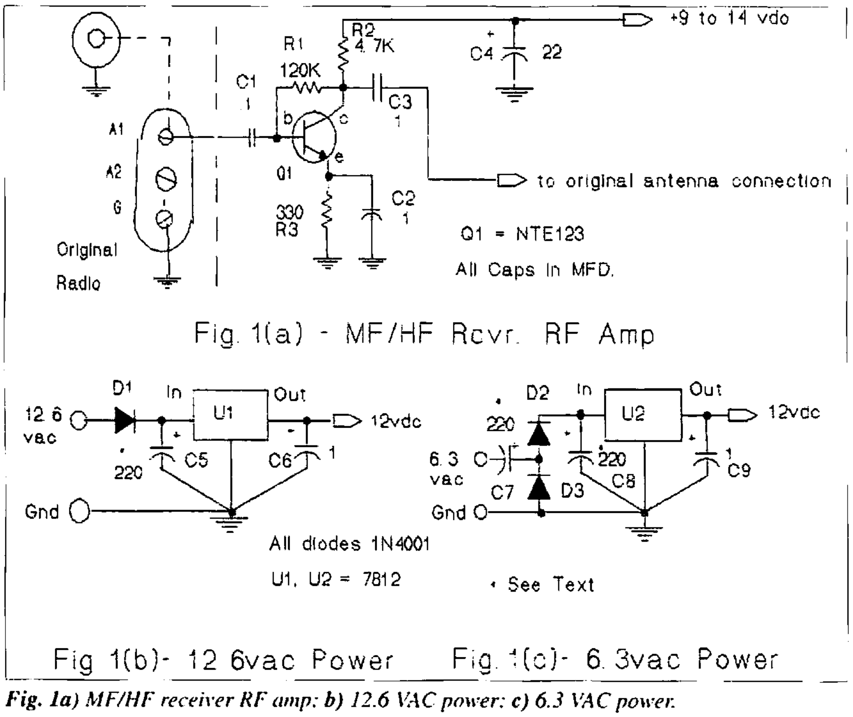

Fig. 1a) MF/HF receiver RF amp; b) 12.6 VAC power; c) 6.3 VAC power.

Construction

In my installations, I make up two separate PCBs, one for the preamp, and another for the power circuit, to make better use of internal mounting space. The preamp should be mounted as close to the antenna input as feasible. Construction is not critical, and point-to-point construction may be used. Most preamp mountings will require nothing more than a right angle clip, while the power boards can usually be mounted to a back panel with standoffs. All other parts are standard values, but electrolytic caps should be rated at 35W VDC. Please note that the collector of Q1 is also internally connected to the metal external case.

The author may be contacted by mail (enclose an SASE) at the address above, or via E-mail at: rburgan@grfn.org .

Parts List

R1	120k, 1/8W	Mouser, Radio Shack
R2	4.7k, 1/8W	Mouser, Radio Shack
R3	330k, 1/8W	Mouser, Radio Shack
C1, C2, C3	0.1 µF, 50V	Mouser, Radio Shack
C4	22 µF, 35V	Mouser, Radio Shack
C5, C7, C8	220 µF, 35V	Mouser, Radio Shack
C6, C9	1 µF, 35V	Mouser, Radio Shack
Q1	NTE123 (NPN transistor)	Mouser
U1, U2	7812 (1.5A Pos. 12V reg.)	Mouser, Radio Shack

Dayton HamVention '96

The Dayton HamVention is an event I look forward to all year round. This year I was particularly excited about moderating the Instructors' Forum on Friday afternoon. I had put together an impressive group of talented speakers, and I couldn't wait to meet with them. Besides being experts in their own areas, they are all high on my list of great folks I look forward to seeing.

At this yearly forum we attempt to present a variety of ideas, suggestions, and proven techniques to share with other teachers. Both classroom teachers and instructors in licensing classes can really get some good practical ideas at this workshop.

First I introduced Rosalie White WA1STO, head of the Educational Activities Department at the ARRL. She presented an overview of the package of materials that the League has to offer the teacher. I've personally used so many of the great lessons, charts, guides, etc., from this package of materials that I can vouch for their excellence. There is a wealth of information about amateur radio out there. The ARRL Education Department is a good place to begin gathering your data. Ask for Rosalie or anyone else in her department for assistance in getting a radio program started.

Next to speak was Ellie Van Winkle NØQCX, from Boulder, Colorado. Ellie is a retired kindergarten teacher whom I met four years ago at Dayton. We bonded instantly, and have had great success working together for the Dayton Youth Forum. She and her husband, Rip NVØM, created the BARC Jr. club for youngsters interested in ham radio. This group is one of the most successful youth groups in the country.

"Ellie and Al Severson WB2PRZ spoke about how to have successful fund-raisers."

Ellie and Al Severson WB2PRZ spoke about how to have successful fund-raisers, an important issue to any growing club that needs to support its members in different activities. Since BARC Jr. sent four children to participate in my Youth Forum this year at Dayton, they really had to get well organized in their fund-raising efforts. Besides having swap tables, raffling a donated bicycle, and soliciting donations, BARC Jr. also received a donation of frequent flyer miles, which helped defray the airfare. It was apparent to all in attendance that the dedication of the parent club, BARC, is a major factor in the success of the children's group.

Bob Heil K9EID, one of my favorite professor-speakers, wowed the audience with his antenna theory demonstrations. He used two microphones to demonstrate phasing, along with a dramatic flashlight-phasing demo. Bob is the recipient of many awards including the 1982 "Ham of The Year" award and the Pioneer Award for his groundbreaking work as a sound systems developer and engineer for such major groups as The Who, Peter Frampton, The Doobie Brothers, and many more.

Bob is so enthusiastic about the role of teachers in amateur radio, it's always a pleasure to have him as a guest speaker.

Bill Pasternak WA6ITF, who is the author of hundreds of technical articles, and was the 1989 "Ham of The Year," spoke about why he created the "Young Ham of The Year" award. He felt it was important to honor youngsters who were actively contributing to the hobby. Bill spoke about the qualifications for nomination and how to get an official entry form. For more details about this contest, contact Bill at 28197 Robins Ave., Saugus CA 91350, or telephone 805-296-7180.

The Instructors' Forum is always informative and fun to attend. Why not plan to attend next year?

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

In "Ham To Ham" in the June 1996 issue of *73*, I mentioned a practical use for those small laser pointer pens—using one to help locate a soldering pad on the foil side of a circuit board by shining its beam over the part to be unsoldered on the component side. I asked for other interesting uses, and I received this from **Harry SMØVPO** in Upplands, Sweden: "Those little laser pointers are about the easiest way that I know of to catch a fly! That's right, just shine it on the little bugger's head and it can see nothing else but the laser; now you simply pick it up! If you've ever wanted to catch a live fly—without damaging it—for study under a microscope or for macrophotography, this is the best method I've found ... I even have the pictures to prove it!"

Now there's a novel use ... from the land that gave us the zipper!

Well grounded!

Here's an easy "quick modification" to keep in mind the next time you have your ham transceiver—or other accessory piece of gear—apart on your workbench. Check to make sure that the area on the inside of the metal cabinet covers is capable of making good ground contact when the cabinet covers are fastened back into place. It may seem obvious at first, but I've noticed that most ham manufacturers are guilty of "over-spraying" the insides of the cabinets during the cabinet spray-painting process. This over-spray can vary from very light to quite heavy ... depending upon luck, I suppose. At any rate, sanding, scraping, or otherwise cleaning the areas on the cabinet's inside can sometimes increase the RF shielding properties of the enclosure dramatically.

Those areas, especially around the screw holes, should be scraped clean—down to shiny metal—of any paint over-spray in order to assure good RF ground contact when the outside screws are tightened. I like using a small, hand-held "motor-tool" (such as the one made by Dremel) with a conical burr-style grinding bit in it for the job; it makes it fast and accurate.

Remember, what might be a reasonably adequate ground at DC and audio frequencies may not be effective enough at RF frequencies, especially at the VHFs and beyond. A little effort brings a lot of peace of mind.

An unwelcome battery load

Erich Kern of Murrieta, California, wrote:

"It was interesting to me to read your piece on conductive adhesives in the November 1995 'Ham To Ham' column. I, too, have had occasion to encounter the same effect, but with masking tape instead.

"About 20 years ago, I learned quickly that some masking tapes can become semi-conductive after a time, creating unexpected leakage paths. In my case, I was using the masking tape to cover the exposed terminals of spare 9 volt batteries, only to find that the tape eventually became partially conductive—measuring about 20k ohms with the probes spaced 1/2 inch apart across the tape. Needless to say, the 'protective tape' was also discharging my spare 9 volt batteries! It's difficult to say whether the tape adhesive was the culprit (after it dried out to some degree) or if the paper-based masking tape merely picked up moisture from the atmosphere and then became a semiconductor. Whatever the reason, others should be aware that the problem can and does happen under the right (?) conditions."

Moderator's note: In the May 1996 HTH column, I made the suggestion of using Johnson & Johnson's 1/2-inch-wide waterproof First Aid tape on conductive pathways, instead of other tapes that might become hygroscopic or otherwise semiconductive with time. I've been very happy with this product in my own equipment so far. Are there any other tapes that readers have used with long-term success, ones that don't become goopy after a while? Also, I ran into the conductive adhesive pitfall again. This time it was in a computer color monitor that I purchased at a local hamfest. The manufacturer had used an adhesive on some of the components that he didn't want to move during shipping, but, with time, it began to get semiconductive when it hardened. It became noticeable in the horizontal deflection section of the monitor, causing the width of the screen's raster to change unpredictably from time to time. Once I removed the problem adhesive (which had become very hard, brittle and probably hygroscopic), the problem was corrected ... Murphy strikes again! 100% silicone bathtub sealant seems to be best for holding down heavy parts on PC boards: it will last virtually forever and doesn't pick up moisture. Just take care to let it cure for the time recommended by the manufacturer before applying power to the circuit, and don't use it directly on the copper foil itself because of the acidic chemicals that it contains.

Ridin' the rails

I ran across a product that model railroaders often use, but which may also have practical application within ham radio. It's called Rail-Zip™ and is made by Pacer Technology, 9420 Santa Anita Avenue, Rancho Cucamonga CA 91730-6117 (1-800-538-3091). It's a multi-purpose liquid product that cleans, lubricates, conditions, and protects metal surfaces from mineral scale and rust.

I've used it on a small Z-gauge layout that I have, and it seems to work. Model railroad track has the tendency to become a poor electrical conductor due to the "micro-sparking" (my term) that goes on between the engine's pick-up wheels and the track every time it's run. Rail-Zip is supposed to penetrate the corrosion that's behind this tendency, and restore proper conductivity. It's also claimed to help prevent new corrosion, which will minimize future sparking for 8 to 12 weeks. Sound like it might be useful for connectors and switch contacts in our ham gear?

I wrote to Pacer, out of curiosity, and this is a paraphrased summary of their reply:

"Rail-Zip penetrates to produce a clean metal surface, leaving an organic barrier that prevents further scale from forming. It's formulated for use on all metallic surfaces, and is pH stabilized, water soluble, and safe around plastics. An oxygen scavenger works as a corrosion inhibitor to prevent cavitation, erosion, and pitting on metallic surfaces. It's completely organic, biodegradable, environmentally safe, and non-toxic to handle. Though not tested on connectors and switches used in amateur radio equipment, we feel that it will restore the electrical conductivity of them, and provide a corrosion barrier as well."

It might be worth keeping in mind, especially for outdoor antenna connections where corrosion can often be a big factor in intermittence: Rail-Zip is available at hobby stores and via mail-order from catalogs that cater to the model rail hobby.

The right packet path

From William Thim N1QVQ: "Having been involved in VHF packet for a couple of years now, I've become conscious of a lot of hams who might be newer to that mode, questioning on 2 meter packet and voice what's available in the way of node hopping, BBSs, HF gateways, etc. in our area. I usually jump in and try to help with tales of my own experiences, but if it's on a repeater, more often than not the station is mobile, and unable to write down the information that I might have to pass on.

"In view of that limitation, I've taken to placing special information messages on my home PBBS, addressed to ALL, but only within my home district. A short description of the subject also helps, such as NODE HOPPING or perhaps HF GATEWAYS. I know that a significant number have benefited from these messages, and I've benefited myself with additional information coming back to me

from others who know of paths that I wasn't aware of. It pays to share!"

Freebie sealant!

From Bob Boehm N8EXF: "Here's a readily available source of sealing compound for those outdoor coaxial cable connectors or weather-exposed antenna relay control boxes ... and it's free for the asking. It's the windshield edge sealant used by the aftermarket automobile windshield replacement guys that you see in people's driveways, replacing damaged windshields right on location. I was able to acquire a nearly unlimited supply of this sealant simply by asking one of the repairmen for any 'tail-end' rolls that he had lying around: rolls that usually just end up in the dumpster.

"Since locating this 'free' source, I've been using it exclusively for the past six years on all of my outdoor coax connections. While it isn't 'flat' in its acquired form, it's easily reworked, with just the fingers, to make an effective sealant for even the tightest of nooks and crannies. If you're worried about any adverse chemical reactions between the sealant and the metal on the connectors, simply wrap the connector first with one layer of electrical tape before applying the auto window sealant. It also makes for a 'cleaner' removal should you ever want to open the sealed connection for some reason. You can't beat the price, and it gives you a chance to tell a prospective newcomer (the windshield repairman) about the wonders of the world of ham radio!"

Broaden your scope!

From Michael Fratus: "Even an inexpensive oscilloscope can be made to act more like one of the very expensive ones with a little ingenuity! Many of the 'big dollar' scopes offer on-screen voltage and frequency measurement as part of their selling points, but you can have nearly the same features for a lot less money.

"By using a couple of inexpensive BNC 'T' connectors on the scope's input, you can easily hook up both your DVM and your external frequency counter, so that you'll have a voltage and frequency reading—along with the scope presentation—wherever you place your scope probe during troubleshooting. It's a good deal easier than trying to read DC voltages by the amount of bounce on the scope trace, and frequency by converting microseconds into megahertz! And it surely beats paying $8,000 for a later-model scope!"

Parts hunting made easy

From Peter Albright AA2AD: "One of the greatest challenges in any servicing endeavor (ham radio equipment included) is in identifying parts and finding serviceable replacements for defective ones. The manufacturer's technical service manual (of course) should be consulted first, if available, but what if you don't have access to one? My favorite semiconductor cross-reference is the EGC Master Replacement Guide, which is just chock-full of semiconductor data in almost 'painful' detail! It's less than $10 if purchased new, but it can sometimes be acquired free from service shops (when a new one comes out) or from some parts dealers, if you're a high enough dollar customer. ECG is a division of North American Philips Corporation, and you can contact them at: Philips ECG, 1025 Westminster Drive, Williamsport PA 17701. Incidentally, the ECG parts numbering system has also been adopted by several other 'generic' parts suppliers.

"The SK semiconductor parts series (from the former RCA Corporation) is also often used or quoted in replacement data as something of a standard, very much like ECG. The SK Replacement Cross-Reference is now available from: Thompson Consumer Electronics, 2000 Clements Bridge Road, Deptford NJ 09096-2088.

"Radio Shack also publishes a semiconductor replacement guide. It's available for sale or in-store use at most Radio Shack retail outlets. It usually only details parts actually being currently sold by RS stores, but it also contains a reasonably complete general cross-reference section.

"Because of their widespread presence, I'll often frequent my area Radio Shack stores first, when looking for replacement parts. Their parts are generally name-brands, simply repackaged in single or double lot bubble packs, but you can't beat the convenience and speed of obtaining a replacement in a number of cases. If they don't have what I need, however, I'll turn to the mail-order houses. One of my personal favorites is MCM Electronics, 650 Congress Park Drive, Centerville OH 45459-4072 (1-800-543-4330). They offer a good selection of parts, power supplies, tools, test equipment, computer accessories, etc. in their free catalog.

"Other suppliers that I've used include: American Design Components, 400 County Avenue, Secaucus NJ 07094 (1-800-776-3700); Black Box Corporation, P.O. Box 12800, Pittsburgh PA 152421 (1-412-746-5500); Fox International, 23600 Aurora Road, Bedford Heights OH 44146 (1-800-321-6993); Jameco Electronics, 1355 Shoreway Road, Belmont CA 94002-4100 (1-800-831-4242); Jensen Tools, 7815 S. 46th Street, Phoenix AZ 85044-5399 (1-800-426-1194). Tucker Electronics, 1717 Reserve Street, Garland TX 75042 (1-800-527-4642 Nationwide, or 1-800-749-4642 within Texas) carries a good line of test equipment, ham gear, computers, and accessories.

"The above listing is by no means complete, but I've personally found these suppliers to be reliable, often having the correct parts that I've needed in my repair work."

Moderator's note: In addition to the suppliers Pete mentioned, Digi-Key Corporation, 701 Brooks Avenue South, P.O. Box 677, Thief River Falls MN 56701-0677 (1-800-344-4539) has a thick (free) catalog of parts and semiconductor components for the asking. I've had very good experiences over the years ordering from them and I love the name of that town!

A pin-up beauty!

From Klaus Spies WB9YBM: "Often, when designing a new home-brew item, or if repairing a factory-made piece of equipment, I've done some head-scratching trying to remember the standard resistor values available. But here's a chart that makes it much easier, so I'd like to share it with my fellow builders. See **Table 1.** It applies to both resistor and capacitor standards.

"All of these values are then followed by the appropriate multiplier, for example: 4.7 47 470 4.7K 47 K 470 K 4.7 Meg.

"When 10% resistors were the norm, every other value was skipped, beginning with 1.1, then 1.3, 1.6, 2.0, 2.4, etc.

"Today, with 5% resistors as the norm, the values shown in the chart are commonly available from the larger suppliers.

"For those who might be curious as to how these values were arrived at, this is the mathematical explanation:

"(1.0 + 5%) = 1.05, and (1.1-5%) = 1.045.

This implies that if one value of resistor is at the high end of its tolerance, it will overlap with the next higher standard value. This allows a person to pick almost any value required for a particular project, even if the tolerances are demanding, presuming that you have enough stock in the various values to choose from.

"By the way, experience has shown me that today a new, unstressed resistor is seldom at the

Standard R/C Value Chart—
use multipliers as required:

1.0	1.1	1.2	1.3	1.5	1.6	1.8	2.0	2.2	2.4	2.7
3.0	3.3	3.6	3.9	4.3	4.7	5.1	5.6	6.2	6.8	7.5
8.2	9.1	10.0								

Table 1.

extreme of its tolerance range. In fact, modern metal-film resistors can be almost dead-on many times value-wise."

Moderator's note: I've pinned up Klaus' chart over my workbench—how about you?

Etceteras

If you're looking for a Heathkit part at some point in the future, you can try calling Heath's parts order desk at 616-925-5899. Heath has sold some of its parts stock to Spectrum Electronics, so if Heath itself doesn't have it, then try calling Spectrum at 616-742-0613. This isn't an ad for either vendor: it's simply intended as potentially needed information for fellow hams.

Tape tips

From Steve Thacker KB5VCA: "In my professional career as a superintendent for a mechanical and electrical contractor, I've come upon a number of types of tape for use in outdoor electrical situations, some of which might be of help to my fellow hams. Everyone has probably heard of, and perhaps used, Scotch™ No. 33 electrical tape: it has particularly superior stretching ability in cold weather, won't harm copper or aluminum, and can be sealed even tighter with Scotch 1602 spray sealer. 3M also makes a nice 'splicing' tape: it's a two-sided tape—one side is soft (like a good rubber tape) and the other is much harder and more weather-resistant. It 'cures' over a short period of time into an effective outdoor splice, the harder outside layer taking the brunt of the elements. Other manufacturers may make similar products: the 3M numbers are simply to give readers a point of reference from which they can start. Most electrical supply houses, and now some of the larger home centers, carry these products for shopping ease."

Cheap power zener replacements

From Richard Measures AG6K: "Most HF linear amplifiers have a relatively high-power zener diode in the cathode circuit of their output tube (or tubes) for biasing them into the linear portion of their operating curve and for providing a stable, fixed cathode bias. This zener diode is prone to zapping out, particularly if a high-power VHF parasitic oscillation should occur, because of the large grid-current pulse that always accompanies a VHF parasitic arc-over. It's a costly and sometimes difficult-to-find component to replace. A better solution lies in the use of ordinary silicon rectifier diodes; here's why: 1.) Zener diodes are not adjustable; 2.) Zeners are relatively sensitive to high-current pulses; 3.) And, as mentioned, higher-power zeners are expensive and harder to find.

"Fortunately, the substitution of ordinary silicon diodes addresses all of these objections. Since ordinary power silicon diodes have a stable forward voltage drop of about eight-tenths of a volt DC (0.8 volts) across each diode, a series string of these relatively inexpensive diodes can be cascaded—to make up a stable cathode-bias regulator, for virtually any voltage required. Additionally, this 0.8 volt step-range gives you some desirable leeway in customizing a replacement circuit for your own particular linear amp. Now, by simply adding or subtracting diodes from the string, you can adjust the zero-signal anode current for your particular amp and tube combination parameters (guided by what the tube manufacturer recommends as the ideal idling current for that particular tube type). That's something you can't do using a fixed-voltage-power zener. Here's a quick example:

"Seven silicon diodes will provide a stable cathode bias of 5.6 volts (7 times .8 volts), 8 diodes would give 6.4 volts, 9 would yield 7.2 volts, and 10 silicon diodes would provide an even 8 volts.

"You can make up a small perf board layout for the diodes, say 10 diodes in all, then, with just a wire jumper, bridge out the ones that aren't needed, in order to arrive at the target anode-current 'idle' figure that you're seeking. If a new tube (or set of tubes) later on changes this figure significantly, you can readjust the idle current by simply moving the jumper.

"And don't forget, we're utilizing the 'forward voltage drop' of the silicon diodes—as opposed to the 'reverse voltage drop' in the case of the zener we replaced—so that the banded cathode end of this new stack will go to the point where the anode end went before, that is, just exactly opposite of the way the zener was wired into the circuit. You can use virtually any PIV rating for the diodes, since the voltage at the cathode is very low. The current rating of each diode in the string, however, should safely exceed the maximum expected cathode current, up to 3 amps maximum. Here's a final advantage: If you should happen to be the unfortunate victim of another high-energy parasitic pulse, it's a relatively simple matter to replace the diode or diodes that may have suffered the brunt of it ... and again, with a whole lot less cash outlay!"

We end this month's column after another of Rich's worthwhile ideas. Watch for many more in the months to come. If your idea isn't in here, why not? Everyone has run into interesting problems and found their own unique solutions to those problems. If you'd like to share yours with other readers, send them to me at the address above and I'll let you know promptly whether it will be used or not, and roughly when. The column is prepared a few months before the time that you read it because of magazine layout and printing considerations, so don't expect to see it next month, but chances are good that it will be used in a near-future issue. So click on the word processor program icon in your computer, and write a few lines about your favorite tip, technique or shortcut ... don't forget!

Our sincere thanks to this month's contributors:

Internet: clhough@aol.com

Adjuncts and other paraphernalia

This month's topic is adjuncts and paraphernalia that can be added to your equipment, making microwave operation easier with Wide Band FM (WBFM). Just having a transmitter and receiver rolled into a single neat package doesn't guarantee you'll make successful contacts. A few other ingredients are necessary, especially for those with the simplest equipment. By "simplest equipment" I mean the burglar alarm type of Gunn diode oscillator and detector arrangements, not the highly coveted Microwave Associates varactor-tuned Gunnplexers™.

The simple Gunn diode cavity devices are frequency dependent and must be adjusted to a set frequency in the amateur portion of the 10 GHz band. The units are aligned with an absorption type wavemeter before operation. Once frequency is set they have a narrow window over which voltage can be varied on the Gunn oscillator to make fine frequency adjustments. These frequency adjustments can move the basic oscillator over a 3 or so MHz frequency range at best. Primary accuracy is essential and must be set properly with the wavemeter type of frequency meter.

The varactor-controlled units like the Microwave Associates' Gunnplexers are premium units and offer frequency agility over a 60 to 80 MHz frequency range. If one end of your circuit has one of these units, other hams will find you, even if you are off frequency, and still make contact. The biggest problem with the burglar alarm type of Gunn oscillator is that you have to monitor the voltage tune pot for frequency disparities. If you like to tinker, read on; if you want to have an excellent unit, purchase the M/A unit. You decide what's best for *you*.

A nice addition to the operating unit is a wavemeter, coupled to an RF power meter amplifier, to increase the sensitivity of the wavemeter. Another test fixture is the twiddle tone generator. This device puts a distinctive tone on your transmitter through the audio amplifier modulator circuit, allowing weak signals a little better detection ratio when you are hunting for them in the noise. Other useful items are some good grid-square map locations of other stations, an ordinary compass, and other similar aids to help you aim a microwave signal towards a distant station accurately.

Each time you eliminate or reduce uncertainty in the microwave arena, your chances for a successful contact improve. The list of basic uncertainty items includes Gunn frequency accuracy, 30 or 88 MHz IF offset properly set, system sensitivity, and accurate compass bearings to the distant station. These are the main wobbles in the basic system and need to be addressed using some test equipment, plain old experimentation, and technical improvements.

The Gunn diode oscillator frequency can be set with a cavity wavemeter covering the 10 GHz frequency ranges. Rotate the drum dial, which changes the internal size of the cavity chamber (coupled to a section of waveguide). At various increments, the drum's outer surface is calibrated in frequency, reflecting the different cavity sizes as it's rotated. The cavity is a very high "Q" circuit and samples RF power going through the cavity's waveguide section. You will need some form of RF detector to observe relative RF power. Then notice the RF power level, spin the cavity, and when a slight dip is observed, this is your frequency. The cavity is absorbing some power when it is adjusted to your frequency; this mode is referred to as a "suck out" or "absorption" type of wavemeter.

The dip in power is sharp, and it's a slight dip, so adjust the wavemeter slowly for best accuracy. The meter amplifier is coupled to a detector on the waveguide output, allowing greater sensitivity to sample measurements being taken rather than direct connections to your system. A small horn antenna should be used on the input to the wavemeter, completing the package for the frequency meter and its wavemeter. See **Fig. 1** for the block diagram of how to connect these component parts for the monitor antenna, wavemeter/detector, and meter amplifier.

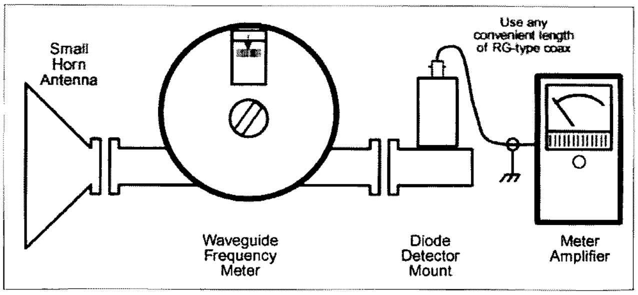

Fig. 1. Waveguide test antenna, wavemeter and meter amplifier. This setup is used to determine RF frequency, using a small horn antenna and a variable commercial waveguide frequency meter. RF is sampled with a detector and displayed on an amplified meter for sensitive meter indications.

This one simple meter amplifier, coupled to a commercial absorption wavemeter, is essential in locating and telling you what frequency you are operating on. The wavemeter coupled with a meter amplifier, affording higher sensitivity, allows you to make frequency measurements close to your antenna vs. a direct connection.

The circuit for this amplifier is a single voltage supply (9-volt) portable radio battery powering a single CA-3130 op-amp amplifier. Do not use a substitute for

***Photo A.** WB6IGP operating 10 GHz WBFM on top of Mt. Soledad in San Diego. The spike on top of the dish is a 2 meter ground plane antenna for 10 GHz contact coordination.*

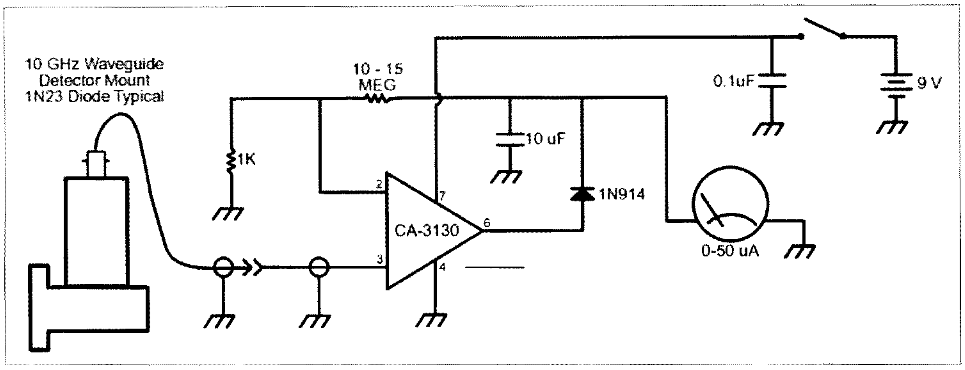

Fig. 2. Schematic diagram for the wavemeter amplifier that is connected to the microwave waveguide detector. This circuit operates on a single 9-volt transistor radio battery for simplicity.

the CA-3130, as others will not work in this circuit. The CA-3130 is made to work with a single supply voltage and ground, unlike other op amps. See **Fig. 2** for the necessary schematic diagram.

> ***"It's still a sensitivity game, and this little tool is so simple to build that all you need is a waveguide detector mount, to which a small TTL 5-volt oscillator is capacitor-coupled."***

System sensitivity improvements

A simple circuit using a simple Gunn transceiver is a circuit called the "Boomerang." What it does is essentially just what its name implies; weak but detectable signals are reflected back to the source. It is not a frequency calibrator for microwave as its operation is dependent on whatever frequency IF system you use, but it does receive your transmit RF and mix it with a fixed crystal oscillator equal in frequency to your system's IF frequency. It then re-radiates this new mix product which is detectable in your receiver. This signal can be used to test system sensitivity by moving the boomerang farther away from your transceiver as system sensitivity increases.

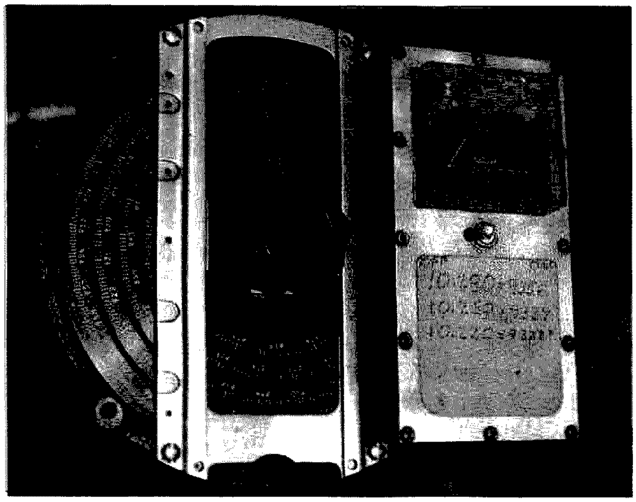

***Photo B.** Surplus waveguide frequency wavemeter with amplifier and meter indicator attached. The unit had calibration readings noted for 10.220, 10.250, and 10.280 GHz. It was very useful when using simple Solfan or burglar alarm type Gunn oscillators for WBFM.*

Add a dish or other directional antenna to your system, and the same Boomerang can be used to adjust antenna feeds for best gain. It also can be used to test angles of your dish or other antennas. It's still a sensitivity game, and this little tool is so simple to build that all you need is a waveguide detector mount, to which a small TTL 5-volt oscillator is capacitor-coupled. Any oscillator operating at your IF frequency will work here, be it a ready-to-go TTL type or a home-brewed device. In either case, it is coupled to the detector mount and antenna attached to the Boomerang.

If your IF system is 30 MHz, use a 30 MHz crystal and set it to the same frequency at which your 30 MHz IF is set. If you are using the 88 MHz FM radio as an IF amplifier, select a crystal to match the IF frequency you select (i.e. 88.123 MHz). That's all there is to it. Power in the oscillator is not important—just a single transistor oscillator circuit will do. See **Fig. 3** for circuit information.

Grid square program

Our microwave group has a grid square program written in BASIC that should run on most any PC. It will give you compass direction to and from distant stations, once data with grid square or latitude and longitude information is input. The program is a bonanza, eliminating guesswork with map coordinates converted to grid squares, which is often needed for contest operation. The program runs in the Chevy manual mode. For the latest input to this program for Caddy drivers, GPS (Global Positioning Satellites) are used; the exact-position data is loaded into the computer's RS-232 input port and loaded into a modified BASIC program. Additionally, a very small interface terminal has been built by Jay Goldberg, to take the data directly from the GPS receiver and display universal time and latitude/longitude data to a small 20-character plasma display. This display could be mounted on the dash of a car for portable pinpoint accuracy on location.

Well, there you have most of the insights into microwave operation, and some options on how to set up a small inexpensive station. These trails, laid out for you, were exactly the same beginning steps that many of us took, myself included, in years past. Yes, we still have our WBFM equipment, but we have grown into much more complex and costly equipment in the pursuit for better devices and systems. I strongly urge you to try WBFM as a beginning test vehicle; it's inexpensive and will give you some experience in the microwave realm.

10 GHz—the next generation

When you're ready for improved circuitry, high stability systems, GaAsFET amplifiers, and synthesizer frequency control to 100 Hz at 10 GHz, let me know. We have kits available, derived from commercial material, that require modification of a microstripline PC board. After modification, these units assemble into a very high-quality SSB linear system with 1 watt of output power and a receive noise figure of 1.5 dB on 10 GHz for a full-figured configuration. The basic system is contained on a single PC board (4-1/2" x 5-1/2" x 1/2" high). All circuitry is on the board, including mixers for 10 GHz. Prices start at $100 for a basic kit, plus shipping and CA tax (for CA residents only), and are available from the author, me, at the address above.

Other microwave systems have been constructed using components that were found in the

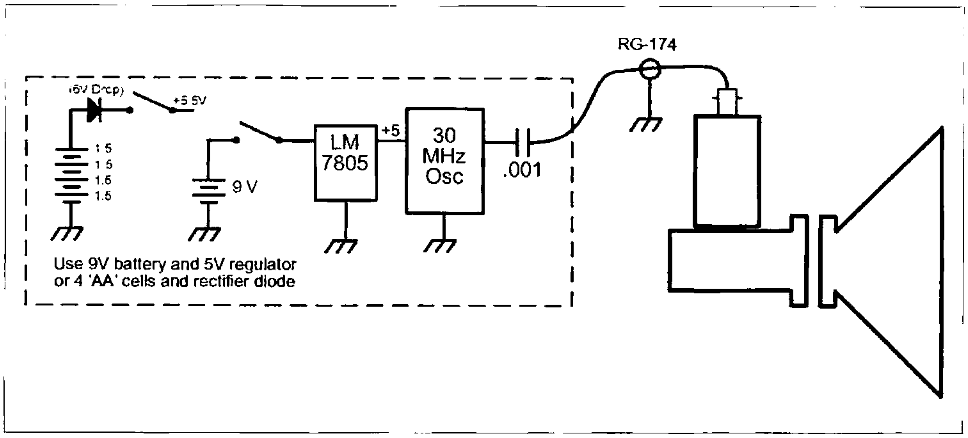

Fig. 3. The Boomerang, or microwave reflection antenna, is a slick test accessory that helps you make relative tests to improve your system's sensitivity. It can also be used to test feed position and microwave dish aiming characteristics. The essential component is the 30 MHz TTL oscillator and a waveguide detector mount. If other IF frequencies are being used besides 30 MHz, change the crystal frequency accordingly.

surplus market. It's amazing what can be lashed together to make a microwave converter. As an example, the above kit for 10 GHz sounds quite hi-tech. Well, for frequencies lower than 10 GHz, the gizmos needed are not as fancy or as expensive. As frequency decreases further, more and more components can be brought into play to construct a simple microwave converter.

What microwave piece parts do you look for when trying to gather material for lower frequency bands? As in any system, you need a mixer—that is a *must*. After that, you need a local oscillator to convert your IF, which could be a low-power handie-talkie on 2 meters or 450 MHz. Couple it to an amplifier with a coaxial relay to switch the circuit and you have the basic ingredients needed: mixer, local oscillator, amplifier, and relay switching.

Why venture into other amateur frequencies? In our case it started with a challenge from Kerry N6IZW: Attempt to construct a simple system for the three lower frequency microwave bands. The plan was to try and get something up and running for each of the 2304, 3456, and 5760 MHz frequency bands, one a month, for demonstration at our club/group meeting.

The requirements were not stringent, and might be nothing more than a local oscillator and mixer for each frequency in question. The intent was to promote microwave interest, along with a challenge to see what our group's members were crazy enough to assemble. The challenge was like trying to line up volunteers for a cardboard boat race. Somewhat practical, but all for fun!

If you're wondering how we achieved such a frequency-stable synthesizer, it's the main reference clock (10 MHz accurate to .01 PPM) that locks up the main synthesizer to minimize frequency errors. As I said, new toys and devices are only separated by the cost of the toys—I hesitate to mention cost as a separator between modes of operation and equipment for microwave. WBFM, as you can see, required very simple devices to make it tick. This system, on the other hand, requires an increased level of both technical skill and test equipment to make system modifications and see just what is going on. My workbench includes spectrum analyzers and microwave power meters and signal generators and sweep oscillators accurate to 18 GHz. If you venture into this realm, hopefully there will be some test equipment available to you on an individual or club basis to test your projects.

While all this equipment is not necessary, it gives you a glimpse of the increased test equipment you must have in order to modify microwave stripline circuit elements. You need some basic generators and power meters, along with technical skills, to work with these small microwave circuits—microsurgery is not for everyone and at times it's not for me. I have made my share of big blunders, primarily due to speed vs. eyesight problems with the chip component circuitry. I was able to overcome speed by just going slower and being more careful. As to the eyesight problem, I've corrected that by purchasing a dual eyepiece hood magnifier to back up my reading glasses. It really filled the bill for seeing fine details on the printed circuit boards' chip circuitry that are .050 inch square. Soldering miniature components like this can be quite demanding, trying to make a neat, orderly connection and do a good soldering job at the same time. With the magnifying hood it was not a problem.

So much for this month. Next month, I will report on the San Diego Microwave Group's progress on our quest—our energetic construction program. I will have data on the 2304 and 3456 MHz rigs that were constructed. Do not expect fancy frills or high power: these are for fun. I can't wait to see what rigs are constructed. 73 Chuck WB6IGP clhough@aol.com.

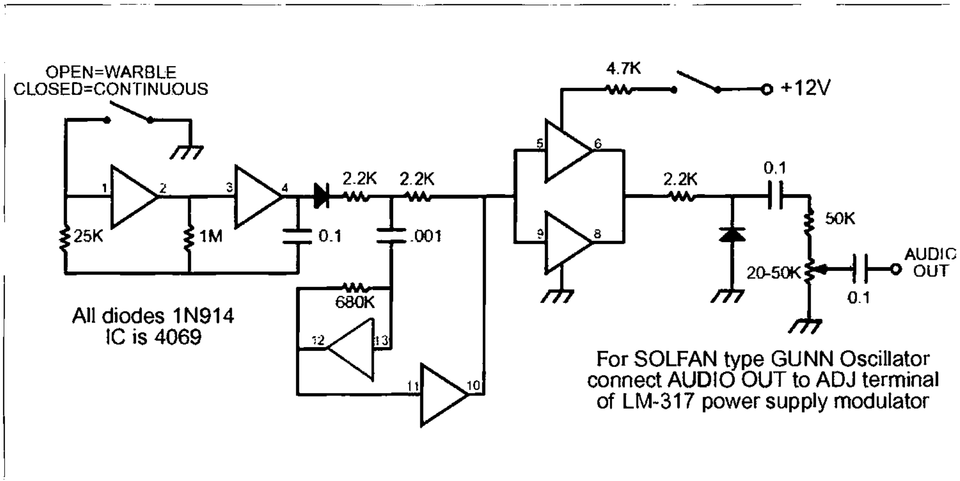

Fig. 4. The schematic of the twiddle tone generator. This unit produces a distinctive tone that skips between two different frequencies, producing a tone pattern, allowing an easier search for new units to communicate with. It's our equivalent of a simple beacon-like tone identification accessory.

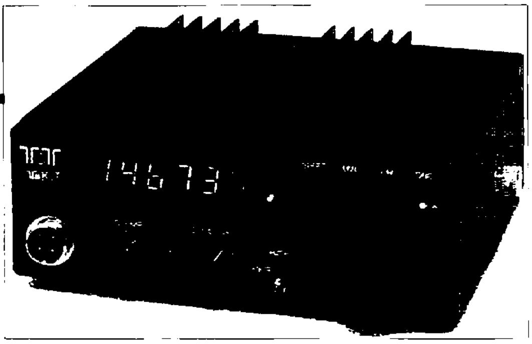
The Ten-Tec 2m Transceiver Kit

Have a ball building this great little $200 rig.



Jeff Gold AC4HF
1751 Dry Creek Road
Cookeville TN 38501

This time I'm really excited! With all the new no-code Techs, the most common ham buy these days is a 2 meter transceiver. Since I have always enjoyed operating radios that I have built myself, the Ten-Tec T-Kit #1220 looked like just the ticket. Besides, while building, I am also learning how the equipment works, so I'm more likely to be able to repair it.

Ten-Tec is filling the void Heathkit left when they quit. They obviously put a lot of work into designing a microprocessor-controlled 2 meter rig that can be assembled, adjusted and maintained by hams with average building and soldering skills.

The rig has front-panel tuning in 5 kHz or 2.5 kHz steps. There is a six-digit sunlight-filtered LED frequency display and 15 programmable memories. There is also provision for five non-standard offsets and a built-in CTCSS tone generator. The transmit-receive switching is done with diodes. The rig uses a standard five-pin DIN packet connector and circuitry. There is a built-in speaker, as well as an external speaker jack. You can switch between two power levels from the front panel. Without the optional 1222 amplifier kit you will get about 1 or 5 watts, and with the amplifier, it's 5 or 30 watts.

"When you are done, this unit looks like a small commercial mobile rig, not like a kit you have built."

Ten-Tec has you build the rig in stages. After you finish each stage you test and align it. They provide a blow-up of the part of the circuit you are working on with a schematic for that one section. Thus, if you do make an error, you know that everything that you have done before has checked out and you have only one small section to check for the problem. I was very careful, but when I finished the receiver and audio section, it didn't work. I found I had put a wrong value resistor in two places. I enjoyed their approach since I didn't have to wait until I finished the whole project to know that the sections were working.

The first section you build is the display driver and microprocessor circuits. When you are done, you get to see it light up. Next, you build the voltage-controlled oscillator (VCO) and phase-locked loop (PLL) circuits. Then you align the VCO using a standard voltmeter to adjust a test point for a given voltage. Then you need only check for a voltage change as you tune from one end of the band to the other. There is an optional test if you have some way of generating a 10.7 MHz signal to verify the receiver operation. The third section is the FM receiver and audio section, where you get to hook up the speaker and test the audio and squelch.

Next you build the receiver RF amplifier and mixer. Then you adjust several coils for maximum voltage and one transformer for best voice quality. You now have a working receiver, so you can start listening to the local repeaters. The memories are now functional, as are the repeater offsets.

The fifth section has you building the transmit audio, push-to-talk (PTT) and frequency modulation of the VCO. When you complete this you can transmit. Boy, is that a good feeling! Now you are close to having a working transceiver.

Next you build the CTCSS tone and packet circuits; there are no alignments or tests for this section. You proceed to the transmit RF section and then to the final assembly and testing. At this point, you can either choose to have an operational 5 watt transceiver or add the optional amplifier. Either way, Ten-Tec suggests that you test out the transceiver at the lower power before installing the amplifier. If you know you are going to install the amplifier, you'll need to substitute two heavier duty diodes while building the main unit. This will save some desoldering later.

I tuned the rig to one of the local 2 meter repeaters and gave a call. The chap who came back to me reported that the rig had a good natural-sounding voice quality and I was into the repeater full quieting, even with the rig on the 1 watt power setting. He reported no difference in either the audio or my signal quality on low power. I still get excited when a new piece of gear I've built works right.

The kit

This is a high quality kit in every way. The printed circuit board is plated through, solder-masked, and nicely silk-screened. The plated-through part really helps in making the connections sturdier so that the assembled rig lasts longer.

The kit is complete, with all components, boards, hardware, and case. A microphone is included; however, it doesn't have a DTMF pad, so you need a separate pad to use an autopatch. Or you can use one of those "Pocket Tone Dialers" sold by Radio Shack™—a DTMF keypad that you place over your mike. It is designed to produce tones for systems (phone) that have no DTMF capability. Their least expensive one (43-145) is $17 and the next one up (43-146) with 33 memories lists for $25.

Most of the coils are pre-wound. Those that aren't are very simple to wind and there are clear instructions on how to do that. The case is very nice looking. When you are done, it looks like a small commercial mobile rig, not like a kit you have built.

I found the manual outstanding. It's very thorough, but doesn't include page after page of pointless details. The kit went together very easily for me. The few minor problems I had were my own fault. If you run into a problem while building the kit and call for help, you might very well discover that you're talking to the person who designed the rig.

> ***"This kit makes it possible for even a no-code Tech to have the fun of building a transceiver and the pride of operating something they've built."***

This kit makes it possible for even a no-code Tech to have the fun of building a transceiver and the pride of operating something they've built.

The completed transceiver works great! It's easy to program and use. Even without the optional amplifier, you should have no problem getting in full quieting to most local repeaters. I have had no trouble getting into any of the five local repeaters on low power without the optional amplifier. For more distant repeaters, you might want to go for the optional amplifier. If you build the amplifier later you add a very simple board onto a big heat sink, desolder two diodes from the main board, and put in a jumper. The s amplifier board fits on a heat sink which attaches to the back of the rig.

It doesn't take much of a power supply to run the rig. 13.5 VDC at 1A on low power and 5A on high power. The completed unit weighs only 2-1/2 pounds (and that's with the amplifier added), so you can even take it along on camping trips.

$195 for a kit of this quality is a real bargain. Who says amateur radio is an expensive hobby? I recommend the Ten-Tec T-Kit #1220 highly.

For more information contact Ten-Tec at 1185 Dolly Parton Parkway, Sevierville TN 37862-3710. Or call their information line at 423-453-7172.

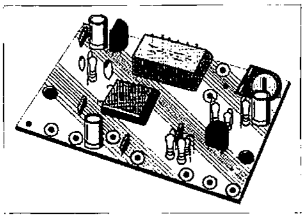
New Products

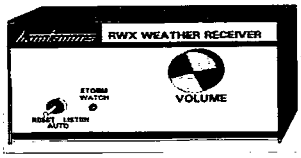


New CTCSS Encoder/Decoder Module

Hamtronics has a new version of their long-popular Subaudible Tone Encoder/Decoder module. The new TD-5 has several new features, including crystal control for precise tone accuracy and a convenient DIP switch for tone selection without test equipment.

The TD-5 will let you use your existing FM transceiver to access all your favorite closed repeaters. The thorough manual shows you all you need to know about encoding and switching and selecting tones, and helps you install the module in any transceiver. If you need a receiver decoder, the same TD-5 can be used to mute receive audio unless the proper tone is present on the signal. A convenient control line can be used to unmute the receiver manually to allow monitoring, and a high-pass filter gets rid of annoying tone buzz in the speaker audio.

And it's only $39—what a deal! That's the kit price, of course, but it's only $59 factory-wired and tested. For more details, write to Hamtronics, Inc., 65-D Moul Rd., Hilton NY 14468-9535; call (716) 392-9430 or FAX (716) 392-9420. While you're at it, ask for their complete catalog, and please tell them where you saw this announcement.



Professional-Quality Weather Alert Receiver

The new RWX Receiver from Hamtronics, Inc., the leading supplier of narrow-band FM receiver and transmitter modules for hams, is just what you need for demanding applications. Airports, police and fire departments, CAP, rescue crews, broadcast stations, amateur repeaters, local emergency managers—anyone who needs up-to-date weather information and emergency warnings—can depend on the RWX Receiver. Because of its reasonable price, it's also handy for bikers, hikers, boaters, farmers, hunters...well, who *couldn't* sometimes use an automatic "Storm Watch" alert? That's only one of the RWX Receiver's many features.

The RWX Receiver is small enough for emergency or portable use, and can be powered by a 9-12V battery when needed. It's crystal-controlled for accuracy, and all seven channels are provided, including the new split channels.

For economy, get the PCB module in kit form for only $79. With Hamtronics' thorough instruction manual, you'll find it easy to build and align. You can also buy the kit with a cabinet, AC power supply, and built-in speaker for only $99. And if you decide to take the easier route, the unit is available factory-wired and tested with an attractive metal cabinet, speaker, and power supply, for $139.

For more details, write to Hamtronics, Inc., 65-D Moul Rd., Hilton NY 14468-9535, or call (716) 392-9430. Ask for a data sheet on the new RWX Receiver. While you're at it, let them know where you read this announcement.

HamCall CD-ROM

Buckmaster's HamCall CD-ROM April 1996 edition is now available, from Buckmaster or your dealer. Get complete US and extensive international listings—over 1,290,000 callsigns, including clubs, military, and RACES listings, with more than 110,000 cross-references from old to new calls. You'll have all the data you need right there in front of you, and you can print lists and labels, edit records, even look at photos of many hams. Photos/QSLs appear automatically in Windows©, with the touch of a button in DOS. Your photo or QSL can appear in the next update, free! Find out more by contacting Buckmaster, 6196 Jefferson Highway, Mineral VA 23117; Phone (540) 894-5777 or (800) 282-5628; FAX (540) 894-9141; E-mail at info@buck.com.

Low-Cost Boom Microphone Headset Kit

The new Model TR-2000 is specifically designed for amateur radio applications, and features a noise-canceling electret microphone with a "tailored" frequency response. The flexible microphone boom is spring-loaded to provide a mechanical memory for the user's adjustment. Received signals through the moving-coil ear speakers are crystal clear. The large plush earmuffs aren't just comfortable; they add to the noise-canceling feature, allowing good performance even under high-background noise conditions.

The Model TR-2000 is compatible with the majority of contemporary radios—fixed station, mobile, hand-held, HF, VHF, and UHF, as well as many vintage rigs.

The Model TR-2000 is an easy-to-assemble kit with step-by-step instructions for $44.95, or assembled and tested (without connectors) for $64.95. Both options are available with a 30-day, money-back guarantee from Warren Gregoire & Associates, 229 El Pueblo Place, Clayton CA 94517. For additional information, call (800) 634-0094 or (510) 673-9393.

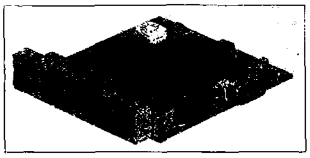
CABLE X-PERTS, INC.'s New Catalog Is Invaluable!

If you're replacing or adding cable of any kind at your station, or just getting started, you'll find this new catalog essential. It's a complete listing of cables, technical information, prices, and now detailed pictures and connector installation instructions. All this, and more, for a business-size SASE sent to: CABLE X-PERTS, INC., 416 Diens Dr., Wheeling IL 60090.

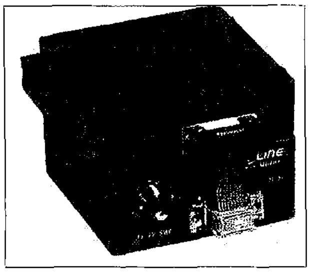
RF Applications Digital Wattmeter

A *digital* wattmeter? The P-2000A is a digitally-driven analog meter that indicates peak RF power and VSWR. This little $299 baby automatically selects the 200- or 2000-watt range for you. It has an SWR alarm which you can set to trigger when it goes over a certain SWR. Write RF Applications, 9310 Little Mountain Rd., Mentor OH 44060, or call 800-423-7252 for even more reasons to buy it.

Alchemy Today by Chris Illert. Subtitled: A beginner's guide to Hadronic circuit diagrams and secrets of cold nuclear fusion. This large 172-page archival quality (very heavy paper) book is a lavishly illustrated introduction to the latest concepts in atomic physics. Well, atoms are made up of electrons, protons, and neutrons. And they're made up of quarks. And quarks are made up of omegons. And what are omegons made of? Strings of Green Energy Balls, as originally describedby Bessant and Leadbeater in 1895. Aha, so what is "energy?" Never mind, just get the book and catch up with the weird places theoretical physics has gone in the last few years. Warning: this book is not easy going. However, if you're interested in learning about how cold fusion works, this book is a fine primer. $60.00. From Radio Bookshop. (Order form on page 88.)



Optional Module for Skyline-RTU



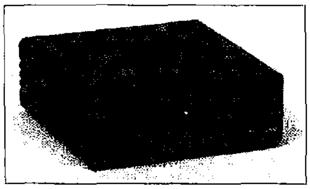
Skyline-RTU

Skyline-RTU with a No-Cost Repeater Option

Does it get any better than this? RF Neulink is now shipping its Skyline-RTUs with a no-cost repeater option; the repeater function is implemented via the serial port. Each RTU is a fully integrated subsystem that includes a UHF transceiver, RS-232 modem interface, and a digital/analog I/O board. The standard device provides for eight optoisolated digital inputs/outputs, and two analog-to-digital converter terminals. The I/O modules are stackable up to eight units, providing a combination of up to 64 digital I/O and 16 A/D terminals. Optional RTU modules are available with eight channels in and out, and four channel relay output ports.

The radio modem platform is the Neulink 9600, a high-speed, 9.6 Kbps, 2 watt transceiver modem. Up to 64 RF channels can be programmed into internal memory. Additional features are 16-bit CRC error detection, RTS/CTS, XON/XOFF, or no flow control. With its 65,000 unique ID codes, this synthesized UHF modem can be configured for point-to-point and point-to-multipoint networks.

For more information, contact RF Industries, Neulink Division, 7610 Miramar Rd., San Diego CA 92126; phone (619) 549-6340.



Versatile New Telephone Interconnect

Communications Electronics Specialties has released the first in a new series of telephone interconnect devices that will allow land mobile radio users easy access to the telephone network. The new simplex and semi-duplex 4700VP can be easily installed into nearly every repeater/transceiver on the market; it has an automatic setup feature and can be programmed locally or over the air.

The 4700VP is the lowest cost, smallest size unit on the market, but it's loaded with features like 25 speed-dial locations, 10-digit connect/disconnect code, pulse or tone dial, lightning protection, full-feature toll restriction with inclusion and exclusion numbers, built-in audio path and last number redial. For more information, telephone CES at (407) 679-9440, FAX them at (407) 679-8110, or write to: 925-122 S. Semoran Blvd., Winter Park FL 32792.

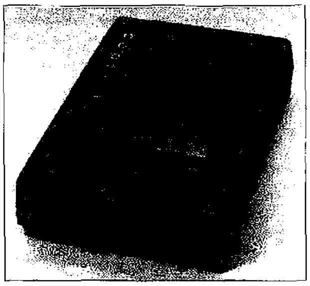
Final Quantum Revelation by Kiril Chukanov. Subtitled: General theory of world organization. This 400 page book is also lavishly illustrated. It is also tough going at times (lots of equations), but it covers an amazing range of topics. Ball lightning as a potential source of power, cold fusion power, etc. Chukanov got his information via a series of revelations from a supermind, but you'll see that he's backed up his theories with good solid lab work. He covers the fundamental laws, elementary particles, chemical elements, quantum boundaries of the world, the solar system, the galaxy. $35.00 from Radio Bookshop. (Order form on page 88.)

QSL Contest

Did you buy your QSL off a rack, or did you put some thought and creativity into it? If you think you have a winner, send it in and let us have a look at it. Who knows, it might make the cover. Well, maybe page 85 or so. Or maybe Wayne's wastebasket. If it's declared a winner, you'll get a CD of your choice of any of 26 kinds of music, as listed in Wayne's November editorial. You'll also see it in 73!

Send it to:

QSLContest,
73 Magazine,
70 N202,
Peterborough NH 03458-1107
Bribery? You Bet!



New Compact Voice Logging Recorders

Whenever it's important to verify every detail—emergency calls, contesting, meetings, or the like—Omnicron recorders provide assurance. Slow-speed recording allows up to 16 hours of talk time on a standard audio cassette, and their time track option documents time and date on a separate channel throughout all recordings. VLR recorders also permit monitoring during recording, making them ideal for those of us who are trying to do two (or more) things at once!

Additional standard features include voice-activated recording, alarms to prevent operator error, a 2X ANSI tape position counter, dual headphone jacks, and advanced automatic record level circuitry. Priced from $340, VLR recorders are available with a complete line of accessories, including the TCC-14 time/date source.

For more information, contact Bill Jones at Omnicron Electronics, 581 Liberty Highway, Putnam CT 06260; telephone (860) 928-0377; FAX (860) 928-6477.

PowerAlert™ Software Now On CD-ROM

Tripp Lite's PowerAlert Plus network power management software is now available on CD-ROM for easy installation. All versions of PowerAlert Plus include cabling and come on a single CD-ROM covering Novell, Windows 95/Windows NT, OS/2, UNIX, HP-UX, and HP Openview operating systems. The CD-ROM also includes Tripp Lite's Novell SNMP agent that allows SNMP management without external adapters.

PowerAlert Plus measures and displays power parameters such as maximum and minimum line input voltage and line frequency from any workstation or server, and logs all the information. It also provides comprehensive records of power disturbances, pools alarms, and stores alarm setpoints, enabling tracking to the problem's source. PowerAlert Plus also monitors and graphically displays battery power, percent of UPS load and internal UPS temperature, allowing precise knowledge of conditions and alerting the network manager to potential problems before they occur.

PowerAlert Plus is the only power management software available on CD-ROM covering so many systems on a single disk. It's available separately for $89 or bundled with Tripp Lite's SmartPro UPS systems. For more information, call (312) 755-5401; FAX (312) 644-6505; E-mail: info%tripplite@mcimail.com; or at web site http://tripplite.com.

CARR'S CORNER

Analog-to-Digital (A/D) Converters

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

Some things you oughta have

When we think of ham radio stuff we normally think of a shiny new SSB transceiver with digital readout, digital signal processing, a pan adapter oscilloscope to check for gaps in the band where one might set down and call "CQ," all of which costs more than I paid for my first new car (of course, it's relative—I paid about the same for that car as my father paid for his first house). There are, however, a number of things that are handy to have around the ham shack. Let's take a look at a few of them.

Dummy loads

The dummy load, or artificial aerial as it is called in the UK, is a resistor used to simulate an antenna when adjusting a transmitter or other radio apparatus. These devices consist of a noninductive 50-ohm resistor inside a shielded enclosure.

The dummy load offers a couple of benefits over regular antennas. First, it is a nearly constant impedance over the entire frequency range, and, second, it does not present any appreciable reactance. Third, and perhaps most important, the dummy load provides the ability to conduct tests off the air where you won't cause TVI, BCI, or interference to other users of the test frequency that you select. Besides, it is illegal and just plain rude to radiate when you don't have to!

One use for dummy loads is to adjust antenna tuners. You can connect the dummy load to the antenna output of the tuner, and then adjust the controls for best VSWR at a number of frequencies. By recording the knob settings, you can "rough in" the antenna tuner when changing frequency.

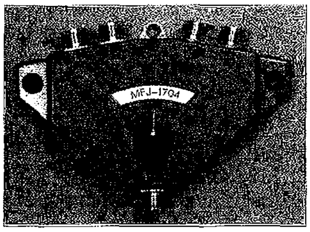


Photo A. *Coaxial switch.*

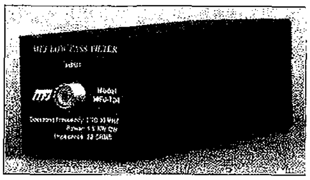

Photo B. *Low-pass filter*

Coaxial switches

A coaxial switch (**Photo A**) is used to allow a receiver or ham radio set to use any of several antennas (up to 16-port models are available, but this one is a four-port model). The common connector is for the receiver or transmitter, while the antennas and/or dummy loads are connected to the "A," "B," "D," and "E" ports, respectively; the "C" port is for the coax line to the rig. Alternatively, one can turn the switch around backwards (it's bi-directional, after all), and use the same antenna on two different receivers or transmitters.

The use of the coaxial switch in antenna measurement is in comparing the antenna being tested with either another antenna or a dummy load. The kind of off-the-air checks that amateurs can make are notoriously inaccurate, but can be made a lot more useful by making comparisons with known antennas. For example, a friend of mine, the late Johnnie H. Thorne K4NFU/5, had an antenna farm in Texas (and it did seem that he grew antennas, judging from the number he had). He kept a standard dipole, optimally installed and cut for 20 meters, and made all of his test designs for the same frequency. He would compare new designs to the dipole by switching back and forth while monitoring the signal strength on the receiver's S-meter. He could also compare two different antennas by comparing them against each other or against the dipole. Not perfect, and anyone with a professional antenna range would sneer, but it worked for ham purposes.

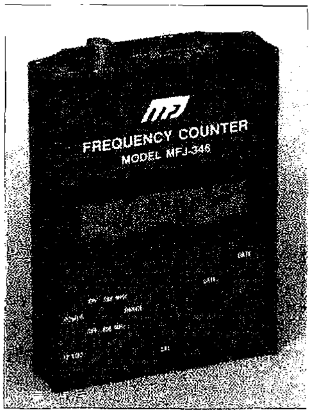

Photo C. *Digital frequency counter.*

Low-pass filter

A low-pass filter (**Photo B**) is a frequency selective device that passes frequencies below the cut-off frequency, and attenuates frequencies above that point. So why do we need a low-pass filter? Because all transmitters produce harmonics, i.e., signal at frequencies that are integer multiples of the fundamental frequencies (14 MHz is the second harmonic of 7 MHz, while 21 MHz is its third harmonic, etc.). Although there are legal specifications of how little harmonic energy you are allowed to produce, and we would like to radiate zero power at the harmonic, all real transmitters produce some harmonics. The problem gets worse when the antenna is resonant on the harmonic or the transmitter is either improperly adjusted or defective.

The main purpose of the low-pass filter is to prevent harmonic energy from HF ham transmitters from clobbering television reception. The typical ham low-pass filter has a cutoff frequency at some point above the 10 meter ham band, but below TV channel 2. If a harmonic is produced by the transmitter, then it will be attenuated by the low-pass filter before it does any damage.

Digital frequency counter

At one time, digital frequency counters (DFC) were terribly expensive. Even "cheap" models cost about the same as new cars of that era, and they were heavy, as well as power hogs. Those DFCs were really open only to professionals and that top elite of rich hams. The rest of us used a receiver and crystal calibrator to measure frequency, more or less (although I've seen some pretty good results using cheapo equipment during the old ARRL Frequency Measurement Tests).

Today, the situation is different. While the best DFCs are still costly, there are a number of ham-grade instruments on the market (**Photo C**) that are very reasonably priced, and will allow you to measure frequency accurately enough for most ham uses. These battery-powered devices make the use of the DFC a game for all.

Doing DC

One of the aggravating things about my ham shack, as well as my computer desk, is the ugly wall-warts hanging out of every available 120 VAC outlet. Every accessory that you buy these days seems to be powered by a wall-wart transformer, and there just simply isn't space for all those power modules. **Photo D** shows a DC power strip. A single DC power supply is input to one end, then up to seven devices can be plugged into the DC outlets. A DC voltmeter on the strip reads the value of the applied voltage.

Connections ...

I can be reached via snail mail at the address above, or via Internet E-mail at carrjj@aol.com.

Photos for this column were supplied by MFJ Enterprises, Inc., P.O. Box 494, Mississippi State, MS 39762.

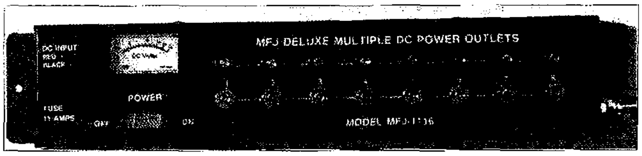

Photo D. *DC outlet strip.*

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

A key part of every satellite station is the antenna system. While small, simple antennas are great for experiments and portable use, they make most contacts via satellite difficult and less enjoyable. The end result is fewer contacts, less fun, and eventually disinterest in this exciting facet of amateur radio.

Most newcomers to OSCAR (Orbiting Satellite Carrying Amateur Radio) start on the analog LEO (Low Earth Orbit) hamsats, like RS-10 and RS-12, using simple antennas. Successful enthusiasts study the deficiencies of their systems and make corrections. With some experience, they eventually go on the digital satellites like KITSAT-OSCAR-23 and 25, and the high-orbit hamsats like AMSAT-OSCAR-10 and 13. The others go back to HF and local repeaters.

Successful LEO antennas

Most ham stations already have sufficient antennas to get started with LEO satellite work. Almost any antenna cut for 10 meters will receive RS-10. A dipole or inverted-V with a reasonable coax run and a sensitive receiver will do the job. For many this will be their final receive configuration, providing effective results for hundreds or even thousands of satisfying contacts.

Improvements require experimentation and will be location-dependent. Antennas that work include horizontal loops, verticals, turnstiles, eggbeaters and yagis. Due to the different radiation patterns of these antennas, some perform better than others during a given satellite pass. The vertical and the yagi may do well for DX contacts when the satellite is on the horizon, while the dipole or turnstile will have better reception when the satellite is overhead. One option is to have two or three different 10 meter antennas hooked to a coax switch in the shack. When reception on one antenna is bad, try a different one.

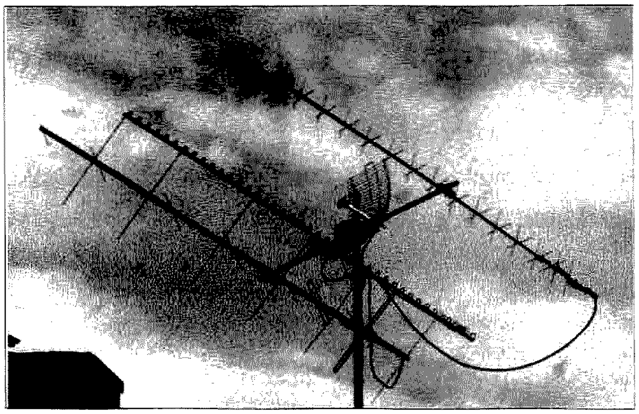

Photo B. An array of antennas for A-O-10 and 13 work at WA5ZIB includes (from left to right) a KLM 2M-14C for 2 meters, a Down East 45-element loop yagi for 23 cm, a Bob Myers dish for 23 cm and a Hy-Gain 215SAT for 70 cm, all on a nine-foot Fiberglas™ boom.

"Getting a 2 meter signal up to RS-10 is almost as easy as receiving signals from the satellite."

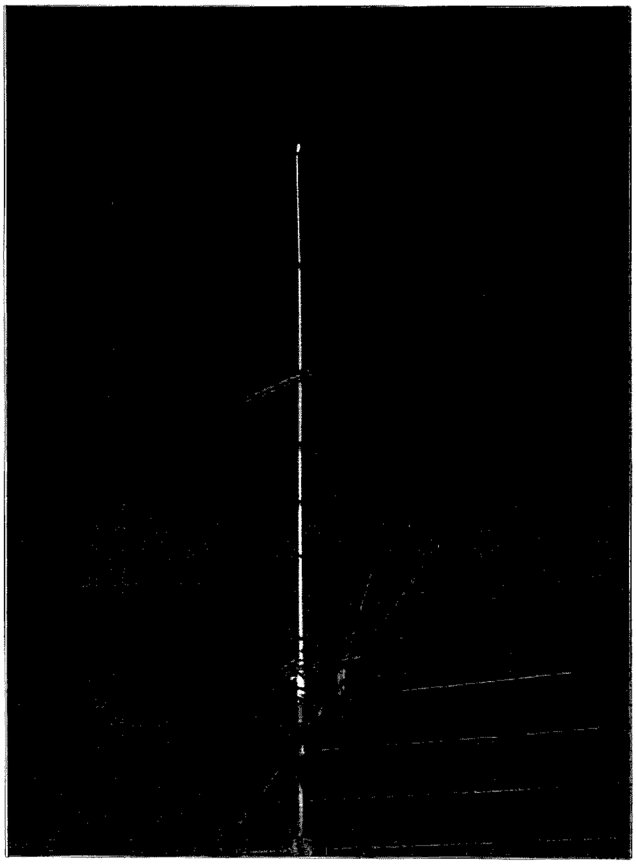

Photo A. A vertical mounted above the TV antenna does a great job for the RS-10 uplink on 2 meters.

Getting a 2 meter signal up to RS-10 is almost as easy as receiving signals from the satellite. Almost any omnidirectional vertical antenna in the clear will work with a 25-watt transmitter. While there are several commercial antennas to choose from, others, like ground planes and J-poles, are easy to build. For the 15 meter uplink of RS-12, a dipole with a 25- to 100-watt transmitter will do the job.

Antennas for the high-orbit hamsats

While most LEO satellites have altitudes of 1,000 miles or less, the high-orbit DX satellites like A-O-10 and 13 have apogees or high points out to 24,000 miles. The signals from these satellites are much weaker. Better antennas are needed to make reliable contacts.

The current high-orbit satellites use frequencies in the 2 meter, 70 cm and 13 cm bands. After the launch of Phase 3-D, later this year or early next year, we will have a satellite spanning ham bands from HF up through 24 GHz. The bands covered by A-O-10 and 13 will be very popular on P3D, and provide future P3D users with an opportunity to get ready for the new satellite by getting systems running now. Signals from P3D are expected to be at least 8 dB better than the signals from A-O-13, but not for all passes. Setting up an antenna system for reliable activity through the current satellites will insure great operation through P3D.

VHF and UHF satellite antennas don't need to be up high, they just need to "see" the sky. It's best to have an unobstructed view of the horizon in all directions. Trees and buildings attenuate both received and transmitted signals. Commonly used antennas for 2 meters and 70 cm are circularly-polarized commercially-built crossed yagis. Manufacturers include Hy-Gain, M-Squared, KLM, Tonna and others. The first four brands are the easiest to find.

One package includes a 20-element 2 meter crossed yagi, a 16-element 70 cm crossed yagi, and a mounting boom with mounting plate suitable for use with the

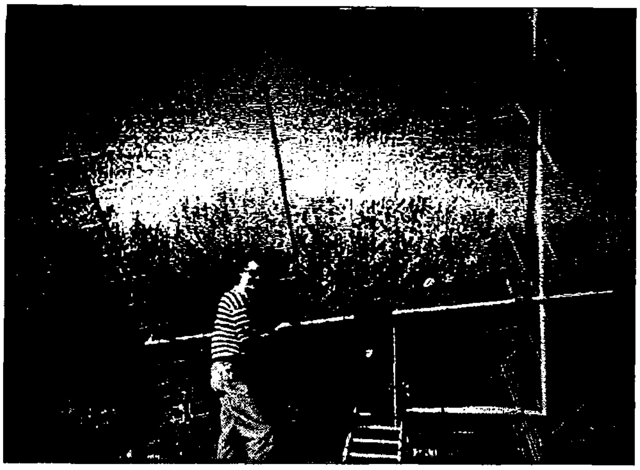

Photo C. Bruce KK5DO doing some maintenance on his rotator system. The antennas include an M-Squared 2MCP22 for 2 meters and a pair of 436CP30s for 70 cm.

Alliance U100 rotor (used for elevation control). It does not come with polarization switching, but it is the least expensive. The cable harness typically is set for RHCP (right-hand circular polarization) to conform with most satellites. The individual antennas, cross boom and mounting plate can be purchased separately, if necessary. A polarity switcher is available for the 70 cm antenna, and a 10-element 2 meter crossed yagi is an alternative for those with space constraints. The smaller antenna exhibits less gain.

The OSCAR Link antenna system from Hy-Gain offers advantages over other systems, but costs a little more. It includes a 16-element 2 meter crossed yagi, a 30-element 70 cm crossed yagi and a heavy-walled Fiberglas™ cross boom. The hardware is stainless steel with ultraviolet stabilized plastic insulators. Many other items have been carefully engineered, including polarization switching relays rated at 200 watts. For a cost-effective system with excellent performance, this antenna array is the best choice.

A newer company called M-Squared sells several types of satellite antennas. The most popular models for effective communications through A-O-10 and 13 are the 2MCP14 and 436CP30, for 2 meters and 70 cm respectively. The 2MCP14 has 14 elements and a 10-foot boom, and matches well with the 30-element 436CP30. M- Squared also has longer versions of these antennas, and omnidirectional eggbeater antennas for both bands. Quality components are used throughout. Many satellite enthusiasts have had excellent results with M-Squared products.

The finest, and also the most expensive, antennas are made by KLM. Two versions of the 2 meter crossed yagi are available. One has 14 elements and the other has 22. Just the 2M-22C (22-element antenna) includes switcher and stainless hardware. For 70 cm, there is either an 18-element or 40-element antenna.

More information

If you would prefer to build your own antennas, or to study the topic of antennas for space communications, consult *The ARRL Handbook, The ARRL Operating Manual, The Satellite Experimenter's Handbook*, many AMSAT publications, and the AMSAT HF and satellite nets.

Many discussions on the Internet through amsat-bb@amsat.org have approached the topic of effective antennas. To subscribe to amsat-bb, send a message to listserv@amsat.org. In the body of the message, simply type "subscribe amsat-bb." The system is not automatic, so it may be a few days before the mail starts coming through.

Ham Radio Fun

Number 64 on your Feedback card

Communications Simplified, Part 8

The secret world of FM.

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Last time we looked at AM radio; now it's time to get a bit more complicated and tackle FM, or frequency modulation.

Today, there are very few AM-only or FM-only radios made; most radios cover both AM and FM broadcast bands. So most of us listen to both AM and FM broadcast stations. Unfortunately, this often leads us to the wrong conclusions about their relative features.

Most people know that FM sounds better—it has better frequency response and less noise and interference, and can be heard in underpasses and tunnels, where AM fades out. They also know that you can hear AM broadcast stations farther away than FM stations, especially at night. They become convinced that these characteristics are true for all AM and FM. In reality, much of what we think about FM comes not because it is FM, but because commercial FM radio stations use different carrier frequencies from AM stations (VHF instead of LF), and they are allowed to use wider bandwidths.

AM broadcast station carrier frequencies are in the range from 0.55 to 1.6 MHz, and are limited to 20 kHz bandwidth. On the other hand, FM broadcast carriers lie between 88 and 108 MHz, and are assigned 200 MHz bandwidth. AM signals travel farther because of the lower frequencies, and FM signals can be heard better in underpasses and tunnels because of the higher frequencies. If AM was allowed wider bandwidths, it too could have a better frequency response. The major advantage that FM has over AM is that it resists noise and interference better.

"The major advantage that FM has over AM is that it resists noise and interference better."

Frequency Modulation (FM)

Just as amplitude modulation changes the amplitude of a carrier, frequency modulation changes the frequency of the carrier. There is also phase modulation which–you guessed it–changes the phase; we will discuss it later in this part.

Fig. 1 shows what we mean by FM. At the top, we see the audio waveform that we want to transmit (although we're talking about sending audio at this point, in reality you could send video, data, or any other kind of information via FM). In the middle is the carrier, as it would look before modulation. At the bottom is the resulting FM wave. As you can see, the frequency goes up (cycles are closer together) when the audio wave is high, and the frequency goes down (cycles farther apart) when the audio wave goes down (it could also be the other way–one goes up when the other goes down).

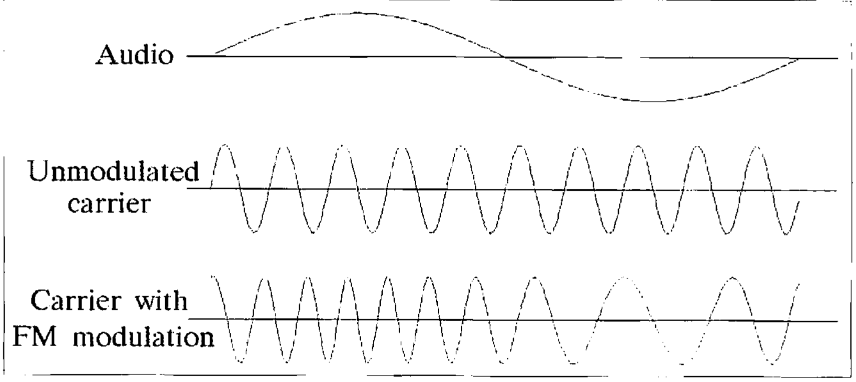

Fig. 1. Frequency modulation.

When there is no modulation (such as when an FM broadcast station transmits silence) the carrier frequency rests at what is called the *center frequency*; if you hear an announcer say "This is WXYZ on 96.3 MHz," that tells you what the center frequency is. Once the music starts, the frequency starts to vary above and below that center frequency; we say that it is *deviating* from the center frequency. *Deviation* is the word that describes how far it deviates from the center frequency.

DETOUR

Here is a short BASIC program that generates the picture in **Fig. 1**. You can experiment with it to see what happens as you change values.

```
10 'Program to generate FM
20 TWOPI=2*3.14159265
30 FAUDIO=1
40 FCARRIER=10
50 MODINDEX=5
```

```
60 SCREEN 2
70 FOR X=0 TO 639
80 T =X/640
90 AUDIO =SIN (TWOPI * FAUDIO * T)
100 CARRIER = SIN(TWOPI*FCARRIER*T)
110  FM =SIN(TWOPI*FCARRIER*T-MODINDEX*COS(TWOPI*FAUDIO*T))
120 PSET(X,50-20*AUDIO)
130 PSET(X,100-20*CARRIER)
140 PSET(X,150-20*FM)
150 NEXT X
160 IF INKEY$="" THEN GOTO 160
170 SCREEN 0
```

At 640 different values of X going across the screen, the program calculates the voltage of the *audio* signal and the *carrier* signal (whose frequencies are FAUDIO and FCARRIER, respectively), and then combines them into an FM signal. The three PSET instructions in lines 120, 130, and 140 then plot these values on the screen.

END OF DETOUR

FM differs from AM in many ways. Noise and interference usually corrupt signals by changing their voltage—by adding spikes, or in some other way changing the shape of the signal; they cannot change its frequency. Since FM signals only change their frequency, not their amplitude, it's possible to design a receiver that ignores amplitude changes (for instance, an FM radio often contains a *limiter* circuit which clips the tops off the signal to make the signal the same height no matter what level it comes in). The receiver will then ignore the noise altogether. This won't work for very weak signals, of course, since then there's nothing to clip, but for any reasonably strong signal, FM can be remarkably free of noise.

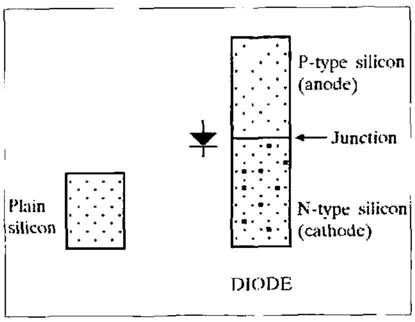

Fig. 2. Plain silicon and a silicon diode.

Producing FM

There are many ways to produce an FM signal. One way is to build an oscillator and wiggle its frequency back and forth in step with the modulation signal, using a special kind of diode called a *varicap*.

DETOUR

Most semiconductor diodes are made of silicon, which is a semiconductor—it conducts electricity, but not well, because its electrons are not very free to travel, so they cannot carry any substantial current. But it can be made into a better conductor by adding other materials to it. These make it less pure, and so are called *impurities*; the resulting impure silicon is said to be *doped*.

One type of impurity has *more* conduction electrons than silicon; since electrons have a negative charge, the resulting doped silicon is called N-type. It has an excess of electrons, and the new electrons which were added by the N-type impurity are now freer to move and therefore make the silicon into a better conductor.

Another type of impurity has *fewer* conduction electrons than silicon; this produces a lack of electrons, and leaves "holes"—places where the silicon would like to have an electron, if there were any around. This sort of doped silicon is called P-type, because these holes behave sort of like positive charges.

Think of this as a game of musical chairs. In the normal musical chairs game, there is a ring of chairs and a ring of people, but there is always one fewer chair than there are people. When the music plays, the people move from chair to chair, and when the music suddenly stops, everyone sits down. Of course, there is always one person without a chair, so he is "out," and so on. Suppose we reverse the game—instead of having one chair too few, put in one chair too many. Now there is always a chair free. As people move from chair to chair, ignore the people and instead focus your eyes on whichever chair is empty at that instant. As the people are moving in one direction, the empty chair seems to be moving in the opposite direction.

P material behaves the same way, except that the electrons are like the people, and the holes are the empty chairs. As a nearby electron jumps into a hole, it leaves another hole behind it. And so it looks as though the hole moved in a direction opposite to that of the electron.

Fig. 2 shows how this can be used to make a diode. On the left we see a piece of plain silicon. The dots show the positions of the electrons which might carry current if they were more free to move. The silicon is a crystal, and the atoms and their electrons form a neat pattern throughout the material.

On the right in **Fig. 2** we see how a semiconductor diode is made up out of two pieces of silicon. The anode is a piece of P-type silicon, while the cathode is made of N-type silicon. The place where they abut against each other is called the *junction*.

If you compare the P-type anode with the plain silicon, you will see that there are white areas where there are electrons missing; these are the holes. On the other hand, we drew some larger dots in the N-material to show the extra electrons added by the doping.

Now imagine that the diode is forward biased; that is, the anode is connected to a positive voltage, while the cathode connects to negative. Since the negative electrons are repelled by the negative voltage at the cathode, and attracted by the positive voltage at the anode, they start trying to move upward. Every now and then (quite often, actually) one of the extra electrons in the cathode will look across the junction, spot a hole on the other side, and jump into it. Of course, new electrons coming in from the negative terminal replace the lost electrons in the cathode, while the extra electrons in the anode jump from hole to hole and eventually go out the positive terminal. This gives us a current through the diode.

But now look at **Fig. 3**, which shows the diode reverse biased—that is, the anode terminal is connected to the negative terminal of a battery, while the cathode is connected to the positive terminal. Under these conditions, there is no current flow through the diode, simply because all the electrons up in the cathode are being attracted by the positive terminal of the battery, while all the holes at the bottom (which behave like positive charges) are attracted to the negative terminal of the battery.

Because all the electrons and holes are being pulled away from the junction, there is a region around the junction

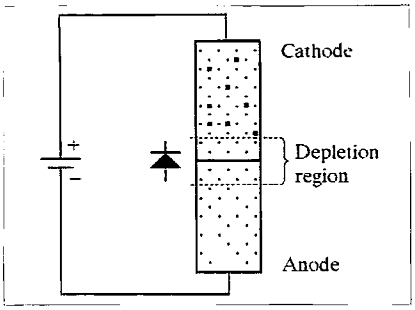

Fig. 3. Reverse-biased diode.

(sort of like a demilitarized zone) where there are no holes and no extra electrons. In electronics, this zone is called a *depletion region*, and you can see in **Fig. 3** that this region is just plain silicon-no extra electrons, and no holes.

The size of this depletion region depends on how much voltage there is. If the battery voltage is small, there isn't much pull on the holes and electrons, and the region is fairly thin. If the voltage is high, then the region becomes much larger. The depletion region acts like an insulator, and prevents current from flowing through the diode.

So the diode acts like a conductive region at the top, an insulator in the middle, and another conductive region at the bottom. That is the exact description of a capacitor—two conductors separated by an insulator. The diode therefore acts like a capacitor, but the capacity depends on the spacing between the conductors, which in turn depends on the applied voltage. Hence, this is a variable capacitor, or varicap.

Varicap diodes are specially made to exhibit large changes of capacitance with voltage, but all diodes exhibit this effect to some degree. For example, the common 1N4001 rectifier diode makes a dandy varicap for many purposes.

END OF DETOUR

Now back to FM modulation

To produce FM, we need to produce a sine wave carrier whose frequency varies with the modulation we want to put on it. One way to do this is to build an oscillator which will produce the carrier, and then vary its frequency in step with the modulation. If we use an LC circuit (a tuned circuit with an inductor L and a capacitor C) to set the frequency of the oscillator, then we can add a varicap across the LC circuit. The audio (or other modulation) is sent to the diode, changing its capacitance. This changes the resonant frequency of the tuned circuit, which, in turn, changes the oscillation frequency. Voilà—FM.

DETOUR

An oscillator is a circuit which produces an AC wave (the word *oscillate* means to swing back and forth). A typical oscillator consists of an amplifier, with part of its output sent back to the input by a *feedback* circuit.

Fig. 4 shows a circuit sometimes called a *feedback loop* or *servo loop*. An input signal (V_{in}) is applied to a combiner circuit (the circle with an X inside), and then to an amplifier which has a gain G. The output from the amplifier is V_{out}.

A portion of V_{out}, however, is sent back through a box whose gain is H, and combined with the input in the combiner; the combiner is also sometimes called a *summer* or *comparator*, depending on the application.

The normal equation for the overall gain of a servo loop circuit is

$$A = \frac{V_{out}}{V_{in}} = \frac{G}{1 - GH}$$

There are two possible things that can happen at this point, depending on whether we have *negative feedback* or *positive feedback*.

(A) Negative feedback. As we can see in **Fig. 4**, the actual input into the amplifier is a combination of the input voltage (V_{in}), and the feedback voltage. If these two signals are out of phase, then the actual input would be less than V_{in}, and, therefore, the output voltage from the amplifier would be less than if there was no feedback. In other words, the gain of the servo circuit is now smaller than the gain of the amplifier all by itself.

We can see this in the above equation. If the product of G times H is negative, then the denominator of the equation is larger than 1 (since subtracting a negative number is the same as adding a positive number). Dividing G by a number larger than 1 gives us a smaller number; in other words, the gain A of the entire circuit is smaller than the gain G of the amplifier by itself.

Since negative feedback reduces the gain of an amplifier, you may be tempted to think that it is a bad thing. Actually, though, negative feedback is used a lot because, while it reduces the gain, it also reduces the distortion of the amplifier and improves other factors. Almost every hi-fi amplifier uses it to improve operation.

(B) Positive feedback, however, is what we need to make an oscillator. With positive feedback, the signal being fed back into the summer is *in* phase with the input signal (V_{in}), and so it adds to the input. This gives the amplifier more input than it would otherwise have, and so there is a larger output voltage (V_{out}) than before.

Returning to our equation, suppose that the product GH was a positive number such as +0.5 or +0.8; it would then subtract from the 1 in the denominator, making the denominator smaller than 1. From the equation, we see that dividing the amplifier gain G by a number smaller than 1 would make the quotient larger. This increases the gain, but it also reduces the amplifier quality. If the amplifier produces some distortion, then some of that distortion is sent back to the amplifier and amplified again; the output therefore has even more distortion than before. Positive feedback is therefore not generally used in plain amplifiers, unless you need more gain than the amplifier can produce by itself.

Now, suppose that the gain G of the feedback circuit were carefully adjusted so that the product (GH) were *exactly* equal to +1. Then the denominator of the equation would be 1 - 1, or exactly zero! Since dividing the amplifier gain G by zero gives infinity as the answer, the gain of this servo loop would be infinite. In other words, there could be an output from the circuit even though there is no input. As it happens, that is exactly what we want from an oscillator!

An oscillator is therefore an amplifier with a positive feedback loop around it. The feedback loop is adjusted so that its gain H is exactly equal to 1/G at whatever frequency we want it to oscillate at

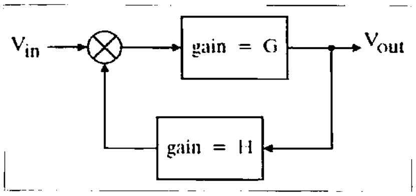

Fig. 4. A servo loop.

(so that the product of G X H is exactly equal to +1).

END OF DETOUR

Fig. 5 shows a Hartley oscillator circuit. The circuit is very simplified, and needs some more components to make it work. For example, there is no biasing for the transistor—but the important components are there. It works like this:

First, note the tuned circuit, consisting of inductor L1, and capacitor C3. This circuit sets the frequency of operation. At the same time, inductor L1 acts as an *autotransformer*. (An autotransformer acts very much like a normal transformer, but, to save money, it combines both the primary and the secondary windings into one. In this case, the entire inductor is the secondary, while the portion from the tap down to ground is the primary). Since the secondary has more windings than the primary, the output voltage from the autotransformer is larger than the input voltage and, therefore, the gain (which is actually the H in the above equations) is greater than 1.

The transistor is connected both as an emitter follower, and as a common-emitter amplifier. As usual, the emitter follower circuit has a gain slightly less than 1; this gain is the G in our previous equations. The output from the transistor goes into the tap of the inductor (the primary), while the output from the top of the inductor (the secondary) is the input into the transistor's base.

So the transistor provides the gain G (which is smaller than 1), while the tuned circuit provides the feedback H (which is larger than 1). Multiply the two out, and you get the product (G X H = 1) that is needed for oscillation. Once the transistor oscillates, the output is taken from its collector.

Now let's look at capacitor C2, and the components to its left. C2 is relatively large, so that at the frequency of oscillation it behaves almost like an AC short circuit. Hence, for AC purposes, the varicap diode

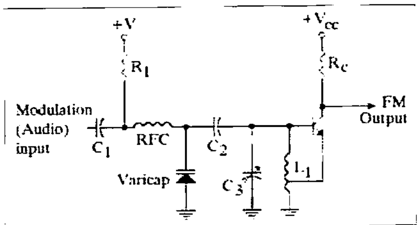

Fig. 5. A frequency-modulated Hartley oscillator.

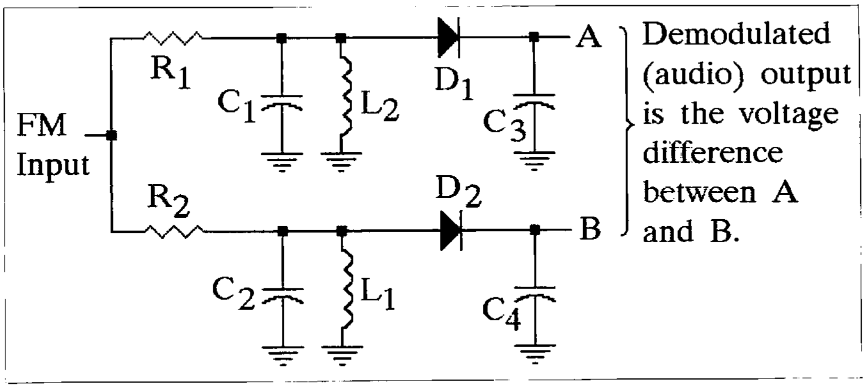

Fig. 6. A simple FM demodulator.

is connected directly across the tuned circuit. The exact oscillation frequency, therefore, depends not just on L1 and C3, but also on the capacitance of the varicap (notice the symbol for the varicap—a diode whose cathode side consists of two lines, like a capacitor).

In order to produce the depletion region in the varicap, the varicap is reverse-biased by connecting its cathode to +V through resistor R1, but note how the audio voltage comes in through capacitor C1 on the left. This audio voltage adds to, or subtracts from, the voltage +V, so the width of the depletion region varies with the audio. That changes the capacitance, which in turn changes the frequency of oscillation, giving us FM.

Finally, note the inductor labeled RFC. This is an RF Choke—a small inductor whose purpose is to keep radio-frequency signals from flowing through it. It keeps the high-frequency signal at the tuned circuit from getting back into the audio or +V bias circuit. Capacitor C2, on the other hand, does the opposite, keeping the audio and DC voltage across the varicap from getting to (and being short-circuited by) inductor L1. We can't connect the varicap diode directly across the tuned circuit since it has to be reverse biased, and the inductor would short the DC bias voltage.

There are other ways to generate FM, but the varicap circuit is the simplest and most obvious. Its disadvantage is that it produces some distortion; hence, it is most often used for voice or data communications, and seldom for high quality music.

Detecting FM

Just as there are various ways of producing FM, so there are many ways of detecting (or demodulating) it. Let's begin with the very simple circuit of **Fig. 6**.

Let's assume that the FM carrier has a center frequency of 10.7 MHz, and that it varies above and below that value. Let us tune the two resonant circuits so the top one, consisting of L1 and C1, is resonant at 10.8 MHz, while the bottom one, consisting of L2 and C2, resonates at 10.6 MHz. Further, make R1 and R2 the same, R3 and R4 the same, and C3 and C4 the same.

Start with the FM input at 10.7 MHz. The input signal is split by resistors R1 and R2 into two paths: Part of it goes to the top tuned circuit, part to the bottom. The top resonant circuit is tuned 100 kHz too high, while the bottom one is tuned 100 kHz too low, so the input signal appears across both tuned circuits, slightly attenuated (since the signal is not at resonance), but almost exactly the same amplitude.

Like the diode and filter capacitor in a power supply, diode D1 and capacitor C3 rectify the AC signal from the top tuned circuit into a positive DC signal, and filter it. Likewise, diode D2 and capacitor C4 rectify the AC signal from the bottom tuned circuit.

Since the AC signals across the two tuned circuits are about the same amplitude, the DC voltages across C3 and C4 are also equal. Points A and B therefore have the same voltage. The voltage between A and B is the actual output, which is zero.

Now suppose the frequency increases above 10.7 MHz. Since the signal is now closer to the 10.8 MHz resonant frequency of the top tuned circuit, the AC signal across that circuit increases; likewise, the AC signal across the bottom tuned circuit decreases because the input frequency is now farther away from the 10.6 MHz

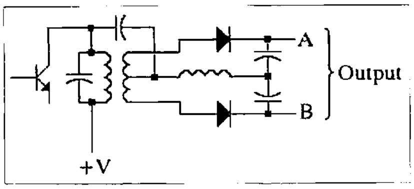

Fig. 7. Foster-Seeley discriminator.

resonant frequency of that circuit. Point A is now more positive than point B, and so the net output voltage is positive. In fact, the closer the input frequency gets to 10.8 MHz, the bigger the positive output.

In exactly the same way, if the input frequency drops toward 10.6 MHz, point B becomes more positive than A, and so the difference between A and B becomes negative. The more it drops, the more negative the output gets.

In other words, the output voltage is proportional to the frequency of the input signal—when the frequency goes up, the output voltage goes positive; when the frequency goes down, the output voltage becomes negative. This converts the frequency changes of the FM signal back into the original modulation.

While the circuit of **Fig. 6** would work, the fact that it has two tuned circuits makes it too difficult to adjust. It also has a bit too much distortion. Most receivers therefore use a slightly different circuit.

Fig. 7 shows one common circuit, called the *Foster-Seeley Discriminator* (don't confuse this with two companies, one called "Stearns-Foster," and the other called "Sealy"—they make mattresses, which have nothing to do with FM). By relying on the phase differences between several signals, the circuit produces voltages at the two diodes which depend on the frequency. By the time the signals are rectified and filtered, we again have a demodulated output which depends on frequency.

The circuits of **Fig. 6** and **Fig. 7** both have one disadvantage; their output

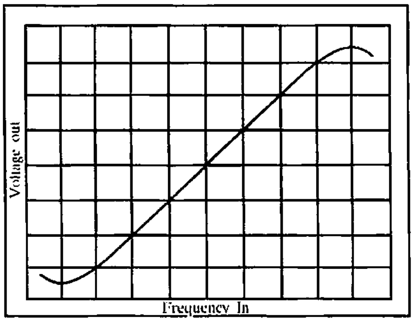

Fig. 8. The FM discriminator "S" curve.

voltage also depends on amplitude—the stronger the FM input signal, the greater the output voltage. This means that noise (which changes the input voltage) would get through the detector circuit. As we pointed out earlier in this chapter, one way to avoid this problem is to put a limiter in front of the detector; the limiter keeps the input signal at a constant height, and so avoids the problem. This means we need to add one more circuit to the radio, so many designers try to cut costs by using a slightly different circuit, called a *ratio detector*. Instead of taking the difference between the two diode outputs in a pair of resistors, the ratio detector looks at the *ratio* of the two diode voltages. Regardless of how strong or weak the signal is, at any given frequency the ratio of the two signals should be the same, and so this circuit ignores any amplitude changes in the signal. In many cases (especially in commercial FM broadcast receivers) that eliminates the need for a limiter, and cuts cost.

Fig. 8 shows the output-vs.-input curve of a typical discriminator or ratio detector; you can see why it is often called the "S" Curve. It shows how the output voltage (the vertical axis) depends on the input frequency (the horizontal axis). If the circuit is well designed, then the center of the curve should be as straight as possible, to make the output voltage exactly proportional to the frequency change, and produce the lowest distortion. The ends of the "S" curve are curved, but the FM signal usually doesn't change frequency that far up or down, so it doesn't matter.

FM sidebands

Like AM, transmitting an FM signal results in sidebands, and those sidebands increase the bandwidth of the FM signal.

Let's start by looking at **Fig. 9**. At the top, we have 10 cycles of an unmodulated carrier with a constant frequency. Note the vertical lines, which cross the carrier signal exactly at the top of each cycle. If you carefully measure, you will see that the distances between all the lines are exactly the same, which proves that each cycle is exactly the same length.

Below the carrier we see two sidebands: the upper sideband, with a slightly higher frequency (it shows 11 cycles instead of 10); and the lower sideband, with a slightly lower frequency (it shows only 9 cycles.)

In the bottom waveform, we used a computer to sum the carrier and sidebands to produce a resulting waveform. Like the unmodulated carrier at the top, it shows 10 cycles, but these cycles are not all the same width—you can see that the vertical lines cross the bottom wave at different places in each cycle. From this, we conclude that the FM signal at the bottom is changing frequency (because some cycles are longer and some are shorter), but that the average frequency is the same as the unmodulated carrier. In other words, modulating the carrier to produce FM varies the frequency back and forth, above and below the "resting" or unmodulated value.

We therefore see that, like an AM signal, an FM signal consists of a carrier plus sidebands. But there is one catch—if you examine **Fig. 9** carefully, you can see that the cycles of the FM signal at the bottom are not all the same height. In other words, the frequency is varying, but so is the amplitude. This can't be! There is something wrong here! FM is supposed to stay the same amplitude all the time, not change! What's wrong?

The problem is that **Fig. 9** doesn't tell us the whole story. **Fig. 9** would be good enough to explain FM *if the two sidebands were much smaller*. When the amount of FM modulation is very small (for example, when the music on an FM station is very soft), one tiny set of sidebands, much smaller than those shown in **Fig. 9**, is enough to swing the resulting FM carrier back and forth in frequency a small amount without changing the amplitude.

On the other hand, when an FM station transmits loud music (which produces much more modulation), the simple picture in **Fig. 9** needs something else (let's call it a "finagle factor"), something which will keep the amplitude constant.

This "finagle factor" is another set of sidebands. A real FM signal usually contains more than one pair of sidebands: there could be dozens or even hundreds of sidebands on each side of the carrier when there is a *lot* of modulation.

Fig. 10 shows how adding just one more set of sidebands can fix the problem of **Fig. 9**. Here we see the following: the original unmodulated carrier with 10

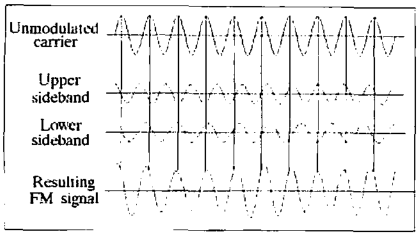

Fig. 9. FM from one set of sidebands.

cycles, one pair of 1st sidebands, an upper one with 11 cycles, and a lower one with 9 cycles, a pair of 2nd sidebands, an upper one with 12 cycles, and a lower one with 8 cycles, and the resulting FM signal with 10 cycles of varying frequency, but constant amplitude. So we see how adding just one additional set of sidebands (with frequencies different from the first set) can fix the amplitude variations.

As we mentioned earlier, with more modulation, even more sidebands might be required to keep the amplitude constant. So we need to learn how to measure the amount of modulation. This can be done in two ways—using the deviation, or using a modulation index. Two methods that will, unfortunately, have to wait until next time.

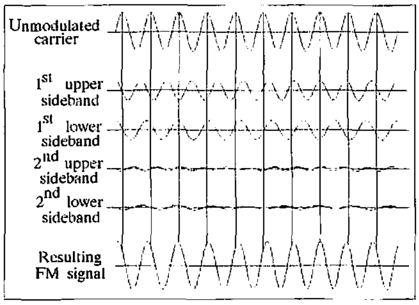

Fig. 10. Multiple FM sidebands.

NEVER SAY DIE

Continued from page 45

else. We had a ball converting the Command Sets, SCR-522s, and other stuff. And we learned from doing it.

For my part, I got started building stuff in 1937. It started with a box of old radio parts someone brought to the church and gave to my pal Alfie. He had zero interest in that old junk, so he gave it to me and I used the parts to build a cigar box radio. Which worked! I was hooked. Friends of my family dumped dozens of old radios from their attics on me. I took 'em all apart, building up my junk box. I hate to think what those old radios would be worth today if I'd boxed 'em up and stored 'em. Lordy.

Like everyone else, I memorized the *ARRL Q&A Manual* and passed my ham ticket. Sure, I could build things from magazine articles, but I hadn't a clue as to how elctricity worked. In that way I was like almost every other ham I'd met. When WWII came along we all got thrown off the air in December 1941. In 1942 I joined the Navy and they put me through a three-month course in the fundamentals of electricity at Bliss Electrical School. It was a fabulous course.

After that I went on to the Navy Radio Materiel School on Treasure Island (San Francisco) for six more months. By the time I graduated I could repair anything electronic: test equipment, receivers, transmitters, antennas, sonar, radar, and so on. Bliss gave me my understanding of the fundamentals which has helped me cope with the development of solid state, computers, and digital electronics.

After I graduated from Treasure Island I volunteered for submarine duty and was sent to Pearl Harbor as an Electronic Technician 2/c on the submarine tender Sperry. In 1943 I was transferred to the *Drum*, where I was in charge of everything electronic. And had plenty of exciting adventures...which are described in my *WWII Submarine* book.

That's the kind of thing amateur radio got me into.

Maybe now you can understand why I've been pushing ham clubs to provide technical sessions before every club meeting. These will help newcomers and old timers (too) build an understanding of the fundamentals instead of just memorizing the *ARRL Q&A Manual*, like we all did 60 years ago and newcomers still are doing today.

Not only is learning new things fun, but it also helps your mind develop. Like the rest of your body, your mind is a use-it-or-lose-it module.

If the newcomers to our ham bands aren't operating the way we want them to, that's due to what they're learning from us old timers, not what they may have brought from CB. If there'd been a CB band in the 1930s I'd have been on it and had a ball. With few exceptions, the absolute worst operators I'm hearing on our bands these days are old timers, not the no-code newcomers. That mess on 14.313 was all made by old timers. And look what K1MAN, who at 54 should know better, has been doing to our bands!

In the past our worst ever operators were all old timers. W2OY and W2BIB were infamous. OY used to sit on the low end of 75m on AM and put down sideband, newcomers, youngsters, and so on. BIB made his mark by doing his best to jam emergency medical traffic with Africa. Have any of you old timers any other nominations for the Ham Hall of Shame? Hmm, I almost forgot W2HH, who spent much of his later years jamming 75m DX contacts with CW. Say, wasn't he a former ARRL director, and the father of some forgotten ARRL president?

But for every Hall of Shamer we have ten hams who deserve medals for their contributions.

Getting back to the stuff in Florida Skip, there's a really stupid comment about the ham manufacturing and distributing lobbies influencing legislation. In some other field, maybe. But this guy, being relatively new, maybe hasn't noticed that the Japanese almost completely dominate the ham market here. Yes, they should fund a lobby, but unless it's been kept a secret (which is unlikely), they haven't. The American ham industry hasn't been able to get together to do anything. Most of 'em don't even bother to come to ham the industry meetings at Dayton. And when I offered to try and organize a manufacturer's group to work with the FCC as advisors, I got almost no response.

Twenty years ago we had an active FCC National Industry Advisory Committee (NIAC) which met in Washington with the FCC staffers to discuss ham regulatory matters. The Committee had originally been formed as a prestige deal which was completely controlled by the ARRL. Some ham FCC staffers got really fed up with NIAC doing nothing and organized a revolt which got rid of the pompous do-nothings and brought in some movers and shakers (including me). For several years all of us flew to Washington at our own expense to provide the guidance the FCC wanted and needed. I'll tell you more about that era some time.

It's a pity when ham publications help spread misinformation like that. Yes, it's a lot more trouble for writers to do their homework before writing, but then they'll be able to share their knowledge with us instead of displaying their ignorance and prejudices.

The New York World's Fair Fiasco

The Silent Key announcements for Bill Leonard W2SKE and Stu Meyer W2GHK, both around my age, got me to remembering some ham history that few hams today probably know about and most old-timers have forgotten. Bill used to be the president of CBS News and Stu was the president of Hammarlund. Both were good friends.

Bill and I spent a couple of months flying around the world together in 1959 on an Air Force C-54. We had a sideband ham station with us on the plane with which we made thousands of contacts as we flew from New Jersey to Newfoundland—Bermuda—The Azores—Scotland—Paris—Haderslev, Denmark—Berlin—Rome—Athens—Alexandria, Egypt—Aden—Karachi—Colombo—Bangkok—Saigon—Philippines—Naha, Okinawa—Taipei—Seoul—Tokyo—Guam—Wake Island—Honolulu—Travis AFB—Omaha—Dayton—Washington DC—and back to New Jersey. We got to know each other pretty well.

My story has to do with the New York World's Fair of 1964-65 and the ham radio exhibits therein. I'll tell the story as I recall it rather than digging out my old issues to get the details exact.

It all started when Bill, who was quite a celebrity as the head of CBS News, found out that Coca Cola was looking for a theme for their World's Fair pavilion. Bill called the president of Coca Cola and suggested that the exhibit be built around amateur

Number 70 on your Feedback card

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

From the spread of questions received from readers of this column, it would appear that you all divide into two basic groups. There is, of course, the experienced RTTY-phile contingent, and there is a group to whom much of this is a mystery. That latter group is the target of this and the next few months' columns.

The question to be addressed this month is, "Just how do you get digital information, letters, and numbers on a radio signal?" Remember that the technology we have today, computers and the like, did not exist when radioteletype started, so our system will have to allow for techniques of 50 or more years ago.

To begin with, understand that a "digital" signal is just one which is being turned on and off, which we can view as being alternated between a mark and a space state. So, let's begin without radio, by stringing a wire from here to there, and putting a light at one end and a switch at the other. **Fig. 1** will help with an understanding of this complex concept. If I want your attention, and I am here and you are there, I can just light the light. At the simplest level, we could even agree that one blink of the light means one thing, and two or three blinks means something else. The trouble with this scheme is that the number of blinks gets cumbersome fast.

So, along comes someone (I will leave alone the argument of whether or not it was Samuel F. B. Morse for now) who devises a code scheme that encodes all letters as groups of short or long pulses. Now we can use the wire and light to spell out words, numbers, and whole thoughts. Unfortunately, the code groups used for the letters and numbers are of varying lengths, making any attempt at automatically decoding them with some kind of mechanical device fraught with difficulty.

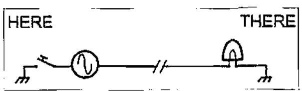

Fig. 1. A switch at one end of a wire that turns a light bulb at the other end on and off illustrates a crude form of code communication.

OK, so if we confine ourselves to just the 26 letters of the alphabet, and want to come up with a scheme that could automate transmission, we might brainstorm the scheme shown in **Fig. 2**. Here, 26 wires, one for each letter of the alphabet, are strung between two points. Extra wires could be used for numbers and punctuation, and one could even postulate stringing another wire for a SHIFT key, such as on a typewriter, to produce capital letters. Using modified electric typewriters at either end, we could have a workable scheme here. Of course, the expense of stringing who knows how many wires from here to there will be somewhat prohibitive, and looking into the mode's future, are we talking about 26 radio frequencies? The mere thought makes me shudder.

So, we have to get clever. First of all, let's look at just how you can encode information. One pulse, such as we have been using, can encode two states, ON and OFF. What if we used two pulses in sequences, each one of which can be on or off? With ON represented by "1" and OFF by "0," possible combinations would be 00, 01, 10, and 11—four distinct codes. In fact, the number of codes is two raised to the number of pulses used. So, using five pulses, 32 code groups are possible, enough to encode all 26 letters, as well as some punctuation and machine functions. A SHIFT function will give another set, for numbers and even more punctuation. **Fig. 3** shows, in chart form, the whole scheme, commonly called the Baudot or, more properly, the Murray code.

Well, we have a way of encoding the information, but how can we send it over a single wire or frequency? Well, we could back down to the multiple wire scheme, using only five wires—one for each bit of the Murray code. In fact, these days, we would call that "parallel" communication, and that really is how most computers talk to their printers. But that is not the topic of this column, and not the way radioteletype is transmitted. No, we are going to have to confine ourselves to one wire, or one frequency.

Although I will leave out some of the specifics, as they vary with machines, imagine a rotating wheel that encodes the five bits to be sent in sequence, producing a sequence of on and off pulses to describe each group. At the receiving end, we will place an identical rotating wheel, rotating at the same speed, which directs each incoming pulse to a magnet, which holds down a selector, which decodes the letter. Neat, huh? Of course, the two wheels need to be turning at precisely the same rate, and remain in perfect sync. Not an easy task, folks! Actually, this scheme is in use, and called "synchronous" transmission; it's just not the way we are used to doing it.

No, we took a simpler approach. Still two wheels, still rotating at the same speed, although speed is a tad less critical, but now add two pulses. A START pulse, always SPACE, is sent from the sending machine, and tells the receiving wheel to start rotating. Then come the five data pulses, with the receiver sampling only the middle of the pulse. By sampling the middle of the pulse, a speed drift of a few percent will not affect transmission. Finally, a STOP pulse, always MARK, concludes each character, and sets the system up for the next character. This "asynchronous" transmission, although it looks continuous, is, therefore, really a series of individual character bursts. **Fig. 4** is an attempt to diagram such a setup.

Now all you have to do is connect the two machines by wire or radio, and you have a workable scheme. As to the specifics of that radio connection, that is a topic for another column. Hopefully, this explanation helps demystify what some of you consider an enigma: Just how do letters and numbers get encoded onto one signal?

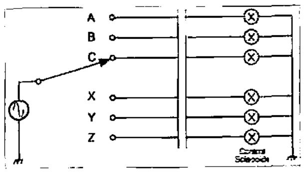

Fig. 2. A way for two machines to exchange information is to string 26 wires between them, one wire for each letter of the alphabet.

By the way, lest you think this scheme ends with radioteletype, if you expand the number of pulses to seven, you will have two to the seventh power, or 128 possible characters. Filling in all the upper and lowercase letters, numbers, punctuation, and some odd characters yields the American Standard Characters for Information Interchange, ASCII, the character set behind most computer communications. This asynchronous data transmission mode all started with a teleprinter. Imagine that!

Fast-forwarding to the present, but staying with the question of interfacing, I have a letter here from Elmer Sterkel KØUYE, of Loveland, CO, who is interested in the Snappy Video Capture mentioned a few months back. He has HP Deskjet 660C, and wonders how you hook the whole thing up.

Well, Elmer, if you only have one parallel port (see, I told you this would come in handy), you have to use a switch to select which device the port sees, the Snappy or the printer. The Snappy does not feed the printer port through, making such a switch mandatory. The alternative would be to use a second printer port, if one is available, or to install a card to create one. I purchased a switch from a local computer superstore for under $30. **Fig. 5** shows how to hook the whole thing up; it's really not very complicated. If you have a second printer port, just put the Snappy on LPT2, it will configure for that port and

function just fine. The Snappy itself is widely available, and the price seems about the same at every source I have looked at.

Good luck, enjoy, and be sure to send me a sample of your efforts for inclusion in this column and on the web site.

The RTTY Loop Home Page, by the way, is continuing to attract a good deal of interest. Check it out at http://www2.ari.net/ajr/rtty for columns, downloads, links, and information on the growing RTTY Loop Software collection. I look forward to your questions and comments, by E-mail at ajr@ari.net, on America Online at MarcWA3AJR, or CompuServe at 75036,2501; or via snailmail to the address above. Be sure to include an SASE if you desire a response to snailmail correspondence. Next month, more on the series of basic radioteletype principles.

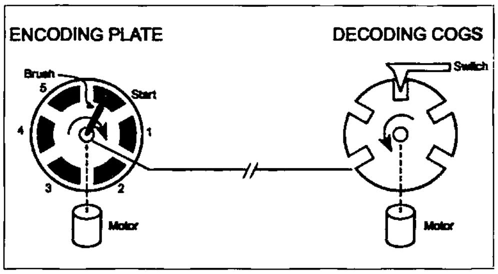

Fig. 4. The rotating wheels in each machine that spin at exactly the same speed are the backbone of "synchronous" transmission.

QRP

Number 72 on your Feedback card

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Summer will be quickly coming to a close, so let's preview a simple project to start off the winter building season. But first off, a condensed look at the QRP activity at the Dayton Hamvention 96.

QRP at Dayton Hamvention 96

The Four Days In May, for a first-time event, was a great success! All those who attended found the activity well worth the time and money. Without question, there will be another Four Days in May for 1997, but right now, I don't have the names or numbers to give you. When I know the people to contact, you'll be sure to find the information here.

The Friday night dinner was also a success! With over 100 people in attendance, it was the largest group we have had so far at the Hamvention. At the dinner, my two paid hecklers, Randy KD8JN and Scott N8JSK, conspired against me with bogus badges made up for the entire group. Somehow I became a spokesperson for a well known high power RF amplifier company. Not only did most of the QRPers at the dinner wear badges, the hotel staff did as well! Wait until next year!

Thursday and Friday nights were show and tell. Many of the vendors had equipment set up and running. S&S Engineering were showing off their new DDS VFO. Index Labs had the new QRP Plus on hand. Also on hand were the Atomic keyer, the Small Wonder Labs 20 meter SSB rig, the Wilderness Radio version of the Norcal 40, and the Sierra. I introduced my Micro "M" solar controller on Thursday evening. I know I missed some of the vendors: I always tell myself to make a list, but like the previous years, I forgot.

Clubs

We had, on Saturday night, just about every QRP club alive. The QRP ARCI, The M-QRP club, Norcal, New England, St. Louis QRP club, G-QRP, Colorado QRP Club, Northwest QRP club, and a few from out of the country. Making its debut was the QRP-L group, found on the Internet.

New stuff

I was surprised by the number of hams who were buying old QRP rigs and accessories. Heath HW-7s were going for $150. HW-8s were on the tables for over $200. Century 21s were $300, for the analog versions. In fact, someone (was that you, Doug?) purchased a used Ten-Tec microphone for the Argonaut 509 for $75! It's no wonder that the three I had on my table in the flea market went so fast. Had I known, I could have made a bundle. I had two Electro-Voice microphones, made for Ten-Tec, in the original boxes, and sold them Friday morning, as soon as the flea market opened. I wondered why the guy who purchased them didn't dicker. Oh yes, I sold the two for $20 each. The third one had no end plug—it went for $15. Oh well, live and learn!

QRP ARCI

Several items were taken up at the annual board of directors meeting. First, there will be a dues increase. The exact dollar amount has not been set at the time this is being typed. It's been a very long time since the QRP ARCI has had to increase dues, but it's become necessary because of the increases in postage and printing costs of *The QRP Quarterly*. Also, for DX members, the price of first class air mail is slowly bankrupting the club. Right now, a DX membership is $12. It costs anywhere from $3.70 to $6 for air mail, depending on the destination. It doesn't take a college education to tell you it costs more to mail out *The Quarterly* than we collect in dues. As a temporary fix, all DX members will have their copies mailed by surface mail instead of by air. This will be *only* for the short term. Look for QRP only ads to appear in *The Quarterly* as a means to offset the constantly rising postage costs.

Membership and subscription problems

If you have a problem with your membership in the QRP ARCI, contact me, not the prez, the vice prez, or the QRP-L group on the Internet. I'm the only person who can fix the problem. I, and I alone, have the database files. Write to me at the address at the top of the column. You can send E-mail at one of two addresses; 73357.222@compuserve.com or prosolar@imperium.net. I prefer that you use the E-mail going to the CompuServe address. Imperium net has been less than 50% available to me most of the summer.

Solar power revisited

Seeing three flea market spaces filled with solar modules and controllers, I noted a great interest in large high-power modules this year. In the years past, most of the QRP operators went for the 5 and 10 watt Solarex Lites. These make taking solar power and your favorite QRP rig into the field lots of fun. This year, most of the guys wanted larger, more powerful modules for use at home.

I also wanted a higher power module to increase my energy production, so I have installed two Astro power 120 watt modules on a pole mount. These modules will be used to test new control circuits. When not used for testing, their output will be redirected to the main storage battery. I plan on adding four more 120 watt Astro modules during the summer of 97. Also, two more 64 watt Solarex MSX-64 modules will be added to the main array before you read this. This will boost the peak current going into the storage batteries to over 73 amps at 17 volts. Although it isn't yet carved in stone, by the time you read this, my entire solar energy control system will be scrapped and a newer version in place. This time around we will go to a 24 volt system and use a single 3.5 kW modified sine wave inverter to supply power to the shack and the rest of the home. I will keep some of the low voltage lighting, now running on 12 volts, by using a DC to DC switching converter.

Low voltage fluorescent lighting can cause all kinds of RFI. The switching ballast used in the low voltage fluorescent lights generates a signal from DC to light! By using a separate inverter, I should be able to eliminate most of the RFI now caused by my lighting system.

A portable solar panel tester

This project came about out of a need to test surplus solar panels, without dragging along an expensive digital voltmeter. The tester will check for open circuit voltage and short circuit current of any solar module up to 180 watts. The maximum current the meter can handle is 10 amps.

The meter is very, very simple. In fact, instead of using a PC board, all components mount on a piece of perlboard. In fact, there are only a handful of parts needed.

The solar tester is built around a Jewel LCD meter display. The basic movement has a range of 0 to 200 mV. You can use just about any digital panel meter with an input of 200 mV. I've seen some really good prices for DPMs at hamfests. Some can be had for under $10.

To measure voltage, we need to scale the incoming voltage down to the level required by the meter. Since the open circuit voltage of a nominal 12 volt solar panel is around 21 volts, I scaled the meter to display a 200 volt range. So, when connected to an open circuit solar panel, you'll see 21.0 volts displayed. The 200 volt scale was needed because the meter would display an over range error if scaled to a 20 volt range.

To set the meter's scale, two .1%-tolerance resistors were used. These guys are available from Mouser Electronics™ for about two bucks each.

This gives us the voltage measurement. To measure current, I used 10 .1 Ω 5 watt power resistors in parallel. The total resistance for the 10 resistors is .01 Ω. With the meter's nominal 200 mV input across the shunt resistors, 10 amps of current will drop 100 mV, so the meter will display 10.0 amps. The combined wattage of the shunt resistors is 50 watts—the shunt should be able to take a 10 amp reading for 15 seconds or so before heating up.

The hardest part of the project is coming up with a simple

Your E-Mail Classroom Connection

NTS and digital communications.

Pete Kemp KZ1Z
Bethel Educational ARS
Bethel Middle School
600 Whittlesey Dr.
Bethel CT 06801-1594

Students love to communicate. They don't want to feel left out of anything! Many female middle school students are even known to write lengthy messages to fellow students, chock-full of all the latest information, when the slightest need is perceived. To harness this energy, and to take advantage of middle-schoolers' innate desire to know what other students are doing everywhere, radio E-mail fills the bill. While landline Bulletin Board Systems (BBSs) can pass E-mail, you need a modem and a computer to receive the mail. Using packet, you have the option of utilizing the ARRL's National System (NTS) for delivery via a friendly telephone call or communicating directly with other schools who use packet radio.

To use packet radio in the classroom, proper preparation must be made for a successful experience. A number of issues must be addressed:

What equipment is needed?

A basic packet radio system consists of a VHF transceiver, antenna, Terminal Node Controller (TNC), and computer/software or data terminal. You don't need to have a big full-blown VHF monster station to participate actively. A successful project may be accomplished from a permanent station, or a portable one, using a laptop computer. TNC. and an HT with a rubber duck antenna.

         All the Best of the Holiday Season!
                   from
            KZ1Z and the BEARS
The Bethel Educational Amateur Radio Society
```

Fig. 1. Sample message.

What is the purpose of your communication?

Before sending out any message you must have a purpose. No one appreciates radio junk mail; it ties up nets and clogs up busy packet frequencies and computer space on packet bulletin boards. Some message subjects to consider when starting out include interdisciplinary work combining technology and language arts, computer science, art, science, math or other academic disciplines of the curriculum. The beauty of this medium is that you are limited only by your own imagination and common sense.

```
| We hope that you had a great summer. The school year |
| ahead is ripe with opportunities for personal and |
| academic growth. The BEARS wish you a fantastic |
| school year filled with ham radio fun. |

Fig. 2. Sample message.

Surveys requesting information on a variety of subjects, such as political straw polls, musical groups, or other student-oriented issues, will usually strike a responsive chord among fellow students. Data retrieval for scientific interpretation or mathematical statistical work is an excellent first project for packet E-mail. For example, you may ask participants to send in the high and low temperatures for their area on a specific day or week, identifying their geographic location by using longitude and latitude. The data may be used for lessons in social studies classes, for meteorology lessons in science class, or in mathematics for drawing charts and graphs. You could even share the data for input in computer science classes for spreadsheet work, transforming the data into a variety of graphic representations.

Celebration messages are a lot of fun. Students can send messages to other students and schools wishing them all the best during a holiday season, congratulating them after the school has received an honor or award, or praising a successful sports endeavor.

ASCII graphics can be especially effective for spicing up messages via non-NTS (the ARRL National Traffic System) circuits. Keyboard art has been a part of amateur radio for years on RTTY and it has a place on packet. too (be careful not to send long pictures, as they won't make you many friends in the packet world). Recent software and TNC developments also allow for ANSI picture transfers, but special care must be taken to be sure that the format is appropriate, as you would not want to send control characters, which may be misinterpreted by non-compliant systems. ANSI graphics are not compatible with DX packet clusters.

Just being a nice person has its own rewards and is an ideal way of facilitating personal communications. Consider contacting former students who have moved away from the community, just to ask how they are doing. A friendly message from back home is always appreciated. Packet may also be used to

```

Fig. 3. Sample message.

keep alumni students informed of local events and reunions. "Happy Birthday!" messages are always fun. You may wish to seek out new students at your school and ask them if they would like to send a message to a friends back at their old schools or communities. This is an excellent way to bridge that awkward gap that exists whenever a student moves to a new town. It also gives students an opportunity to learn more about their peers and about other areas of the country. Military personnel also appreciate being remembered. Radio links in conjunction with MARS should also be explored.

What system would be best for getting the message out?

NTS, the ARRL-sponsored National Traffic System, is an excellent way to get the messages out. Disseminating messages through NTS keeps the system alive and builds strong ties in the local and section levels.

While we often think of packet as the primary method of getting the messages out digitally today, you should not overlook the potential use of other modes, such as APLINK, AMTOR, PACTOR, HF packet, and RTTY. Many areas of the country also have long-established VHF packet to HF digital links.

Message preparation

Messages should always be prepared in accordance with proper NTS format (see Appendix A) if you are not sending a message to a specific amateur radio station's home BBS. It is recommended that you also have a copy of the ARRL numbered radiograms.

The effective use of a text editor to prepare your messages off-line is strongly advised. This will allow you to verify content information, to check spelling, and to generate a bulk loading text file to upload messages efficiently. See Appendix B for details. Remember to always save your messages in a pure ASCII format. Imbedded control characters associated with specific word processing programs will cause problems during transmission and later printing.

If you will be uploading messages to a local BBS on a steady basis, it is a good idea to contact your local sysop ahead of time to set up forwarding paths and to see what other suggestions he or she can offer.

Have fun!

Infusing radio E-mail into the classroom offers many opportunities and readily yields positive results. The educational process is enhanced by such hands-on practical activities. Many pen pals and long-lasting friendships (and funny stories, too) have been garnered through this medium. One divorced mother, living in another state, received a message from her son, delivered by a friendly radio amateur operator. The son reported to the class that his mom called him on the telephone late that night all excited to say that she had received his note. She then asked him to send another message, so she could chat again with the gentleman who delivered that previous message! One never knows where the power of E-mail will take you.

Working with digital communications over radio is like second nature for today's students who have grown up with computers, as they begin to understand that the Super Highway of tomorrow will extend to the sky, and will not be limited to traditional landlines.

Fig. 4. Sample message.

Appendix A: ARRL Radiograms

The handling of radiogram traffic was the basis for the formation of ARRL, and a sizable segment of amateurs still makes this its principal amateur radio operating activity. Amateur radiogram service does not compete with other services, since there are no charges and there can be no guarantee. Provided FCC and international regulations are complied with, messages may be accepted from anyone for sending by amateur radio.

What constitutes "legal" messages, or any other kind of third-party communication, has been a matter of considerable discussion and various interpretations throughout the years. The pertinent regulations sections are: 97.3b, which defines an amateur operator as being a person "without pecuniary interest;" 97.112, which forbids any remuneration or other kind of compensation for use of an amateur station; and 97.114, which details certain prohibitions on third-party traffic.

Generally speaking, personal, non-business messages may be exchanged between different countries only after a special agreement has been reached between the countries. A list of countries which have signed such agreements with Canada and with the U.S. appears frequently in *QST*. In addition, most countries do not object to actual emergency radiograms being handled in the amateur bands if government or commercial facilities are not available at the time. Individual amateurs handle radiograms in a number of different ways. Some are "free-lancers" who handle their traffic on individual schedules without recourse to regular nets. Most traffic operators, however, participate in nets of various kinds. The largest organized system of nets is the ARRL National Traffic System. Others include networks organized by individuals for traffic-handling purposes in which individual amateurs participate out of preference.

Originating radiograms

Any amateur can originate a radiogram on behalf of another individual, whether or not this individual is a licensed amateur. It is the responsibility of the originating amateur, however, to see that the message is in proper form before its first transmission because under most circumstances it is improper for a relaying or delivering station to make changes.

Each radiogram originated and handled should contain the following component parts in the order given:

(a) Number
(b) Precedence
(c) Handling instructions
(d) Station of origin
(e) Check
(f) Place of origin
(g) Time filed*
(h) Date
(i) Address
(j) Text
(k) Signature

*Optional with originator.

a) Every radiogram transmitted should bear a number. Keep a sheet with a consecutive list of numbers (beginning with "1") at your operating position. When a radiogram is filed at your station for transmission, complete all parts of the preamble except the number, leaving this blank. When you send the radiogram, assign a number to it from the number sheet, crossing out numbers on the sheet as they are used and making a notation, after the number, of the station to whom the radiogram was sent and the date. Such a system is convenient for quick reference purposes. Most traffic handlers start with number 1 at the beginning of each year.

(b) Every radiogram has a precedence in amateur procedure. This will normally be "Routine" (R). It is a separate part of the preamble and is transmitted as such, not as part of the number. Other precedences are "Emergency" (never abbreviated), "Priority" (P), and "Welfare" (W).

(c) Handling instructions (HX) are available prosigns for use when or if desired by the originator or the originating station, whenever special instructions are required in the handling of the radiogram.

(d) The "station of origin" is the call of the station from which the radiogram was first sent by amateur radio and is included so that handling stations will be able to communicate with the originator if something interferes with the prompt handling or delivery of the message.

(e) The "check" is the number of words and numerals in the text of the radiogram. Handling stations should agree on the check before the message is considered handled. (Full information on checking radiograms will be given later.)

(f) The "place of origin" is the name of the place (city or town) from which the radiogram was started, not necessarily the location of the station of origin. The preamble of a radiogram filed at League headquarters in Newington, Connecticut, might read as follows: NR 457 R W1INF 21 NEWINGTON CT 2057Z JUNE 11.

If a message is sent to your station by mail or otherwise not filed in person, the preamble should show the place the radiogram originally came from. If the radiogram came to League Headquarters by mail from Wiscasset, Maine, the preamble would read: NR 457 R W1INF 21 WISCASSET MAINE 2057Z JUNE 11. Any radiogram received at an amateur station by any means other than amateur radio is an origination when put on an amateur circuit by that station.

(g) The time filed is the time at which the radiogram is received at the station from which it is to be sent. Standard practice is to use UTC. This part of the preamble is optional with the originating station.

(h) The month and the day of the month that the radiogram was filed at the originating station. The year is not included. If the filing time is UTC, be sure that the date agrees.

(i) The address is the name, street and number, city and state of the party to whom the radiogram is being sent. The telephone number should be part of the address. A complete address should always be given to ensure delivery. When accepting a radiogram for origination, this point should be stressed. In transmitting the message by CW, the signal "AA" is used to separate parts of the address, and the address is followed by "BT," or "break," before the text is started.

In street addresses where the words "east," "west," "north, or "south" are part of the address, spell out "the words in full. Suffixes like "th," "nd," "st," etc., are not recommended. Example: "19 W 19th St" should be "19 West 19 St." It is not good practice for the relaying station to change address format, but the originating station should observe the above practices to ensure clarity in retransmission.

(j) The text consists of words in the body of the radiogram. No abbreviations

should be substituted for the words in the text of the radiogram. The text follows the address and is set off from the signature by another "BT".

(k) The signature is usually the name of the person originating the message. The signature follows the "BT" or "break" at the end of the text. The abbreviation "sig" is not transmitted.

After the signature, say "end" or transmit "AR." If there is more to follow, say, "more." On CW, use the prosign "B." If there isn't any more to come, say, "no more." On CW use the prosign "N."

Counting words in radiograms

The amateur radiogram "check" is the count of the number of words in the text only. It is essentially an "as sent" count. While it is assumed that the rules of grammar and spelling will be followed, the check count is determined principally by the spacing used by the transmitting operator in sending the text. Since the first operator to transmit the radiogram is the operator of the originating station who enters the check in the preamble, this check should carry through to the destination. The relaying operator has no authority to change the check unless it is definitely determined that the check as he received it is incorrect, then he should confirm with the transmitting operator before making the change. When such a change is made, the original check should remain in the preamble. Example: An original check of 10 corrected to 9 would be sent "10/9" on CW.

The check is a means of ensuring the accuracy and completeness of your copy. It also indicates to the receiving operator how many words the radiogram he is about to copy will contain. Inclusion of "check" in a message preamble is not optional.

Numbers, ciphers, mixed groups and punctuation each count as one in the check, regardless of length. It is recommended amateur practice not to use punctuation, fractions or other unorthodox or seldom used code symbols in messages as such, but rather to spell these out when used in the text of a message to avoid complications in checking. The letter "X" or "X-ray" is used in place of a period or semicolon and is counted in the check.

Special note: The ARRL-recommended procedure for counting the telephone number in the text of a radiogram is to separate the telephone number into groups, with the area code (if any) counting as one word, the three-digit exchange as one word, and the last four digits as one word. For example, 203 666 1541 counts as three words in the text of a message; 666 1541 counts as two words. Separating the phone number into separate groups also minimizes garbling.

The principle of counting words as sent can be illustrated by a few examples, as follows:

New York City....3 words
NYC.....................1 word
Fifty six..............2 words
527B.....................1 word
H O Townsend....3 words
W1YL/4............. 1 word

A few rules must be observed in sending words so that this principle of "counting as sent" will not be abused:

1) Make your spacing methodical and accurate on both phone and CW.

2) Follow the dictionary wherever possible.

3) Do not waste time in traffic nets arguing about "how to count." The purpose of the "check" in amateur work is to confirm the number of words or groups in the text. "QTB" is a useful signal in confirming check. Once you are sure that you have copied it correctly, "QSL" (on CW) or "roger" (on phone) the radiogram and get on with the next one, correcting the check when you relay the radiogram.

In copying traffic, whether by pencil or typewriter, it is quite easy, with a little practice, to count the words in the text as you copy. When using a pencil, copy five words to a line. At the end of the radiogram, you can readily figure the number of words by the number of lines (plus how many words over) you copied. By typewriter, it is more convenient to copy 10 words to a line, and this can easily be done by copying five words, hitting the space bar twice (instead of once), copying five more words, then line spacing to begin a new 10-word line. At the end of the radiogram, a glance at the number of lines will show you how many words you copied. You can then query the sending operator if your figure does not agree with his.

When traffic is heavy and time is precious, it is not considered advisable practice to query a check unless you have reason to believe that a mistake was made in either sending or copying.

ARL check

Messages containing ARRL numbered radiogram texts (see form FSD - 3) have the same form as any other radiogram, except that the symbol ARL (*not* ARRL) is used before the check. This symbol indicates that a spelled-out number in the text of the radiogram refers to a complete text bearing that number on the ARL list.

In delivering a message with an ARL text, you (of course) deliver the complete text. It is therefore very necessary that the symbol ARL be included with the check to avoid the possibility of delivery of a meaningless number to the addressee.

Use of ARL text is a special tool for special occasions. When used, it should be used properly to avoid delays and confusion.

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92633

Bringing ARDF to your town

"An on-foot foxhunt sounds like a blast! Where's the nearest one?" That's the gist of many responses to my recent columns about world-class radio direction finding (RDF) contests. If the writer is in Scandinavia, northern Europe, or eastern Asia, the answer is easy. This radio sport is popular there and weekly events take place in some cities. But it's still a new concept in North America.

While you can go on a mobile T-hunt every weekend in cities and towns all over the USA, international-style hunting is just beginning to catch on. My best advice is that if you want to go foxhunting, put on a foxhunt or two yourself. Once the sport catches on in your area, you'll have lots of hunts to go on in the future. You may even end up at the World Championships!

Organizing a hunt can be almost as much fun as going on one. April (WA6OPS) and I had the privilege of assisting at international competitions in 1991 and 1993. That made us bold enough to put on two on-foot foxhunts here in southern California. A lot of work went into each one, but everyone agreed they were worthwhile and great fun. From these experiences, I have lots of hints and advice for staging such events.

Photo A. Distinctive awards add class to your fox-tailing contest. April Moell WA6OPS designed this trophy for the overall individual winner of VHF-96.

First, a few words on terminology. "Foxhunting" is a widely-used name for any type of competitive direction finding, particularly international-style on-foot hunts. The term appears to have originated in the late 1940s. Some stateside hams have adopted it to refer to mobile hidden transmitter hunting, too. Unfortunately, non-hams frequently confuse it with the British horse-and-hound sport and get the impression that we are putting defenseless furry animals in jeopardy.

In Japan and China, the terms "fox-teering" and "fox-tailing" are gradually replacing "foxhunting." Swedish hams officially began describing the sport as *Radiopejlorientering* (Radio Direction Finding Orienteering) in 1973. It's accurate, but awkward. Most International Amateur Radio Union (IARU) national member societies have adopted the abbreviation "ARDF" (Amateur Radio Direction Finding), not to be confused with the generic "RDF" abbreviation for any method of finding the source of a radio signal. From now on, "Homing In" will use "fox-tailing" and "ARDF" to refer to international-style on-foot contests and the term "T-hunting" when describing American-style mobile hunts.

Let's get started

Once you have decided to be your town's ARDF huntmaster, your first mission is to become thoroughly familiar with the basics of fox-tailing. If you haven't already, now would be a good time to read "Homing In" from December 1995, January 1996, and April 1996. I also highly recommend the Radiopejlorientering site on the World Wide Web (http://spitfire.ausys.se:8003/hsn/rpo.htp). There you will find basics of the sport, rules, equipment, results, and schedules of worldwide events.

The pages are edited by Hans Sundgren SM5SVM, with input from Lars Nordgren SMØOY and Per-Axel Nordwaeger SMØBGU. These hams hosted the last ARDF World Championships in 1994. Hans recently expanded his site to include lists of other sites and publications related to all forms of competitive RDF. You will even find the topic index of all "Homing In" columns since the beginning in November 1988.

Mobile T-hunts are often put on by one person with simple gear. Sometimes it's as easy as finding a good spot, turning on the T, and seeing who shows up first. On the other hand, a championship foxhunt always takes careful preparation and a small staff of volunteers to be a success, as you will see. The good news is that only one person needs to have a ham ticket. Consider getting help from anyone who likes outdoor activities. For instance, a local orienteering club was a big help in setting up the 1993 Friendship Radiosport Games foxhunt in Victoria, BC, Canada.

If possible, your hunt should be part of a big amateur radio gathering that will expose our sport to mainstream hams. My first fox-tailing experiences were part of the 1991 and 1993 Friendship Radio Sport Games, which were week-long get-togethers of hams from USA, Japan, Russia, and Canada. In addition to the hunt, these Games included CW competitions, DX contesting, and a trip to a hamfest. The hunts April and I headed up have been part of Hamcon-95 and the West Coast VHF/UHF Conference (VHF-96). If possible, make your hunt a sponsored convention activity. This will get you wider publicity, insurance coverage, and maybe enough cash to cover trophies, certificates, prizes, and refreshments.

An informal spur-of-the-moment RDF "treasure hunt" at a hamfest or picnic can be great fun. But it is better to plan ahead and make a "happening" of your event. Lots of advance publicity is a must. This increases your chance of attracting experienced foxhunters and it encourages everyone to make equipment preparations in advance. Put out the word via hamfest flyers, club newsletters, packet bulletins, and local landline BBSs. Follow up with calls to active T-hunters to make sure they attend and encourage them to spread the word. Remind everyone that all family members who have equipment can hunt—a ham license is not required. Make a special effort to contact hams who do amateur radio activities with schools, Scouts, and youth groups.

To increase attendance and promote fox-tailing, encourage local "ham celebrities" to attend and participate in your hunt. Personally invite club presidents, repeater owners, ARRL officials, and hams in the local media. Offer to provide RDF gear to them, if you have it, to get them to go out on the course. At VHF-96, our ARRL Division Director and Vice-Director competed, along with a representative from ARRL Headquarters Laboratory. They were good sports and their presence and publicity drew a bigger crowd.

Hunting for dollars?

Regional and world IARU foxhunting championships are true amateur events. Only medals and certificates are awarded to winners. But I think it's OK to encourage larger attendance by giving cash prizes at your hamfest hunt, if funds are available. At Hamcon-95 we awarded cash and trophies for the first five places in each age division, ranging from $50 for first place to $10 for fifth place. The cash prizes at VHF-96 were smaller, but the trophies were nicer (**Photo A**).

Another way to get a greater turnout is to include a team competition. International championships have gold/silver/bronze awards for individuals in four age categories, plus medals for national teams having the best combined individual scores. At VHF-96, we used this method to create friendly rivalries between clubs. Here is what we announced: "When registering, you may declare yourself to be a member of a team representing your club, city, family, etc. Each team may have a minimum of three and a maximum of five members. Each entrant may be on

only one team. (Or he/she may choose to not be on any team.)

"If a club/city/family has more than five hunters, they must split up into more than one team. A team may include members in more than one age division. Team awards are determined by the best three scores of the team members. Just as in the individual competition, scoring is first by number of foxes found and second by time. Team members may not help one another on the course in any way."

All but one of the VHF-96 hunters joined a team. The rivalries were as fierce as any Field Day club competition. One team even had its own cheerleaders (**Photo B**)!

At regional and world championships, there are always two separate contests on separate days. One is on eighty meters with keyed CW, the other is on two meters with MCW signals. Here in Region 2, all ARDF events have been on only 2s meters, where it is easy to use ordinary handie-talkies to get bearings. Almost every active ham has one, so the pool of potential 2-meter hunters is much larger than for 80 meters. Portable RDF sets for 3.5 MHz can be home-brewed readily and I plan to cover that topic in a future "Homing In," but for now we'll stick to 2 meters.

Finding the right spot

When SMØBGU and his friends chose a site for the last World Championships, they didn't have to look very far. Vast thick forests are plentiful all over Sweden. Its *Allemansratten* (Everyman's Right) principle of law allows citizens free access to any forest or field in the country. Swedish forests are so dense that you sometimes cannot see more than twenty feet in any direction. In an open field, competitors can easily watch one another and will tend to play "follow the leader," but not in a Swedish forest.

City dwellers will find site searching much tougher. Here in southern California, most large parcels of land are barren and arid. Who wants to do ARDF in the desert? For VHF-96, we considered and dismissed the mountains (too far away), the big regional parks (too crowded, admission fees charged) and flood control dam sites (couldn't get permission, liability issues).

We ended up selecting Hillcrest Park in Fullerton. It has lots of elevation changes and enough varieties of flora to be called a botanical park. It's hilly, shady, and close to the convention hotel. The city Parks Department seemed eager to have us and didn't insist on being indemnified as a condition for granting a permit. Hillcrest's only disadvantage is its small size—only 40 acres. While far too small for a world championship, it turned out to be excellent for this group of beginners; not too hard and not too easy.

If your hunt will be in a large forest, good maps are a must. Many European foxhunting champions are also skilled orienteers, insisting on detailed topographical maps with contour lines at 20-foot elevation intervals. Orienteers tell me that only a handful of parks around here have been mapped in this detail, certainly not Hillcrest Park. We ended up making enlarged copies of a 30-year-old map hand-sketched by the Superintendent of Parks. For a 40-acre hunt this was adequate; no one could get lost in a venue of this size. On the other hand, you will want to practice your triangulation skills with better maps if your hunt group is training for the championships.

Do not distribute maps to the hunters until just before the hunt starts. In fact, it is best if the hunt location is kept secret. This prevents competitors from trying to gain an unfair advantage by scouting out the venue, and it minimizes the possibility that hiders will be observed while setting out the foxes. VHF-96 hunters were told to gather at the hotel parking lot at 1 PM Sunday, at which time they were given a sheet with directions to the site.

Photo B. Including a team competition will encourage friendly rivalries and increases attendance at your ARDF event. Lara Garrabrant KD6AYO and Rachael Kent KE6GIO decided to be cheerleaders for the Orange County RACES team at VHF-96.

Do-it-yourself foxboxes

International rules are very strict about transmitter timing. Following these standards will give hunters experience with the timing cycle they will encounter at future international meets. Championship course foxes transmit for exactly 60 seconds each in numbered sequence. There should be no dead air time between fox transmissions and no overlapping of transmissions.

To meet these requirements, you need a set of identical high-stability timers, one per fox. No ready-to-use commercial foxhunting transmitters or controller/timers meeting these requirements are available in the USA at the time of this writing, so warm up the soldering iron. The Friendship Games hunt used home-brewed TBOX controllers designed by Ron Seese N6MBR. Plans are in "Homing In" for October 1991.

Kevin Kelly N6QAB and J. Scott Bovitz N6MI put the TBOX boards, transceivers, and sealed lead-acid batteries into rugged surplus ammunition cans (**Photo C**). TBOX provides CW audio and PTT timing to any 2 meter transmitter. It has crystal-controlled timing, but getting five of them to start up in proper sequence was tricky. A momentary power glitch will cause loss of synchronization.

Photo C. Surplus ammunition cans make excellent waterproof fox enclosures. Kevin Kelly N6QAB is preparing this foxbox for the Friendship Radiosport Games.

Here is another option to consider, though I have not tried it: Use dual-band handhelds for the foxes. The HT in each fox repeats UHF-to-2-meters with subaudible tone (CTCSS) control. Each fox responds to a different CTCSS frequency. A keyer sends MCW audio for each fox in sequence on the UHF control channel. The keyer also changes the UHF transmitter's CTCSS frequency each minute to select which numbered fox repeats the controller's transmission.

This method will give perfect synchronization, but it requires that the UHF control transmitter's signal be solid copy at each fox. Be sure to disable the 2-meters-to-UHF repeat function on each fox so that they do not retransmit each other's signals onto the control channel. If you use this method, or if you are interested in participating in development of advanced fox controllers for IARU-rules hunting, please contact me.

Teach 'em and sign 'em up!

If there are technical forums at your convention, be sure to have one on ARDF. Explain the basic rules, give tips for tracking, and show how to get bearings with a handie-talkie and simple accessories. In addition to the ARDF forum, we put on a "clinic" at VHF-96. Prospective hunters were invited to the hotel parking lot late Saturday afternoon, where

a couple of "easy" foxes had been put out for demonstrations and equipment testing.

Have a prominent sign-up table at the hamfest where people can register for the hunt. Staff it with people who are knowledgeable about ARDF so they can answer questions and encourage everyone to try it. Provide handouts that explain foxhunting and easy on-foot RDF methods. Set a deadline for registration so that you will have sufficient time before the hunt to organize your age divisions, start sequence, etc. Our convention hunts were on Sunday afternoon; the registration deadline was 5 PM Saturday.

OK, you've found a perfect site, built the foxes, spread the word, held a clinic, and registered a bunch of hunters. The hardest part is over. It's time to put out the transmitters, make a starting lineup, run the hunt, tally the scores, and hand out the prizes.

In Part 2 of this series, I'll take you through the process step by step. Meantime, get started on scheduling and site searching for an ARDF event in your own area. Don't forget to send a notice to me. Mail your letters and hunt photos to the address at the beginning of this article. Send E-mail to Homingin@aol.com or 75236.2165@compuserve.com.

The Homing In Web Site isn't quite ready yet, but I have paper copies of my handouts for our recent southern California ARDF events. They are excellent models for your own activities. My handout package includes sample promotional announcements, ARDF information flyers for the sign-up table, teaming information, rules handout for registrants, assembly point instructions, starting lineup/scoring form, and results list. To get the package, send a 6x9-inch self-addressed envelope with 78 cents postage on it (for three ounces) to my post office box. 73

NEVER SAY DIE

radio, which was at that time a fast-growing, largely American hobby which was delivering thousands of engineers, technicians, and scientists into the workplace to support and further the American world leadership in electronics and communications. When Coke bought the idea, Bill put them in touch with the ARRL to implement it. This was going to be the biggest publicity coup for the hobby in history! Millions of people would get to see ham stations in operation and be able to send messages home to their family and friends from the Fair. There would be booklets explaining about ham radio and telling people how they, too, could enjoy this wonderful and educational hobby. Lonely? Not when you can turn on a switch and talk with people anywhere in the world!

The plans for having a dozen or so operating ham stations in a large central exhibit area as the main theme for the Coke exhibit unraveled when word leaked out that in return for a $25,000 donation to the League's Building Fund, the exhibit would use only Hallicrafters equipment. The other manufacturers were outraged. As was Coca-Cola, when they found out. So amateur radio ended up with a small out-of-the-way room up on the second floor of the pavilion, next to the toilets, and only reachable via a small stairway. Instead of millions of visitors seeing amateur radio at work and sending messages for them, it was viewed by hundreds.

Could visiting hams get to operate? Har-de-har. I got a lot of angry letters about that from frustrated hams who'd managed to find the place, but then had to stand outside the little room and look in through a window.

Stu Meyer, the president of Hammarlund, was particularly upset over the sell-out of the hobby by the League, so he

Fix That Scope!

Last time, we began looking at the internal operation of an oscilloscope, with an eye toward fixing a broken one. Let's continue.

More power supply

We began at the power supply, assuming the scope was altogether dead. If you've gotten the supply going again, the scope should be working, if simple supply failure was the original problem. If it promptly died again, figure on a short somewhere, and use standard troubleshooting techniques, such as disconnecting circuits one by one to find the short.

If the supply comes up but the scope still doesn't work right, attack the problem in a logical manner—what *part* of the scope isn't working? If there's nothing on the screen at all, the first place to look is the trigger circuitry. The trigger starts the sweep when the incoming signal crosses a voltage threshold you set with the trigger level knob. If the trigger circuits are not working properly, they may inhibit the beam completely, resulting in what looks like a dead scope! Try setting the trigger for "auto" or "free run" operation. Sometimes, that'll get the beam moving. If you still see nothing, it could be a trigger problem, but most likely isn't. Instead, go back toward the power supply and make sure *all* of the output voltages are really there; sometimes, one of them will be missing or way off.

Dot's nice

If you get a good focused dot on the screen but it won't move, you can assume it is not a high-voltage problem. Is the dot unfocused? Try turning the focus control. If there's no change, something's out in the focus circuit or in the high voltage itself. Most likely, it'll be a diode or a very high-value resistor. Some of those resistors can be in the 10-megohm range or more, making them quite difficult to measure, but if you see a burned one, that's a pretty good indicator of trouble. If there *is* a bad diode, be sure to replace it with a suitable part; a 1N4000-type diode won't work here.

If you can focus the dot, that's a good indicator that the high-voltage section and focus divider network are working fine. Keeping the brightness low (to avoid burning the screen with the non-sweeping dot), try putting a signal into one of the vertical inputs. Just touching the input with your finger ought to do the job. Be sure, of course, that you've set the controls to display that input. If the dot becomes a vertical line, that indicates operation of the vertical section. If nothing happens, even when the vertical attenuator is set for maximum sensitivity, your vertical amplifiers are not working. Or, perhaps, they're not getting all of their required supply voltages.

Sweep me away

If you do get the vertical line, you're getting somewhere! At this point, the big question is why there's no horizontal sweep. Before you assume it's a sweep problem, be absolutely sure you haven't set the horizontal sweep to "external" or "X/Y." Those settings intentionally disable the horizontal sweep, permitting an external signal to drive the beam back and forth. With no signal, there'll be no sweep, even though there's nothing at all wrong with the scope. I would consider this obvious, and wouldn't even mention it, had I not done it myself a couple of times.

As with other problems, sometimes sweep failures can be traced back to the power supply. In fact, that's often the cause. I have one broken scope right now with precisely this problem. The tip-off is that the vertical amps' position controls have to be turned way off-center in order to put the beam on the screen. That suggests that one of the power supply voltages is not there, or is very low, causing one side of the electrostatic deflection to be quite weak, or causing the vertical amps to be very unbalanced. Only the long-awaited schematic will tell for sure.

If the supply voltages are all there but the sweep still won't run, either the horizontal oscillator or the horizontal amplifier isn't working. Unlike the oscillator, the amplifier is easy to check without another scope. Simply inject some other signal into the external or "Y" input, after setting the sweep for "ext" or "X/Y." If there's no horizontal movement of the beam, the trouble is in the amp. If, though, the beam does deflect, then the oscillator isn't working. Although that sounds like an easy fix, it can get tricky, because the oscillator is gated (stopped and started) by the trigger circuits. Separating the two systems (oscillator and trigger) isn't always easy. At this point, you'll need another scope: a DVM just won't get you very far.

Set the broken scope for free run or "auto" trigger, and see if the gating point, as shown on the schematic, changes from the state it's in when the controls are set for "normal" triggering. It may show pulses, or it just may change polarities, depending on the design. For instance, it may go from zero volts to 10 volts, or something like that. If nothing at all happens, chances are the trouble is in the trigger, not the oscillator, and the problem is causing the oscillator to remain gated off. Most trigger circuits are pretty complex, but they boil down to a comparator of some sort and a timing circuit to sync the oscillator. At the end of the chain is some kind of driver chip or transistor which supplies the gating signal to the horizontal oscillator. That driver is where most of the problems I've ever run into have been located.

If you do see the gating signal, but still have no sweep, suspect the oscillator. The horizontal oscillator itself is usually pretty simple. Basically, it's just a sawtooth wave generator, and may be little more than one or two transistors or IC gates. The tricky part about it, though, is that it is connected to a whole bunch of timing caps and/or coils, in order to provide the various sweep rates. These are connected to the big control you turn to select the rate. As with anything that depends on connections, the connections are often the problem. In particular, check the various switches and rotary controls for good contact. Of course, one of the transistors could be bad; I've seen it once or twice. If you replace one, you may have to recalibrate all the timing elements for the different sweep ranges. Yuck! Of course, if you don't need NIST (National Institute of Standards and Technology, previously the National Bureau of Standards) calibration accuracy, you can just match the ranges to what's shown on your borrowed scope.

Kitchen sync

If you have the opposite problem (the sweep runs but never syncs), at least you know the oscillator works! In this case, the trouble is almost certainly in the trigger circuits, most likely in that driver again.

Most scopes provide a locking of the trace when in the "auto" mode, but some don't. I spent a bunch of time trying to figure out why a newly acquired NLS Miniscope wouldn't lock in the "auto" mode, even though it locked fine when in the "internal trigger" mode. Then I called the company and found out there was nothing wrong with my scope; it was designed that way! On this particular model, the "auto" mode is really a free-run setting. So, before you waste many hours, be sure the scope is meant to do what you think it should be doing. Of course, if it used to work and now won't, you already know how it ought to be working.

Hold it

Better scopes have a feature called "delayed sweep," which lets you closely examine various parts of a long waveform, by delaying the start of the sweep by an amount of time you set with the delay knob. Delayed sweep is one of the most useful features on any scope, especially if you work with video signals. Sometimes, the delay circuitry can go out, although it doesn't seem to happen

often. The delay circuit works by intercepting the output of the trigger circuit and delaying it by the amount of time selected. It's basically just a couple of monostable multivibrators ("one-shots"), and isn't too complicated. But, like the horizontal circuit itself, the delay stage is connected to a series of timing elements via various switches and controls. If yours goes out, check those contacts before delving into the circuitry itself.

When using the delayed sweep, you should be able to see various pulses all around the delay circuit. If nothing's moving, something's getting lost somewhere. If the trigger pulse is present on the delay circuit's input, the problem is in the delay itself. If there's nothing coming in, trace back to the trigger circuits and see where the signal disappears.

Well, I think we've covered all of the common problems with oscilloscopes. Now and then, of course, you may run into a weird one that defies logical explanation. Hopefully, though, our exploration has helped you find your scope's failure, and you'll soon be back in business. After all, what would life be like without old faithful?

73 de KB1UM.

NEVER SAY DIE

Continued from page 81

formed a manufacturer's group and went to the other Fair exhibitors, looking for a place to show off amateur radio. He found it with the Venezuelan pavilion, which offered some space on the main floor of their pavillion. This one had ham gear from all of the manufacturers.

In order to get a license for the station they needed a ham club to back it. They found one in New York City that was game. I know you're not going to believe this, but the League fought the ham manufacturer's group all the way. They even got Herb Hoover Jr, the ARRL president, to go to Venezuela to try to convince the president of the country to close down the ham exhibit. Then they tried to get the FCC to close it down due to some claimed irregularities in the sponsoring ham club's election process.

The chap who did most of the leg work on the alternative ham station for the Fair was K2AOE, who got so upset over the ARRL moves to shut the exhibit down that he committed suicide. He took things too seriously.

Amateur radio did get exposure at the Venezuelan pavilion, but nothing like it would have had if we'd been the central feature at Coca-Cola exhibit. Little did the folks at Hallicrafters know that they would be put out of business (along with Hammarlund and just about everyone else in the ham industry) within two years as a results of the ARRL's self-promoting "Incentive Licensing" proposal.

I hope you enjoyed my bit of ham history. I'm sure it will anger the brainwashed who truly believe the League can do no wrong.

QRP

switching arrangement. I did not want to use a rotary switch or relays. I also did not want to move the test leads from one set of jacks to another. I ended up using a 4PDT switch having a center off position. God only knows where this one came from, but a check with several surplus houses should turn up something close. The center off position does exactly what the name implies. It turns the meter off. The meter runs from a 9V battery.

Standard banana jacks are used for the test leads. I always end up losing test leads for the different meters I have, and came real close to hard-wiring them in place.

Radio Shack™ has a slick plastic case with a built-in battery compartment. This made an ideal case to install the meter. I plan to have an engraved plastic panel made to give the project that "commercial" look.

I can now choose between current and voltage with the flip of a switch, without the need to swap test leads. It's accurate enough for me, and rough and tough enough to be kicked around in the toolbox. The meter also makes a great tool to keep on hand for Field Day.

Parts List for Solar Tester

The part numbers are from Hosfelt Electronics™ (1-800 524 6464)

.1 ohm 5 watt 5% power resistors # 47-155

Insulated binding post Red # 80-265

Insulated binding post Black #80-266

Test leads # 52-105

4PDT switch, center off # 51-310

VE Exams by ARRL/VEC. Bring photo ID and one other form of ID, original current license and any CSCE forms applicable, a check or MO made out to ARRL/VEC. For more Exam info, contact *Carl Clark NØKAX, 2145 Delicia Dr., Dubuque IA 52001. Tel. (319) 557-9149.* For Hamfest info, contact *Loren Heber, (319) 556-5755; Jerry Lange, (319) 556-3050; Jerry Ehlers, (319) 583-1016; E-Mail: SHEBER@MWCI.NET;* or *Internet: http://galaxy.mwci.net/grarc/top.htm.* Send payments to *G.R.A.R.C., P.O. Box 546, Dubuque IA 52004.* Talk-in on 147.24/.84 Rptr.

SPECIAL EVENT STATIONS

AUG 3–7

OSHAWA, ONTARIO, CANADA The Ontario Northland "Polar Bear Express" will depart from Cochrane Ont. at about 0800 hours, for its 186 mile journey to Moosonee Ont. in the James Bay lowlands at the southern end of Hudson Bay. An additional passenger car will have several HF stations set up so that DXing can be done en-route. A station will be operated from the train station where part of the group will DX continuously from Aug. 3rd–

Aug. 7th. A second part of the group will head for the water and much sought after IOTA and Canadian Islands. Everyone is invited to come along and have some fun DXing from the train or the station, but you will have to cover all costs for travel, lodging and food. This event is sponsored by the Ontario Northland Railway, Durham Radio, and Alinco. Communications will be in English, Spanish, and Italian. For a rail schedule and round trip fees, call *Ontario Northland at (800) 268-9281*. For updates on the project, visit web page *http://www.durhamradio.ca*. To learn more about joining the expedition, contact Laird Solomon VE3LKS at *(905) 434-7339*; packet *ve3lks@va3bbs*; Internet *lsolomon@osha.igs.net*; *http://www.osha.igs.net/~lsolomon*. To get tourist info on Cochrane, Moosonee, and the surrounding areas, contact *Stephanie Wright at (800) 354-9948*.

AUG 9–10

MIDDLEBOURNE, WV The Tyler County AR Organization will operate KA8GOH from the 34th annual Tyler County Fair, 1400Z–2200Z Aug. 9th and 10th. Freq: Phone portion of General 80 thru 10 meters. For a certificate, send QSL and a 9"x 12" SASE to *TCARO, P.O. Box 287, Middlebourne WV 26149, USA.*

AUG 10–11

MT. DAVIS, PA The Somerset County ARC will operate station KB3BOD from the highest point in Pennsylvania. Operations will begin 1700Z Aug. 10th and end 2000Z Aug. 11th. Listen on the lower 50 kHz of the General class phone. The ARC will also broadcast on the CW bands of 10–80 meters as conditions allow. For a certificate send QSL and SASE to *KB3BOD - SCARC, 708 Casselman St., Confluence PA 15424.*

AUG 11

NEW KENSINGTON, PA Station K3MJW, commemorating the Centennial of the City of Arnold PA, will operate from 1200Z Aug. 10th–0400Z Aug. 11th, on 50.150, the lower portion of General phone; Novice CW on 10, 40, and 80 meters, and Novice phone 28.464. Sponsored by the Skyview Radio Soc. For a certificate, send QSL to *K3MJW, 2335 Turkey Ridge Rd., New Kensington PA 15068, USA.*

AUG 17–18

BATAVIA, NY The Genesee Radio Amateurs Club is pleased to announce their 2nd Annual "Wings of Eagles" Special Event Station, to be held at the 16th Annual "Wings of Eagles Airshow," at the Genesee County Airport in Batavia. Operation will be Aug. 17th and 18th between 1300 UTC–2100 UTC on 40 meters at 7.250 ± 20, and on 20 meters at 14.250 ± 20. For a certificate, send a QSL card and a 9" x 12" SASE to *G.R.A.M., Box 572, Batavia NY 14021-0572 USA.*

ENGLEWOOD, NJ The 37th New Jersey QSO Party will be on the air Aug. 17th 2000 UTC–Aug. 18th 0700 UTC; and Aug. 18th 1300 UTC–Aug. 19th 0200 UTC. Freq.: 3535, 3950, 7035, 7235, 14035, 14285. Portable and mobile operation is encouraged. For rules, SASE to *EARA, Box 528, Englewood NJ 07631 USA. Sponsored by the Englewood ARA, Inc.*

VANCOUVER, WA The Clark County ARC will host an SE Station to help the Northwest Antique Aircraft Club of Vancouver celebrate the annual "fly-in." Operation will be in the lower portion of the General class bands and on 28.450 N/T 10 meter band; plus the 2 meter band, to be announced on the 147.84/.24 W7AIA Rptr. Times: 1500–2300 UTC Sat.; 1500–2200 UTC Sun. For QSL/certificate, SASE to *CCARC, P.O. Box 1424, Vancouver WA 98668 USA.*

AUG 18

SCHAUMBURG, IL The Schaumburg ARC will operate WB9TXO 1300 UTC–2100 UTC to commemorate SARC's 20th Anniversary. They will be operating 40, 20, 15, and 10 meters up 45 kc from the General portion of the band. For a certificate, send an SASE to *Schaumburg ARC, P.O. Box 68251, Schaumburg IL 60168.*

AUG 28–SEP 2

MT. PLEASANT, IA The Mt. Pleasant IA ARC will operate WØMME 28 Aug.–2 Sep., during the Midwest Old Threshers Reunion. Operation will be in the General portion of the 80–10 meter phone bands. Visitors attending can reach the station through club rptrs. on 147.39 MHz (+600) and 444.95 MHz (+5), and are encouraged to visit the ham shack and sign the guest register. For a QSL card, send an SASE to *Dave Schneider WDØENR, 1675 Old Highway 34, Mt. Pleasant IA 52641-9580 USA*. For info, contact *NØFIB* on the Internet: *garymcme@interl.net.*

AUG 31

VINTONDALE, PA KB3BMW will be operated by the Dividing Ridge ARC 12 Noon–6 PM EDT. to commemorate the 150th Anniversary of Eliza Furnace. Freq.: 7.225/.300, and 14.225/.350. For a certificate, write to *DRARC, 199 Bender RD, Apt. #1, Patton PA 16668 USA.* 73

August is *not* expected to be a very good month for HF propagation, as the calendar shows. Poor (P) days are expected to occur during every week except the second. Note the rash of P (Poor) and trending-toward-Poor days each week. For best results, you'll have to try on days marked Fair (F) and Good (G), or trending between them. The remainder might be suitable for gardening, golf, or other outdoor activity. It's even possible that there will be some pretty severe ionospheric disturbances between the 23rd and 25th, so keep a sharp eye and ear tuned to weather lookouts on that weekend, as well.

An intriguing possibility that often accompanies those days marked "P" and "VP" is that when conditions are generally sluggish, these days can be followed by exceptionally *good* propagation, so be sure to check your favorite bands often and monitor WWV at 18 minutes following every hour surrounding those particular days.

Listen for forecasts with improving solar flux (higher numbers) and decreasing "A" and "K" indexes, which are indicators of magnetic field conditions and absorption of signals. Good luck with your DXing.

AUGUST 1996

SUN	MON	TUE	WED	THU	FRI	SAT
				1 P	2 P-F	3 F
4 F	5 F-G	6 G	7 G	8 G-F	9 F	10 F-G
11 G	12 G-F	13 F-P	14 P	15 P	16 P-F	17 F
18 F-G	19 G	20 G-F	21 F	22 F-P	23 P	24 VP
25 VP-P	26 P-F	27 F-P	28 P	29 P-F	30 F	31 F-G

10–12 meters

This is a daylight-only band this month, but may present openings to tropical areas as well as short-skip openings on the best days (G). During intense sporadic E conditions (rare this month), bursts of strong signals can come and go unexpectedly. Stay alert.

15–17 meters

These bands could stay open into early evening hours with possibilities of trans-equatorial DX on Good (G) days and evenings. Signals seem to peak toward the west during afternoon and evening hours. Short-skip to 1,000 miles or so should be available on many days.

20 meters

This should be your main choice for DX-chasing. Because some areas of the world are dark and others are in daylight at the same time, you can expect dawn-to-dusk, and even later, DX opportunities on Good (G) days/nights. Short-skip will prevail to about 2,000 miles during the day, and farther at night.

30–40 meters

You may find these bands quite noisy (QRN) during the daytime due to the onset of thunderstorms this month, but they will be quieter during the nighttime hours. DX to your east will be the best before midnight, and best to your west before dawn. Choose Good (G) days for the best chances of scoring a new country. Short-skip of 100-1,000 miles during the day, and 500-2,000 miles or so at night, will prevail.

80 meters

You may find that 80 meters will provide DX on Good (G) nights, limited by thunderstorm activity. It may also provide short-skip openings of 200 miles or so during the day and 2,000 miles or more after dark.

160 meters

There will be *no* daytime openings here, due to a high absorption of signals, but it ought to provide skip to 1,000 miles or so after dark. Only rarely will you find DX, and only on Good (G) nights with low or no thunderstorm activity. Low-frequency static bursts, hundreds of miles in length, limit your summer operations. 73

Hey, That's Bribery!

Yeah, I know. But I want to see what's going on with your club, so if your club secretary will put me on the list for a club newsletter, I'll swap a complimentary one-year *73* subscription ($25 value) you can raffle off at the next meeting. Or use as a prize. Please address the newsletter to Editor, *73 Magazine*, 70 North 202, Peterborough NH 03458-1107. I'll also need the secretary's address so I'll know where to send the prize subscription certificate.

What am I looking for? I want to see news of new hams being elmered and licensed. And that the club is backing a member in a run for the state legislature so we'll start having some political clout and not get clobbered every time a tower restriction is proposed. I want to know if your club is giving any technical sesions on different ham modes such as packet, satellites, SSTV, and so on. I want to know about any special club activities such as hamfests, auctions, and so on. I'm always looking for good articles that have appeared first in club newsletters.

Wayne

HAM HELP

We are happy to provide Ham Help free on a space-available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double-spaced, on a full 8-1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully. A 1, for example, can be misread as the letters l, i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

WANTED: Software for the YAESU 747 Computer Controller. Please reply to Robert Hall KC7FRY, 5314 East Linden Place, Tucson AZ 85712.

Does anyone know the address of JBI Products and Technologies? Please contact Robert Hall KC7FRY, 5314 East Linden Place, Tucson AZ 85712, and/or Joyce Sawtelle, (603) 924-0058. Thank you.

WANTED: QSLs. I took part in the WPX-contest last weekend using the signal J45DZX. Please send the QSLs to Goran Lundell SMØCMH, ELGOVAGEN 11, S-133 36 SALTSJOBADEN, SWEDEN, or via the Swedish QSL-bureau SSA.

UPDATES

Simple Parts List Omission

In the May 1996 issue, on page 41, there was an omission in the Parts List of "Simple Multi-Use Amplified Speaker." The list should have also included:

C8 .1µF

C8 does appear correctly in the schematic diagram.

No, the *other* right

Also in the May issue, a sharp-eyed reader, Jim Farago, pointed out to us that in "Carr's Corner" on page 80, the integrator/voltage doubler is drawn incorrectly. C1 is drawn backwards in polarity and should connect as shown in the unrelated article on page 78 ("Antenna Noise Bridge Detector"): to the junction of D1 cathode and D2 anode.

U2s have a way of vanishing

In June's "Simple Inductance Meter," on page 57, **U2**, a 78LØ5 5 volt regulator, is missing from the Parts List. We regret any confusion this may have caused.

NEVER SAY DIE

Wayne Green W2NSD/1

Debacle?

I'm sure you're not going to believe that the ARRL plan to bury the Industry Working Group 2A (IWG-2A) of the 1997 World Administrative Radio Conference (WARC) in letters and E-mail from ARRL members has boomeranged, making what was a serious situation infinitely worse.

The League might have taken a hint when their initial pressures and threats were rebuffed by the IWG. But no, if a little pressure and threats don't work, let's escalate the attack. The predictable result is a very angry working group, one which is going to be even less willing to sit down and reasonably discuss the situation.

This all has to do with the potential loss of the 144 and 420 MHz bands to commercial development, as you probably know.

There is just an almost-minuscule possibility that the IW Group may suspect that the League is playing with a very weak hand. Other than rallying the blindly loyal members to send letters and E-mail, the League has few weapons for this battle they've chosen to pursue. Negotiation might have been a better tack.

The sharks in Congress have tasted blood and are eager to push for the sale of as much of the spectrum as possible. And guess which group has one of the biggest spectrum allotments? Make a second guess as to which group has the least lobbying power? Want to try for a third? Guess which group is providing the least in the way of benefits to the public in return for their use of billions of dollars of spectrum?

I see a gaping hole in human reasoning which is working to our disadvantage. Few of us seem to have any sense of the future. Most of us are so totally wrapped up in the present and past that the future, as far as we're concerned, is totally in God's hands, not ours. So we're using up the world's resources of metals, oil, coal, natural gas, and so on, and who really cares about the mess we're leaving our grandchildren? We're eating fast-food crud, drinking poisoned water, breathing air that is killing trees, and thus substantially shortening our lives. And we hams are using about 3% of our allocated radio spectrum to have fun, and little more.

Sure, rag-chewing is fun. And DX pileups are a challenge for the combative. A handful of hams are adventurous, having fun with packet, the ham satellites, SSTV, DXpeditioning, and stuff like that. Maybe 2%. The rest are along for the ride, at least until the music stops. Tomorrow? Har-de-har.

I'm still looking at every ham club newsletter that comes in, hoping to find some mention that the club is holding tech sessions to help the youngsters understand radio and electronics. I'm not finding anything.

So, go right ahead with the ARRL plan and dump on the IW Group, making them even angrier and more likely to show us who's boss. The head of the group was contacted recently on the phone. His response was unprintable. The fate of our two major Tech bands is in the group's hands, so we're busy poking him and the other the group members with a pointed stick.

The loss of 2m and 70cm could, I suspect, just about wipe out the ham industry. Again. It was 30 years ago that the ARRL wiped out the whole ham industry with a really stupid attempt to generate some controversy in order to sell more magazines. The result of this unbelievable miscalculation was that 85% of the ham radio stores went out of business within a year, and over 90% of the manufacturers blew away. Where will our hobby be if we wipe out the dealers and manufacturers again? And there's nothing like 100,000 Techs trying to sell their ham gear for anything they can get, to kill the industry. The Generals did that 30 years ago when threatened by the ARRL with the loss of their HF voice bands, and the American ham industry has never recovered.

The CB industry never recovered from their expansion to 40 channels. CB was growing like crazy, supported by movies and hit songs, and endless PR. Then, in a matter of weeks, it was dead, and most of the manufacturers were blown away.

Sneaky Plan?

A West Coast Chicken Little correspondent has suggested that the hornet's-nest reaction of the IW Group is exactly what the League planned. He points out that the ARRL opposed both the Novice and Tech licenses, and has never considered either to be real hams. Real amateur radio is the HF bands, with ARRL traffic handling nets and CW DXing. By getting rid of the 144 and 450 bands, the hobby would be purified and get back to more like the way it used to be. Remember, he points out, the League has never done anything much to help promote repeaters. That was all done by *73*.

That's an interesting concept, but I've never seen any signs of the League directors thinking two steps ahead, so I doubt the sky is starting to fall now.

Tampa, November 23rd

Are you going to be with me as I try to cram about 10 hours of information into a two-hour time slot? Please write and let me know what you'd like me to cover, because, left to my own devices, I'll deal with amateur radio: its past, present, and future. Then, if there's any interest, I'll explain the secret for making money and the shortcuts for doing it. I've lectured on this at several universities (like Yale, RPI, BU, Case Western, etc.).

Or you may be interested in the incredible developments in *cold fusion* and the opportunities that presents.

Maybe I'll explain some of the amazing things I've found out about how to keep your family healthy so they can knock our stupid Social Security tax system for a loop by living to over 100 in good health.

Education, tuitionless colleges, downsizing the government—there are lots of interesting things I can cover, if you want.

Or perhaps you'd prefer I stick 100% to amateur radio, explaining some of the ways hams win ARRL contests and awards by cheating. How about DXpeditions which weren't in the countries they said they were? I can name and give details on a bunch of those.

In the 1970s there were all kinds of opportunities to get in on the cellular telephone explosion. Then came microcomputers. Ken Olsen, the president of Digital Equipment, said in 1977, "There is no reason for any individuals to have a computer in *their home.*" Two years earlier I was predicting in my editorials that the personal computer would one day be one of the largest industries in the world. The chairmen of Data General, Radio Shack, Wang, and Centronics all told me I was wrong. So did the chairman of TI. But my crystal ball hasn't failed yet. So what do I see as coming down the pike in communications developments? Just ask at Tampa.

Maybe you'd like to hear about my plan for getting hams into our state legislatures so we'll have some political clout. I think any ham club that really wants to can get a member elected. We don't want to be like the unhappy workers who find themselves suddenly out of work when their jobs are moved to Mexico. Unless we take the bull by the horns and run with it we're likely to find our ham bands have moved to Afghanistan.

Continued on page 9

LETTERS

From the Ham Shack

Marc Yuen N6APJ. I want to let you know that your "Never Say Die" column is the best part of the magazine. I've especially appreciated your comments on health and diet. I'm also a subscriber to *Cold Fusion* and am very interested in that field. Please continue with similar content in future issues. You might even recycle some 10-year-old ones.

I suffered a detached retina in my left eye in 1994 and a year later in my right eye. Now I'm up to eight surgeries between the two eyes. Recently, I found *The Healing Power of Herbs* by Michael Murray, ND, ISBN 1-5595-8700-8. I took the recommended herb and my sight has improved to better than 20/70 from 20/200.

I'm interested in seeing construction articles about things like adapting a TV tuner module for a spectrum analyzer, radio astronomy, environmental monitoring such as seismology and weather data collection via packet radio, and such. Lately I've been too busy to pursue hobby activities, but my work is rewarding (the hardware I'm building is going to Saturn).

Well, I'm glad somebody likes my columns... Wayne.

Terry Schieler NØDFH. My friend Larry Junstrum KN4UB should be on your "famous ham" list. He's the bass player for the popular rock group ".38 Special" and a strong spokesman for amateur radio. His phonetics are "Known Nationally 4 Ultimate Bass."

Rudy Ault Jr. N2JZK. Per your list of famous hams, you forgot to include W2NSD/1—Wayne Green: educator, entrepreneur, pioneer, and man of letters. Most of the folks you listed haven't done half as much as you have. Keep up the good work.

Rudy, I'm not famous, just persistent. But amateur radio sure has provided me with a life of adventure... Wayne.

Antonio Anzevino WB2KDE. I just wanted to make a few comments about your editorial and get that list of the books you recommend. You know, at first I thought you were an old windbag, so I didn't bother to read your column. One evening I didn't have anything to read, so I reluctantly picked it up. The first book you mentioned was *The Cancer Cure That Worked.* I found this was a great book and, since then, have bought several other books you've suggested. All have been great.

I'm not the type to be idle, so I build things. Lotsa things. For instance, I have a good idea for a gadget which is really needed. I started off by contacting American manufacturers for parts in order to build a prototype. My patent attorney said to "go for it." Sad to say, I think I know one of the reasons the American economy is going down the tubes. Now I'll try and contact Asian manufacturers for the needed parts. That's more jobs that won't be available in this country.

I'm very much interested in your *Making Money*, though I really don't need to make a million since I'm comfortably retired. It's just that your column has pushed me a bit further than I normally would have gone.

I'd also like you to know that I now read your column as soon as the magazine arrives. I no longer think of you as a windbag, but as a down-to-earth guy who uses his "noodle." Thanks for pushing me into a more constructive attitude.

Glad you're enjoying, Antonio. Yep, we've not only lost our consumer electronics industry to Japan, but we no longer make the parts either. Worse, we no longer make the machines to make the parts. Heck, we no longer make most of the tools to make the machines to make the parts... Wayne.

Dan Sealy AA7OA. That Andy Griffith listed in the June issue isn't the actor, he's 20 years too young. You might want to list Paul Tibbets K4ZVZ, who was the pilot of the *Enola Gay* when it dropped the bomb on Hiroshima. And Jacob Beser W3NOD, who was the electronics specialist on that trip. Then there's Emory Gordy Jr., the OM of Patti Loveless, the singer.

I didn't see how Griffith could possibly have had time for hamming, so that makes sense... Wayne.

George Piatt N1UUN. I would like to take a moment to comment on the code requirement for General, Advanced, and Extra Class licenses. In view of the recent actions by the FCC to rescind the requirement for Morse code equipment on oceangoing commercial vessels and of the fact that the Coast Guard is no longer standing radio watch for CW communications, I think it is time for the ARRL to recognize that CW has passed its time as an essential method of communication. I will agree that CW on the HF bands will get through when QRM and QRN make other forms of communication unreadable. I will also agree that CW is an art form and a tradition of our hobby. But to set the code requirement up as a road block to the high frequency band is no longer acceptable. Fundamentally, it just amounts to "hazing."

I have no problem with making the tests more technically demanding, nor do I have any quarrel with reserving certain portions of the HF bands for CW communications, as we do now for packet and repeater modes in the VHF and UHF portions of the spectrum. My dissatisfaction derives from the exclusion of qualified technicians from the HF bands simply because they refuse to learn a language that is slow and becoming increasingly obsolete.

It must be recognized at some point that the code requirement is preventing otherwise qualified and interested amateurs from advancing in our hobby. Indeed, as time for recreation becomes more difficult to find, can we afford to demand that it be spent learning a language few people are listening to?

Troublemaker... Wayne

Jim Carson WK2K. I am writing about an article on page 90 of the June issue of *QST*, which has me deeply concerned regarding the survival of the hobby into the 21st century, as well as a secondary issue about a long-standing problem of 40m band allocations.

First, let me introduce myself briefly. I was first licensed as WV2OYY in 1960. I upgraded to General, and through the activities of an Elmer, WA2KQG, became very active in CW and phone traffic nets. It was a wonderful experience as a high school student to deliver messages from such places as the Great Lakes Naval Training Center in Michigan. After a brief lapse, I resumed the hobby in 1970 as an Extra with a home-brew SSB HF station. I am an active VE and have taught several licensing classes. One of the classes was a Tech-to-General upgrade done on 2m. My son is N2PNA. While I don't have the time or resources to pursue the hobby as much as I would like to now, I occasionally use my vintage HQ170 and Viking II. (Yes, I can still do 20 wpm.) The future of the hobby is very important to me.

I think the ARRL has done some fine work; for example, the new bands at 10, 18, and 24 MHz. I am concerned that as a group we as hams may miss an important paradigm shift and go the way of the dinosaurs, if we miss our last chance to adapt.

It is my observation that the Morse code is decreasing in relevance to the future of the hobby. It further seems unbalanced because so much emphasis in license testing is placed on this one operating mode. If this much weight was placed on another less-used mode, say, satellite communications, video, or packet, I can imagine the protest that would result. Voice transmission is the mode of choice of the majority of hams, especially if you include the bands above 30 MHz. This could change if voice evolves as a spread-spectrum or a digital mode. It is important that we adapt to the rapid changes in technology; this is not to deny the right of other hams to enjoy the "antique" modes of AM or CW if they are interested in building simple equipment. Further, considering "rights," I do not think

QRX . . .

Pitcaim island Honors Hams

The Pitcairn Island Postal Administration has announced the issuance of amateur radio stamps in honor of the role played by amateur radio operators toward the betterment of the island. Pitcairn Island, with a total of 55 people—12 of whom are licensed hams—has its own post office and postal stamp issues. The British government designs and prints the stamps, and a substantial part of the tiny (1 mile by 2 miles) island's income is derived from the sale of these stamp issues to collectors worldwide.

Pitcairn's first licensed radio amateur was Andrew Young VR6AY. Andrew's first exposure to amateur radio began back in 1922 with a Marconi crystal receiver and a simple spark transmitter that was often used to communicate with passing ships. Over the years, Pitcairn's only communications station grew as technology improved and as ham radio friends from the outside world contributed the much-needed equipment. The operators on Pitcairn have utilized amateur radio for emergency medical advice, as well as for memorable QSOs with friends around the globe, over those intervening years.

A release date of September 4, 1996, has been set for the amateur radio series, with 20 cent and $2.50 stamps, and a two-part $1.50 stamp with a price of $3.00. First Day Covers with all four stamps and the Adamstown, Pitcaim, day-of-issue cancellation are $6.20. For further information or to order the special amateur radio stamp issue, contact:

The Office of the Government of Pitcairn
(Postal Administration)
British Consulate-General
Private Bag 92014
Auckland, New Zealand

TNX Dave Miller NZ9E.

Milton Chaffee W1EFW Silent Key

Milton Chaffee W1EFW, who has been a valued member of the amateur radio community throughout most of his 83 years, became a Silent Key this past March. He dedicated his life not only to the betterment of amateur radio, but also to the prosperity of his country and community. He started his service in the Civil Air Patrol in 1942 raising to the rank of Tech Sergeant in four years. He later lent his administrative talents to councils such as his local housing authority, Chamber of Commerce, the ARRL (where he was director for seven years and Section Traffic Manager for Connecticut), and the QCWA. In addition, he held the position of ARNS treasurer for some time.

Mr. Chaffee was a man whose involvement in the world of amateur radio will serve as an example and an inspiration to hams everywhere. He will be missed by all those who knew him.

Thanks to ARNS Bulletin June 1996 for this information.

No "Hams with Class" in September *73*

This month "Hams With Class" will not appear in *73 Amateur Radio Today*. Carole Perry WB2MGP, the column's author, was not available due to a death in her family. All of us here at *73* send our warmest regards and deepest sympathy to Carole and her loved ones.

Was It Something We SETI?

Did you catch the blockbuster movie "Independence Day" yet? When the evil aliens are poised to annihilate the planet, who mobilizes for worldwide defense? Hams, of course, and with Morse code, yet. And, for those 18 people out there who still haven't seen the movie, yes, we won!

Ham Radio: Not Yet an Olympic Event

The chairman of the Olympic Broadcast Frequency Coordination Committee has announced that hand-held ham radios and scanners will be prohibited at Olympic events because of the possibility of their interfering with wireless microphones and/or live news broadcasts.

Cellular phones, though, will be allowed (as requested by the FCC) and exceptions to the ham rig ban could be made if "appropriate officials request them."

From *Newsline*; Newsline #977.

What Some Guys Will Do for a Free Beer—or K2UDP Likes His Toast Plain ... No Jam, Please

The place: Tampa.

The time: sometime between 12:00 a.m. and 11:55 p.m., May 8, 1996.

The crime: foul-mouthery over the airways and interference with emergency communications.

The motive for risking apprehension: a bottle of beer.

Two jammers for the Tampa area were taken into custody this May (one for drunk driving and one for questioning regarding interference with emergency transmissions) after operator Jim K2UDP, with the help of fellow club members, talked to them on his repeater and invited them to meet him in a bar for a beer.

After tempting the jammers by offering to sell them a stolen rig, Jim "went out to his car" and called the police, who were already looking for the jammers.

During conversations that Jim had with the jammer called Kevin, Kevin confided to Jim that he thought that amateur radio was dangerous and that "My mother didn't raise stupid kids."

At this time, the radio confiscated from the jammers is being handed over to the FCC for RF comparison with the transmissions recorded by bay area repeaters.

TNX *Newsline*; Newsline #978.

FCC License Figures

According to FCC figures, the numbers of new hams and of hams who have changed their class of licenses is up compared to the last half of 1995.

New hams for the months of January, March, and April have each totaled more than 3,000, and upgrades have topped 1,200. In February, new hams numbered 2,109, and there were 980 upgrades. During the last half of 1995, which included the Federal government furlough through the last half of December, the number of new hams averaged 2,137 per month, while upgrades averaged 811 per month. ©1996 *Amateur Radio Newsline*, from *PARKing Ticket*, newsletter of Plano Amateur Radio Klub.

Locust Grove

In 1847, Samuel F. B. Morse wrote to his brother, describing the property he'd just purchased in Poughkeepsie, New York, as unequaled in beauty and constantly changing charm. Locust Grove, Morse's estate, was to be his country home until his death in 1872. In 1901 the property was bought by the Young family, and in 1975 Annette Inglis Young endowed a trust in perpetuity to maintain Locust Grove as an historic site and wildlife sanctuary.

Today, Locust Grove is a designated National Historic Landmark, and is open to the public May 1 to November 1, Wednesday through Monday, 10 am to 4 pm. The 150-acre estate lies along a bluff above the Hudson river, with view of the Fishkill Mountains to the south and the Catskills to the north, and includes historic gardens and buildings, acres of woods and scenic walking trails to the river.

The house contains a collection of 18th and 19th century furnishings belonging to the Young family, but the main point of interest for Morse enthusiasts is the Morse collection, comprising Morse memorabilia, a model of Morse's first telegraph, and a collection of early telegraph equipment.

Morse had a telegraph line wired into his office from the main route close by, and the sound of code can still be heard at his country home. Each year, Locust Grove holds a Telegraph Weekend, during which members of the Morse Telegraph Club use authentic equipment and American Morse for a transcontinental celebration of Morse's invention; while the Poughkeepsie Amateur Radio Club operates a Special Event radio station to demonstrate International code. For more information about the Samuel F. B. Morse Historic House and Grounds, and the many events scheduled there, radio-related or not, contact Locust Grove, 370 South Road, P.O. Box 1649, Poughkeepsie NY 12601-5234; telephone (914) 454-4500.

From *Morsum Magnificat*, June 1996.

NEVER SAY DIE

Continued from page 4

Or maybe you're interested in what's going on with cold fusion and how this amazing phenomenon has forced physicists to rethink the structure of the atom. Or maybe not. Okay then, how about a recipe for some fabulous-tasting, healthy veggie dip? You'll love my "hurry-curry"—a delicious curried chicken dinner in 15 minutes.

When you write, please put "Tampa" on the left side of the envelope so I won't get it mixed with the stack of orders for my booklets which have resulted from my radio interviews. We've had to get an industrial-strength copier just to keep up with the booklet demand. It's a combination mimeograph machine and photo copier.

I'm really looking forward to the ARRL Convention at Tampa in November (23rd-24th). I particularly want to thank ARRL Director Frank Butler for his enthusiastic support, despite word from HQ that my speaking at the convention would "be inappropriate."

Dayton Bombed?

Like most (all?) other hamfests, the HamVention attendance dropped this year. And this despite the increasing emphasis on computers, which seem like they are edging out the ham exhibitors. Well, that's where the money is these days. Maybe you've noticed that some of our major ham manufacturers have cut way down on their advertising. I've noticed. But then, I'm oddly sensitive to that sort of stuff.

Can Dayton be revived? Or is it likely to go the way of NCC, CES, and other formerly mammoth shows? No, I doubt it's the new date, or any of the other excuses the HamVention Committee is using to avoid serious introspection. Our hobby has changed. It's changed a lot! With over half our hams these days essentially confined to 2m and now justifiably fearful of losing their band, the interest in special aspects of the hobby which brought many to Dayton in the past has dropped. We're seeing a drop in interest in SSTV, RTTY, moonbounce, ham satellites, and so on. It was the yearly gathering of such special interest groups which helped keep the HamVention growing for so many years.

Now, with our ranks aging, withering, and shrinking, the youthful enthusiasm which was behind the Dayton trek has dimmed. I saw few youngsters there last year. When I first started going to Dayton in 1955 the hotel was overrun with young hams. These days I have to dodge electric wheelchairs and not trip over walkers.

A side note: I've been surprised when I've talked to many of these doddering wrecks to find that they are years younger than I. Heck, I haven't done nearly as much as I could to take care of my body, but obviously I've done a lot better than most. But, you know, when I bring this up in my editorial, I get hostile letters from the crotchety old men who most need to start rebuilding their almost-destroyed bodies. Figures.

Anyway, back to Dayton. Maybe it's time to start trying some creative ideas to help bring the HamVention out of the 1930s, where it's frozen, and into the '90s. I've proposed several ideas in the past, but they've all fallen on blind eyes.

One problem for many hamfests is that they are almost all organized by hams with little experience in show business. Or even business, for that matter. They don't know how to deal with the marketing challenge. They don't know how or where to advertise, get PR (despite the availability of my admittedly superb video on the subject), attract exhibitors, and so on. None of these skills are intuitive, but it's a pity that our hobby has to bear the brunt of hamfest officials learning what they should already have known at the hobby's expense. Hamfests could be used to help recruit young newcomers. They aren't.

Hamfests *are* show business. They need stars. They need controversy. They need hoopla.

The Amateur's Guide to "Free Energy" Devices

A history, and hints for further experimentation.

Thomas M. Miller WA8YKN
314 South 9th Street
Richmond IN 47374

Any scientist will tell you that "free energy" is impossible. The law of conservation of energy forbids any device that produces more energy than it consumes. To make matters worse, the laws of thermodynamics insist that every device has loss, so no machine can produce *as much* energy as it consumes. Some is always radiated away as heat. It's impossible to break even!

"When an elderly and respected scientist says that something is possible, he is almost certainly right. When he says that something is impossible, he is very probably wrong."

Arthur C. Clarke's First Law

"Imagine that we live in a world where it rains soup, and we all have forks."

Over the years, a number of inventors have come forward with devices which seem to produce more energy than is required to drive them. Most scientists refuse to even examine these devices, and are quick to label the inventors as either lunatics or frauds. Were they to look, however, they might be surprised to find that we are not dealing with propeller-heads and con men. In fact, some of the inventors are physicists, professors, and experienced engineers, well respected (or at least *formerly* respected) in their field. But how can we believe even professionals of this caliber when their inventions violate the most sacred laws of physics?

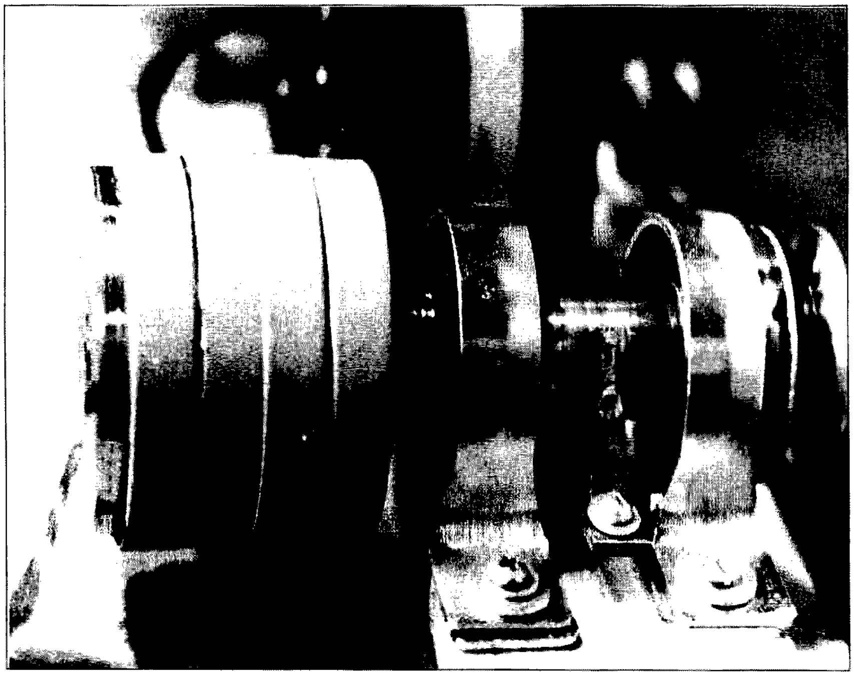

Fig. 1. Extracting free energy from ocean waves. Nature is in constant motion, providing many sources of energy free for the taking.

The truth is that these "sacred laws" only apply to a closed system. There is nothing to prevent a device from extracting energy from another source, even an *unknown* source. None of the inventors claim that their devices create energy. They just tap some energy potential in the environment.

If we can believe some disturbing rumors, some free energy researchers have experienced more than criticism and ridicule. Engineer Robert Adams claims that his patent application was denied and his invention classified under a "Military Use" clause. Not only was his device suppressed for over 20 years, but he was harassed and his life threatened! While this may be hard to believe, there are *trillions* of dollars at stake, and all the political and social power that such incredible wealth represents—certainly a motive for those interested in maintaining the status quo.

Even though many experimenters are understandably secretive about their inventions, a number of so-called free

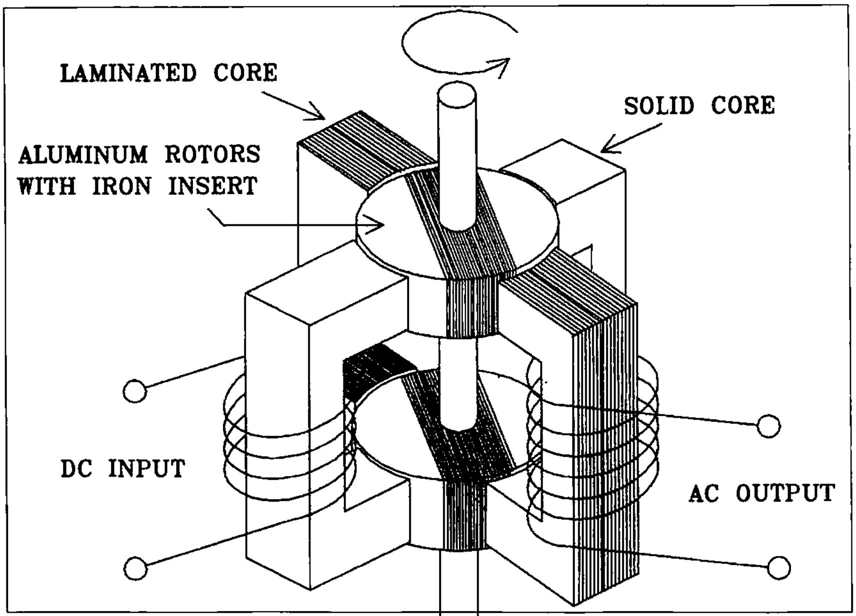

Fig. 2. The variable reluctance alternator, invented by Paul Brown, uses flux switching to convert DC to AC.

energy devices involve well-known, even patented, principles. Many of these are fairly simple, and a talented amateur with some basic electrical and mechanical skills can easily build and experiment with them. Amateur radio operators, being an intelligent and curious bunch, are in a perfect position to study these devices, and to validate or refute the free energy claims.

The universe ... a free lunch?

We cannot "create" energy. The universe *is* energy. What we perceive as solid matter is nothing more than the interaction of energy fields. Not only can there never be an "energy shortage," but there is *nothing else but energy*. All we have to do is tap it and put it to use. Unfortunately, we don't. We allow others to extract this energy and sell it to us. We meekly accept their contention that energy is very expensive to produce, and we even allow ourselves to become totally dependent upon them for our survival. The government is always planning new ways to tax energy, although when the president says that he'll tax our BTUs, you may have to rearrange the letters to discover his true intent.

Imagine that we live in a world where it rains soup, and we all have forks. A few enterprising people learn to collect this soup, refine it, and process it into bite-sized chunks. They then sell it and become very wealthy and powerful. There are always rumors of something called a "spoon," but those who know the most about soup (the soup collectors) assure us that no such thing can exist. There is, after all, no free lunch!

The truth is that the universe *is* a free lunch. Nature is in constant motion, conveniently arranged in perpetual cycles. From the twice-daily rise and fall of the tides to the constant motion of every molecule of matter, all can provide energy free for the taking.

"Even Tesla, the man who harnessed Niagara Falls, could not understand the operation of the unipolar generator."

All natural cycles have a "positive" and a "negative" portion, oscillating around a null, or zero point. For example, ocean waves exhibit crests and troughs, each time passing like a sine wave through the null point. Averaging all the waves produces zero—sea level—yet the momentary fluctuations above and below this point represent usable energy.

Fig. 1 shows a method of extracting energy from ocean waves, converting it into electricity. Such a system could just as easily operate a reciprocating pump, or do other useful work. This is a true free energy system which produces far more energy than it consumes ... free energy, not created, but extracted from the environment.

Some inventors of free energy devices claim to be able to tap the zero-point energy fluctuations in a different sort of ocean—the limitless sea of energy that underlies the universe itself.

"Zero-point" energy and the quantum field

"The only way of finding the limits of the possible is by going beyond them to the impossible."
Clarke's Second Law

A few hundred years ago, scientists accepted the existence of the "ether," an invisible medium through which waves of electromagnetic and gravitational energy moved. The ether coupled cause and effect across distances and explained wave propagation, as they observed it. Scientists expended a great deal of time and effort trying to prove the existence of ether by attempting to measure the movement of the Earth through it, but none were successful. Eventually, they decided that there was no ether, and that space was just that ... nothing at all. Electromagnetic waves moved through the void because, well ... they just did, that's all!

Today, scientists believe that the void is actually a set of energy fields which interact to form a sea of randomly fluctuating energy. Whenever this energy reaches a certain intensity, a particle of matter appears. Actually, two particles appear, one of matter and the other antimatter, since the law of conservation of energy requires that the books always balance. Usually, these particles only exist for the briefest moment before combining to release the energy that went into making them, and the cycle continues. It is interesting to note that, however intense the energy field of any single point at any given instant, the *overall* energy *cancels*. Everything, averaged together, equals nothing. Yet, just as with ocean waves, the local fluctuations of field intensity represent real, usable energy ... enough energy to create a universe.

Is it possible that these free energy devices actually tap into the ultimate source? Perhaps. Apparent violations of

accepted physical laws often lead to opportunities to expand our knowledge of the universe. Just as "relativity" replaced Newton's laws of motion, Maxwell's theories are slowly being superseded by a new electrodynamics based in quantum mechanics. So, until someone invents the science of "Relativistic Thermoquantum Electromagnetic Dynamics," we will have to do what Faraday and Tesla did—build our own hardware, experiment, observe, and make it up as we go along.

Lenzian loopholes?

"Any sufficiently advanced technology is indistinguishable from magic."
Clarke's Third Law

All conventional electric generators require power to drive them, and this driving power is always considerably greater than the total output of the generator. In other words, there is a net loss of energy. Some of this energy is lost through friction in the bearings and drive coupling, and in atmospheric drag against the spinning armature. Some waste heat is produced by current flowing through the windings and brushes, which may have several ohms of resistance. Iron cores also have resistance, and eddy currents will therefore contribute to radiated heat. Even so, the sum of all these losses represents a negligible amount of waste energy compared to the output of a normal generator. Were these thermodynamic losses all we had to contend with, electrical generation would be essentially free.

Sadly, there is another factor to consider. When we rotate the armature of a generator we cause current to flow in the windings. This current, as it flows, must create a magnetic field. The problem is an electrical principle called "Lenz's law." This law states that the magnetic field created by the flow of current will always oppose the field that created the current flow. In other words, if we drive a generator clockwise, the generated current will create a magnetic field which will try to drive the generator counterclockwise. The harder we push, the harder it will resist.

"New technology has the disturbing habit of making the impossible suddenly commonplace."

You can feel this effect by spinning the shaft of a large DC motor. Normally, the armature should turn easily, with only the friction of the bearings and the brushes to resist the rotation. However, if you short the motor leads together, the motor shaft will suddenly become very difficult to turn—perhaps even impossible to rotate by hand, if the motor is large. This braking effect is Lenz's law in action. It would also seem to have a braking effect on our search for free energy, for if Lenz's law is always true, then an "over-unity" generator is impossible.

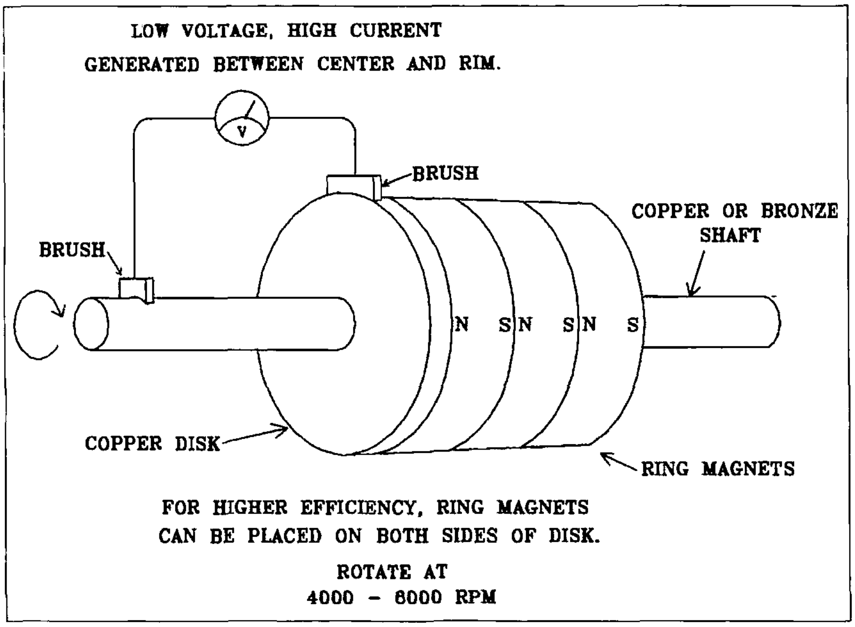

Fig. 3. Michael Faraday's unipolar generator (the "N" machine). Faraday discovered that rotating a disk in an axial magnetic field generates voltage between the center and the rim.

Fortunately, there do seem to be some loopholes in Lenz's law. While it is true that any current must create a magnetic field, and Lenz's law does predict the polarity of that field, there are a few nonconventional types of generators which do not seem to reflect this force back to the driver.

One such device is the Adams Pulsed DC motor, invented by Robert Adams, former chairman of the Institute of Electrical and Electronics Engineers, Inc. This motor uses a series of short, precisely timed pulses to energize each field magnet in succession. The field pulls a permanently magnetized armature nearly into position, then the field current is switched off. The collapsing field creates an opposite magnetic field which pushes the armature, which is by now past "dead center." As the counter field collapses, it is met by the next armature pole and another DC pulse, which starts the cycle over again. Mr. Adams has not only bypassed Lenz's law, but has in fact harnessed it!

Amateur radio operators should be able to recognize that this motor is operating in a state of resonance, and the same "flywheel" effect that we commonly see in a tuned circuit is at work here, increasing the efficiency. In radio terminology, this device is operating in class "C," as opposed to a normal motor which operates in class "A." Mr. Adams claims efficiency of over 300% in some models.

Another interesting device is Paul Brown's variable reluctance alternator, shown in **Fig. 2**. Resembling two transformer cores crossed at right angles, both magnetic circuits are opened and closed in turn by a rotating iron segment. The magnetic path for the counter field is open a good deal of the time, so efficiency is high. Some models, in fact, have shown efficiencies over 125%. Since it converts DC to AC while also acting as a step-up transformer, it should be ideal for generating 120 volts AC from 12 volts DC.

The Jameson and Kromrey motors seem to utilize a combination of the pulsed DC and flux switching techniques. It is interesting that the Takahashi scooter, which Wayne Green

described in his February 1996 "NSD" editorial, is powered by an electric motor very similar to the one invented by Raymond Kromrey in 1968. The Kromrey motor (U.S. Patent #3,374,376) uses electromagnets in the armature, while the new design by Teruo Kawai (U.S. Patent #5,436,518) uses the Takahashi super magnets for greater efficiency. The Kawai patent states that "No force opposing movement of a rotor or movable element is generated." In other words, it bypasses Lenz's law.

Fig. 3 shows another free energy device which, due to the claims made by physicist Bruce DePalma, has become the focus of discussion and controversy: the "N" machine. This generator is nothing new, since it was discovered 165 years ago. It is unique, however, since in all that time no one has yet been able to explain how it works! It is also very simple to construct—the perfect starting point for the free energy experimenter.

Faraday's "N" machine

In 1831, Michael Faraday discovered that a conducting disk rotated in an axial magnetic field produces a voltage between the center and the rim. This was surprising, since in every other method of generating electricity the magnetic field changes across a conductor, but in this case the disk is spinning in a totally homogeneous field. No change of either polarity or intensity occurs anywhere on the disk, and yet the voltage appears.

"Resisting change is like trying to put toothpaste back in the tube."

Faraday experimented with this phenomenon, and discovered another puzzle: Rotating the disk and magnet together produced the same result as rotating the disk in front of a stationary magnet. Rotating the magnet alone, however, produced no voltage in a stationary disk. From this experiment, Faraday concluded that when a magnet is rotated on its polar axis, the magnetic field does not rotate with it! He ultimately decided that a magnetic field was a property of space, somehow invoked by the magnet.

You can prove this odd fact to yourself with two small disk or ring magnets and the "peel-off" paper backing from a stick-on label. Place a magnet on each side of the paper so that they are stuck together. Now move the bottom magnet around—the top one will follow, sliding easily on the slippery surface. Now *rotate* the bottom magnet. The top one will just sit there. It will not even try to rotate with the bottom magnet. You will feel absolutely no magnetic drag to oppose the rotation of the bottom magnet, either—that's very important! It means that Faraday's unipolar generator exploits a "Lenzian Loophole." Even though Lenz's law requires that the counter field oppose the magnetic field that we used to generate the current, the fact that these fields are coaxial means that they cannot work against each other.

This phenomenon was observed by physicist Bruce DePalma in his experiments with the unipolar generator he calls the "N" machine. Spinning at 6,000 RPM, this device produced 1.05 volts at an astounding 7,200 amps, yet the power needed to drive the generator increased by only 268 watts.

Unfortunately, the unipolar generator is not yet the answer to our free energy dreams. While it does seem to bypass Lenz's law, in every other respect it is very inefficient. The electromagnet in DePalma's "N" machine consumed over 3 kW, while spinning the armature against the drag of 30 square inches of brushes required another 5 kW. The low voltage and extremely high current output from a disk rotating at high speed makes extracting the power nearly impossible, since normal carbon brushes create far too much friction, and have an internal voltage drop nearly equal to the output of the generator! A few researchers have had success with liquid brushes using mercury or even molten solder, but this is obviously dangerous and impractical.

A much better configuration was patented by Nikola Tesla in 1889 (U.S. Patent No. 406,968). Tesla's unipolar generator, shown in **Fig. 4**, consists of two disks rotating side by side, each operating in its own magnetic field. The disks are constructed with wide flanges and coupled together with a metallic belt. Reversing the magnetic field of one disk allows the two to operate in series, with the current extracted from the end of each shaft. In his experiments with this generator, Tesla noticed that when generating current, the counter

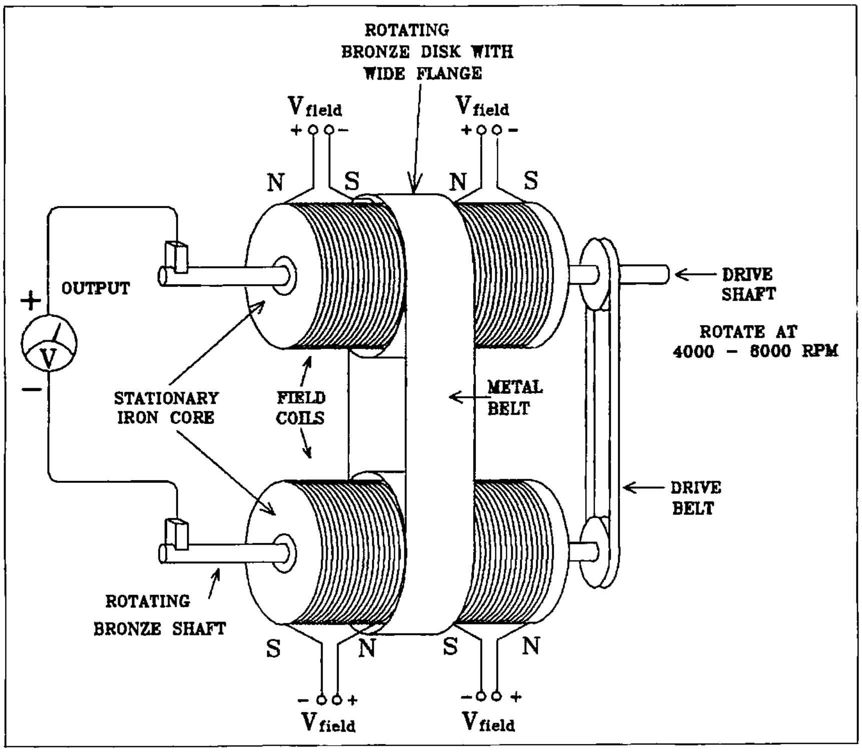

Fig. 4. Nikola Tesla's unipolar generator. Tesla made many improvements on the unipolar generator, although even he did not fully understand it.

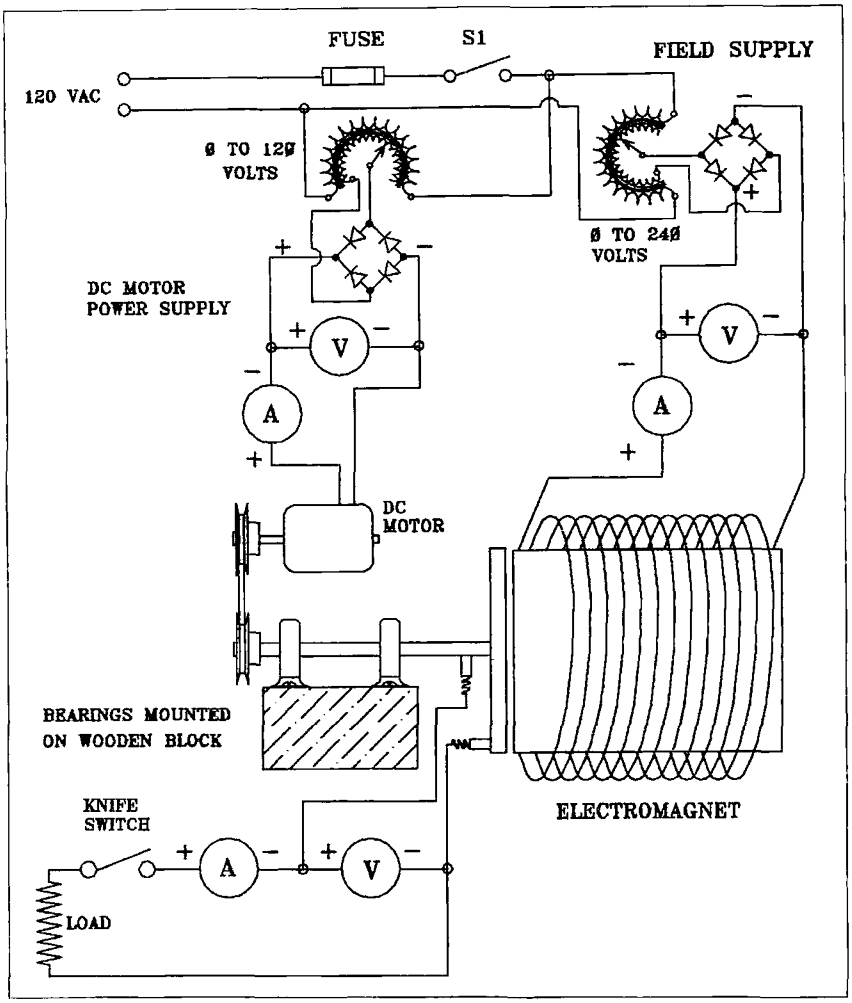

Fig. 5. "N" machine test circuit. Adjustable voltages for the DC drive motor and the electromagnet make it easier to experiment with the "N" machine.

field produced would actually *increase* the strength of the field electromagnets, to the point of eventual saturation! He proposed that, properly configured, this device could become totally self-exciting, similar to the "current accumulator" proposed by Sir William Thompson in 1865. Tesla also felt that if the solid disks were replaced with spirally-wound armatures, higher voltages could be generated—an exciting thought, since higher voltage would offset the brush losses and make the generator much more practical.

This is an area that can easily be tackled by amateurs. Experimenting with the voltage generated by different disk configurations does not require high current output, so surplus permanent magnets will work fine. Carbon brushes robbed from an old DC motor will suffice to contact the hub and rim. Disks can be cut from printed circuit board material and the various patterns etched into the copper. Does a single spiral work best, or will a double or triple pattern provide higher efficiency, much like a bifilar, trifilar-wound toroid? How about a disk cut into radial segments, like a pie? If we also split the magnet, immersing each half of the disk in an opposite field, we might be able to produce AC from this device. (Hint: Use a double-sided copper-clad disk, with half the pie-shaped elements on one side and half on the other.)

Even if the unipolar generator never becomes a practical free energy machine, there is at least one reason why amateurs should build and experiment with it: In over 160 years, no adequate theory has been proposed to explain it! Even Tesla, the man who harnessed Niagara Falls, could not understand the operation of the unipolar generator. He stated that "... the operation will be clear to us only when we shall have recognized the very nature of the forces concerned, and fathomed the mystery of the invisible connecting mechanism."

Recently, researcher Thomas Valone devised a mathematical model which explains the unipolar generator using zero-point energy fluctuations and the Special Theory of Relativity. If this turns out to be correct, for the first time amateur scientists can study a relativistic phenomenon.

Building a small unipolar generator is not really difficult, although having some mechanical skill is a plus. Steel bar stock, pulleys, belts, and pillow-block bearings are available at any hardware or farm supply store. You may even find a large solid aluminum pulley that will make a suitable disk. If you have access to a lathe, you can easily turn a disk out of brass, copper, or aluminum. The disk should be slightly smaller than the diameter of the magnets. Surplus "ring" magnets are available in the 3" to 4" diameter range, so this is a good inexpensive starting point. The output voltage is proportional to the diameter and speed of the disk, and also to the intensity of the magnetic field, so large, strong magnets are the key.

If you choose to make an electromagnet, the core can be ordinary steel bar stock, but the diameter must be at least as large as the armature disk. A coil of 2,000 turns of #22 enameled wire wound on a 4" diameter steel bar 5" to 6" long makes a good field magnet. It should draw several amps at 100 to 150 volts DC and will produce a strong magnetic field. It's a good idea to wind the coil bifilar, two wires in parallel, so that you can connect the two windings in series or parallel to match the available voltage. Be sure to cover the core with several layers of insulating tape, and also insulate between each layer of wire.

A surplus variable transformer, two meters and a bridge rectifier will make a simple adjustable field supply. You can increase the voltage slowly and watch for the point where the current sharply rises. This is the core saturation point, and you should stay well below that voltage.

An electromagnet can be made from solid stock and the disk rotated in front of it, or the core can be bored for bearings and the rotating shaft run through it. In either case, the electromagnet should

be stationary. At high RPMs a large diameter rotating electromagnet would probably explode due to centrifugal force.

Safety is always a big concern when rotating anything at very high RPMs since the centrifugal force at the rim is enormous. Be sure to mount a guard around the device to catch anything that might come loose, and remember to stay in front of the device, out of the plane of the armature. *Never* stand beside a high-speed rotating disk, guarded or not, and always wear eye protection!

A standard AC induction motor can be used to spin the unipolar generator at a fixed speed, but AC motors have a drawback: It is very difficult to measure the input power without some way to measure slip and power factor. The use of a DC motor will greatly simplify power calculations. A variable transformer and bridge rectifier, similar to the field supply, can be used to vary the motor speed while making it easy to monitor the input voltage and current. **Fig. 5** shows a typical test setup.

"He who controls magnetism controls the universe!"
Dick Tracy

Although many will argue that these free energy devices will never be practical, new technology has the disturbing habit of making the impossible suddenly commonplace. Breakthroughs in magnets and superconductors will certainly have a huge effect on power generation. But will that mean low-cost electricity from your local utility? Don't bet on it.

We need to remember that "practical" is a relative term. To some, practical means waiting fifty million years for dead dinosaurs to turn to hydrocarbon goo, then spending billions of dollars to pump it

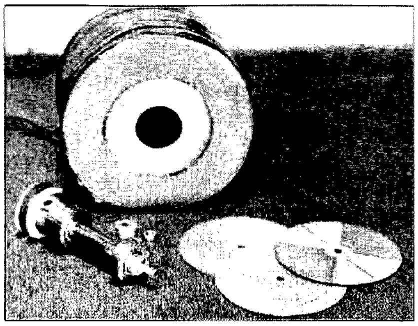

Photo B. Building the "N" machine. The shaft rotates on ball bearings that fit inside the electromagnet core. A solid aluminum disk and several experimental etched copper-clad disks are shown.

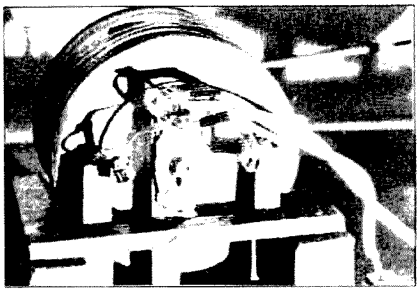

Photo C. Rotating at 8,000 RPM, the "N" machine generated two-tenths of a volt. When the output was shorted, the voltage dropped to near zero due to brush resistance. The jumper, a short piece of braid from RG-8U coax, quickly became too hot to hold.

out and refine it, finally burning it at something like 20% efficiency—poisoning the planet at every step of the process! This is obviously the most impractical system ever devised, but we are locked into it, thanks to the immense wealth and power of those who control it.

When an experimenter can build a simple device that defies explanation, it is just possible that the universe is trying to teach us something! Anomalies like this usually lead to a deeper understanding of the forces of nature, and could even launch an entirely new technology. Change can be resisted, but not for long ... that soon becomes akin to putting toothpaste back in the tube. Those who can anticipate and adapt to change will prosper. Those who cannot will eventually find themselves as extinct as the dinosaurs they now pump from the ground. 73

Quantum Theory for Amateurs

Few things are more difficult to visualize than invisible waves propagating through an intangible energy field. It is still harder to imagine that the interaction of these invisible waves makes up virtually everything in our material universe. But, since this principle will be the basis for future technology, it's well worth our time to explore it.

If we apply a source of vibrations to a point on the side of a large pan of water, we will see the energy carried away as a series of waves moving across the surface. These waves will travel until they strike the other side of the pan, then they will reflect and radiate in a new direction. Before long, the entire surface of the water will be covered with waves of the same frequency, but moving in all directions.

Whenever these waves cross one another they combine, increasing in amplitude if the waves are in phase and decreasing if they are out of phase. Since the frequency and speed of each wave is equal, the interaction between them can form a stable interference pattern. A particular point on the surface of the water will be higher or lower than the surrounding surface, and will remain that way even though the waves that contribute to it continue to move across the water. All hams are familiar with this phenomenon, since it happens when RF energy is reflected back down a feedline to interact with the energy traveling to the antenna. It's called a *standing wave.*

Just as waves move across the surface of water, waves of energy travel through the quantum field, radiating and interacting to form standing waves. The difference is that there is not one, but *four* separate fields. Energy waves from three fields combine to form *three-dimensional* standing waves. The wave pattern from each of the three fields reinforces the other two and forms a stable particle of matter, just as a triangle is the most stable geometric shape. The fourth, or gauge field, is required to keep the pattern stable as it is rotated through any axis. This ability to rotate without changing the pattern is called "symmetry," and is very important to quantum theory.

Since the particle is a standing wave, it stays in one spot while the traveling waves that contribute to it pass through. Some theorists have suggested that this causes the particle to curl in on itself, creating a vortex. This vortex action, called "spin," is responsible for magnetism, and possibly other basic forces of nature as well. Wayne Green has suggested that this spin causes a gyroscopic force that we perceive as inertia, a theory which makes sense. Inertia is not radiated by waves, and does not seem to involve the exchange of a particle, therefore it must be related to spin. There simply isn't anything else.

Multiplexed realities?

If we accept that everything in our material universe is composed of three-dimensional standing waves, then we have to accept that there is a fundamental frequency, and everything in our reality has to be composed of waves of that frequency or its harmonics. Energy of a non-harmonic frequency could also combine to create standing waves, but they would not appear to us as matter. In fact, they might not appear to us at all—a standing wave from that perspective would appear to us as a traveling wave. There could well be an infinite set of material realities occupying the same space at the same time, but out of sync with one another, each operating on a different fundamental frequency.

Now, if there are other realities overlapping our own, and if intelligent life also exists there, then they most certainly have evolved scientists, engineers, and of course, amateur radio operators. Your homework assignment is to figure out a way to *communicate with them!*

Adventures on the Red Sea

DXing in style, in an unforgettable setting.

Carol Barsky KA9SOF
4439 Hillcrest Oaks
Owensboro KY 42303

Renting a modern houseboat equipped with amateur and marine mobile equipment offers DX excitement, a variety of experiences, and new friendships.

Beautiful beaches, crystal blue water, sunny days, and starry nights—sounds like a dream vacation in Hawaii, Tahiti, or a Caribbean island, right? There is another location about halfway around the world that offers all of the above as well as a terrific DX opportunity while living in comfort—Eilat, Israel.

Eilat, a sparkling gem of a city on the Red Sea, is situated in a unique location. To the east and west, one can see Jordan, Egypt, and Saudi Arabia, their reddish-brown mountain ranges providing stark contrast to the glittering Red Sea, which stretches to the south. It is truly a paradise for those who love to be near the water as well as to explore the vast expanse of desert that rims the city. Coral reefs attract many beautiful fish and strange sea creatures, enticing snorkelers and scuba divers. Timna Park (about 20 miles north of Eilat) provides an opportunity to hike among fascinating rock formations and archeological discoveries. Also, with proper visas, you can cross the Egyptian and Jordanian borders for further adventures.

Deluxe DX accommodations

For hams, the best way to enjoy the beauty of Eilat and the Red Sea is to rent a houseboat from Meir Globerman 4X4JP. His houseboats provide luxury accommodations at a reasonable price. Each air-conditioned boat sleeps four guests; there is one bedroom that sleeps two, and the living room contains a folding double-bed sofa for two additional guests. The kitchen is fitted with a sink, refrigerator, and stove, and the dining area seats four. A color TV and radio/cassette stereo system provides entertainment when taking a break from the ham bands (if you can tear yourself away)! The bathroom contains a toilet, sink, and shower with hot water. Two small covered decks and a sun deck allow skin cancer enhancement or conversation in the fresh air. The centerpiece for hams is the marine mobile ham station mounted at the boat's helm. The radio and vertical antenna provide excellent HF coverage for hours of pileups! My husband Rich WA1GZY and I enjoyed this houseboat/ham radio vacation while visiting in Eilat last year.

Photo A. A chat with the King. From left: Meir 4X4JP and His Majesty King Hussein of Jordan JY1. (Photo courtesy of 4X4JP.)

After boarding the boat one hot May afternoon, we pulled out of the marina. The boat's engine provided a comfortable, steady cruising speed for the catamaran-style hull and we watched Eilat become a modern skyline in the distance. Off to the east, we could see Aqaba, Jordan—Eilat's neighbor—and the beautiful mountains to the east and west that reach south to the horizon. We eventually found a spot to anchor the boat and turned on the radio. Since Israel is seven hours ahead of US amateurs on the East Coast, and since good band conditions prevailed, 20 meters provided a lot of fun. European and Middle Eastern amateurs also enjoyed QSOs with us, and one evening Rich worked stations until 3 a.m.! One of his most memorable moments was attempting to talk to a Lebanese ham. He tried to establish a contact through a DX net, but the Lebanese ham stated that a QSO was not permitted—"not even for a moment." We then remembered that our status as

Photo B. Carol KA9SOF and Rich Barsky WA1GZY near the Israeli/Egyptian border.

an Israeli station changed the expected response.

Night life can be fun ashore too. The marina is near the Laguna Hotel, and a strip of interesting shops and restaurants line the marina. Tourists flock to the area in the evening for food, friendship, and musical entertainment, and many of the other fine hotels are within easy walking distance. One evening we sat by the pool of a five-star hotel after dinner just to talk and enjoy the night sky, and we stayed until the lights were turned off at 1 a.m. All of these experiences, however, make Eilat's houseboat vacations unique and memorable—and one of the best opportunities for exciting amateur radio contacts!

"The centerpiece for hams is the marine mobile ham station mounted at the boat's helm."

A continuing saga

A few months after our return to the US, Globerman called to tell us about being informed by a friend that His Majesty King Hussein of Jordan (JY1) would be making a schedule with several hams, and Globerman was invited to join in the QSO. Not only did Globerman have the pleasure of talking to the King, but the next day, while on the Red Sea in one of his houseboats, Globerman once again met the King on the air and confirmed that he was marine mobile near the Israeli-Jordanian border between Eilat and Aqaba. Since the King was in Aqaba, Globerman received an invitation for coffee and a short visit at the Aqaba palace. Globerman jumped at the opportunity. After overcoming the red tape such an unexpected visit generates, his boat was escorted by Jordanian and Israeli maritime police, and he arrived safely to enjoy a pleasant chat with the King—certainly the highlight of Globerman's amateur radio career! Globerman's experience was even featured on Israeli television and radio and in newspapers.

The Eilat/houseboat vacation and friendship with Globerman continued to affect our lives. Soon after Globerman's visit with King Hussein, Rich was listening to 20 meters when he heard a Jordanian callsign. It wasn't the King, but Rich found that he was talking to the

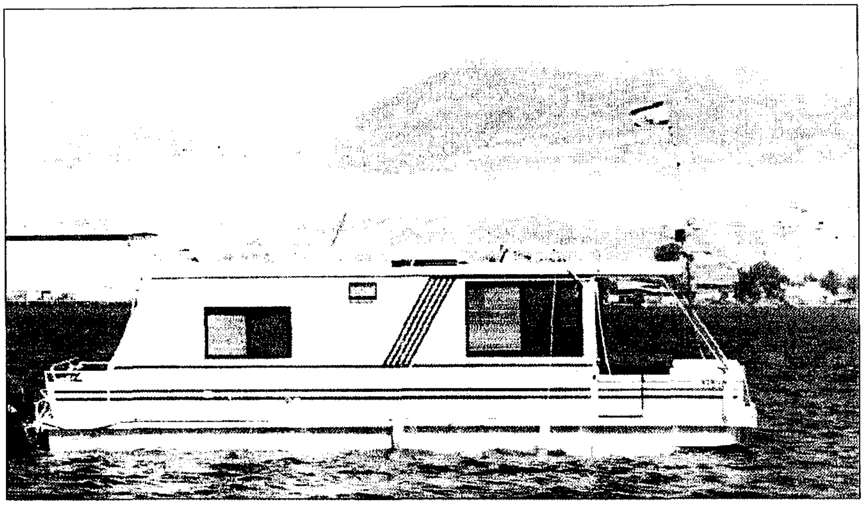

Photo C. One of 4X4JP's houseboats. (Photo courtesy of 4X4JP.)

King's pilot, JY3AK, who was flying to Washington, DC. The microphone was eventually turned over to His Majesty, and Rich made his first contact with JY1. Rich, like Globerman, basked in the accomplishment of a much-sought-after and always-treasured contact. He mentioned our vacation in the Eilat and Aqaba area, along with our acquaintance with Globerman and knowledge of Globerman's visit in Aqaba. The King said he hoped we could visit Jordan and possibly meet with him. (Unfortunately, I was outside walking our dog during this QSO and heard about it later! No, I didn't shoot the dog.)

Rich and I treasured the houseboat vacation in Eilat as a wonderful opportunity to relax and enjoy amateur radio in a different part of the world.

"A houseboat vacation in Eilat is a wonderful opportunity to relax and enjoy amateur radio in a different part of the world."

An Israeli vacation

We recommend a group tour for the other parts of Israel—especially if this is your first trip to the region. Tour guides are helpful, knowledgeable, and safety-conscious, and they provide a wonderful blend of history, religion, culture, and politics while keeping groups happy and comfortable in air-conditioned tour buses. They provide hotel accommodations in various price ranges, and breakfast is often included.

We joined a group of approximately 30 people at the beginning of our trip, saving the houseboat DXpedition for the last few days of our vacation. We enjoyed many beautiful and moving sites such as the Western Wall, Dome of the Rock, and Mount of Olives in Jerusalem, Bethlehem, Masada and the Dead Sea, Sea of Galilee, Nazareth, and many archeological sites where Roman ruins are being uncovered and reconstructed. We spent one evening at a barbed-wire-protected kibbutz in the Golan Heights, and the next morning we took a tour to learn about the residents' unique lifestyle. We stayed overnight in the beautiful port city of Haifa and enjoyed the shopping, beaches, and museums of Tel Aviv and the night life in Old Jaffa. The country offers modern shops, supermarkets, and malls, but the prices are higher than for comparable items in the US.

We're looking forward to a second trip to Israel and Jordan, and I know that one thing we will do again is venture out on the Red Sea in a blue-and-white houseboat with a small Israeli flag snapping from its HF vertical flagpole!

(At the time of this writing, houseboat rentals are $150.00 per day Sunday through Thursday. Friday and Saturday are $200.00 per day, or $1050.00 for a full week. Gas is not included. For further information, contact Globerman at P.O. Box 666, Eilat, Israel; telephone 972-7-374285; fax 972-7-373531. Operating permits are included with the accommodations.)

[Wayne's note: I don't know about the problems of taking the houseboat into Jordanian waters, but getting a ham license in Jordan is easy. I'm JY8AA. Maybe someone can overcome the bureaucrats in Egypt and Saudi Arabia and make it simple to get licenses for all four nearby countries. But at any rate, don't miss a visit in Aqaba, king or no king in residence, and then a visit to not-too-distant Petra, the lost city carved out of stone ... Wayne.] 73

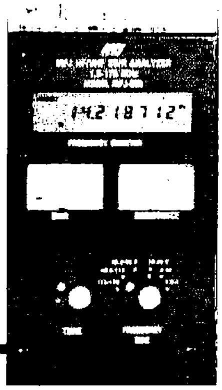
Your Next Buy: The MFJ-259

Wait 'til you see what this antenna analyzer can do for you!



Jim Pickett K5LAD
9828 N. 151st East Ave.
Owasso OK 74055-4852

We've always been told to tune a transmitter into a dummy load, and that's a wonderful idea, but what happens when we also use an antenna matchbox or tuner? That allows us to connect our transceiver to an antenna which is not a 50 ohm load, often not even close to it. The tuner can be tuned "in the neighborhood" by peaking the noise level while listening to the receiver. The transmitter, however, must still be placed on the air to fine-tune for the lowest SWR. While this latter operation is performed, the rig is connected to a working antenna and your signal will probably be making someone somewhere cuss you out. What you need is a way to adjust your antenna tuner to a perfect 50 ohm match while keeping your signal from radiating.

MFJ has just what you need—their MFJ-259 antenna analyzer, and it covers the range from 1.8 to 170 MHz, providing a readout of both your SWR and the RF resistance, using two separate panel meters. The 259 is small enough to be used portable and can be run on internal AA batteries or from a power cube in the wall. The unit has a built-in 10-digit LCD frequency counter which provides a readout of your frequency. It has a tunable oscillator which provides a substitute signal for the transmitter. Yes, the internal oscillator, when used as an SWR analyzer, will put out a signal which can be heard by a nearby station, but it is magnitudes less than when you tune up using your station transmitter. The detector circuitry of the analyzer is sensitive enough to detect the milliwatt signal of the oscillator while the station SWR bridge expects to see from 1 to 100 watts to make it read correctly. This low power oscillator assures you'll have a non-interfering signal while you are matching your antenna.

"MFJ has just what you need—their MFJ-259 antenna analyzer."

Does it work? Absolutely! **Fig. 1** shows how I hooked up my station. The antenna switch is simply a two-position antenna switch. Several companies, including MFJ, Daiwa, and B&W, make these coaxial switches.

Actually, I replaced the switch with an old coaxial relay so I can change from Tune to Operate with the flip of a small toggle switch. You may have to shop some flea markets to find a coax relay.

To tune my rig I flip the switch (S1), turn on the antenna analyzer, and set the oscillator to the frequency I want the antenna tuned to. I tune the antenna tuner to the minimum SWR on the analyzer meter and ignore the SWR meter in the tuner, since the signal from the analyzer is so very low that these meters do not even move. I also have a manual antenna switch (S2) which switches my transceiver output to a Heath Cantenna oil-filled 50 ohm dummy load. When the transmitter is matched to 50 ohms (thanks to the dummy load) and the antenna coupler input is matched to 50 ohms (thanks to the MFJ antenna analyzer), all I need to do is set the switches so the transmitter output connects to the tuner and I know I am sending maximum output to my antenna. I haven't placed my 100 watts on the air to get tuned up yet.

By the way, just to check and see if tuning the transceiver/SWR bridge/antenna coupler combination can be improved by tuning the conventional way, I tried it. I found I was tuned up perfectly.

The MFJ Antenna Analyzer is one of most useful ham tools I've ever owned. I've used it on all my antennas, including my mobile station. With my 259 I have found resonant points where I never expected to find them. For instance, I found that the Hustler antenna, with almost any resonator, also resonates at 6 meters with the resonator becoming a trap and resonating only the vertical shaft. That's pretty handy for some of those new HF mobiles which include 6 meters.

In addition, the oscillator in the 259 is very useful as a signal generator. You say the band sounds dead? When I wonder if my receiver has stopped working on a band, the 259 provides a quick answer. The frequency counter in the 259 is also often helpful.

Remember, the unit covers up to 170 MHz, so you can check all those 2 meter antennas. It is great to have an instrument to use in setting element lengths and matching networks for antennas you're building or have picked up at a hamfest.

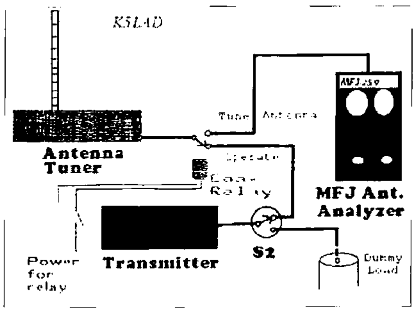


Fig. 1. Note that you can't feed the rig into the analyzer, frying it.

The Wonderful Twin-T

It's a code oscillator, a transistor tester, or even a piano. Start building!

Herbert Foster AD4UA
3020 Pennsylvania Street
Melbourne FL 32904

This little treasure has so many uses that you'll be building a bunch of 'em. It's an audio oscillator that uses no inductors of any kind. The only reactive parts are three capacitors. Add a few resistors, one of which is adjustable, and almost any transistor you have in your junk box, and you have the Twin-T circuit. It's super reliable, simple to build, and the few parts are cheap. It lends itself to just about any style of construction. It puts out a nice clean sine wave and is stable as the Rock of Gibraltar. For stability, it's almost as good as a crystal-controlled circuit, and a heck of a lot cheaper. Experimenters can have a grand old time with the Twin-T. So why hasn't it been more widely written up and talked about? I've often wondered.

It's a form of phase shift oscillator. Any oscillator is nothing much except an amplifier with its tail in its mouth. If you feed back some of the output to the input, in enough amplitude to make up for any circuit losses, and in phase with the input, it will oscillate. There's another phase-shifting circuit I've played around with that also uses a few capacitors and resistors, but the attenuation in the network is so high that the amplifier needs plenty of gain in order to get the needed amount of feedback. The Twin-T, with less loss in the circuit, does this with ease. With any given set of values in the parts of the two T circuits, at some frequency the phase from output to input will be shifted by exactly 180° and at this frequency, oscillation will take place.

The output can be taken through a capacitor of any reasonable size, .01 to .05 µF being the usual. You can connect an earphone here and get a good signal, and you can also feed this point into an amplifier circuit.

For the resistive leg of the T, use two resistors of the same size. You can start with about 39k, and a .01 µF capacitor in the T branch of that leg. For the capacitive leg, use a couple of .01 µF capacitors, but make the resistor in the T branch adjustable. Radio Shack™ sells a multi-turn pot that adjusts with a screwdriver and gives a very wide range. Buy a RS Catalog No. 271-343. It's a 10k pot with a screw adjustment that takes 15 turns to get from one extreme to the other. Any transistor that I've tried in this circuit has worked. You just need to see to the correct polarity of the power supply. In experiments I've run, 6 to 9 volts will do the job.

"Any transistor I've tried has worked in this circuit."

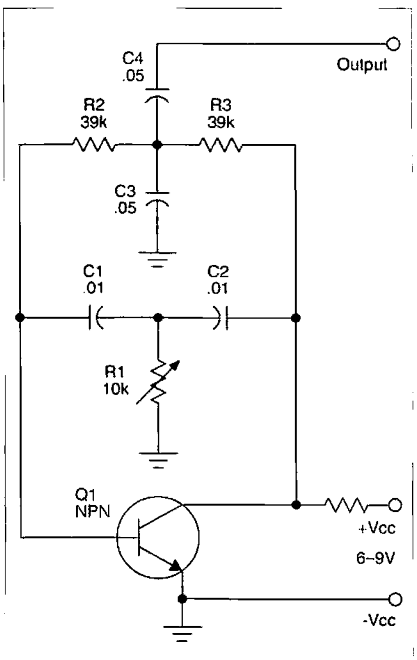

Fig. 1. Basic circuit for the Twin-T.

Although I'm showing the circuit values I've used, be sure to play around with your own values and see what you can do. You might even invent something! If you've been looking for a simple circuit with which to try your hand at making a PC board, you can't go wrong with this one.

Uses for the Twin-T

After you have your Twin-T running, and have marveled at its simplicity, it's time to consider the many uses to which the Twin-T can be put. Perhaps the first one that comes to mind is a code practice oscillator. You can build one into a very small container and fit a straight key into the hot lead of the battery. Add an earphone, and you're home free. If you'd rather have a speaker going, go back to Radio Shack and buy an Amplified Speaker System, Catalog No. 32-2031A. It runs off of four C cells or a 9-volt wall transformer.

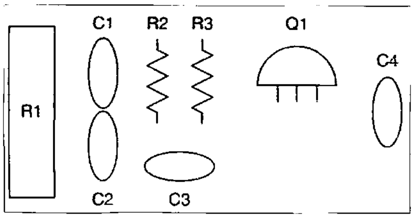

Fig. 2. Suggested parts placement on a 1" x 3" perf board. Use hook-up wire to connect the points. Place R1 so that the screw is accessible.

If you build your Twin-T on a small piece of perf board or as a printed circuit, you'll find that a small piece about 1" x 3" will take the entire circuit. This board can now be installed into the Speaker System mentioned above by simply placing it inside the enclosure. You'll find buckets of room where the small board can be placed. There's no real need to fasten it down. It will easily stand on the wires leading to the battery. Trace the positive lead from the battery holder to the ON-OFF switch, which is located on the amplifier board. Carefully tack-solder a wire to the load side of the switch, and run it through a straight key to the positive voltage input on your Twin-T board. Run a wire from the negative battery holder to the negative input on your board, or just connect that point to the amplifier's ground point; that's all it takes. If you now turn the system on, hold the key down, and advance the volume control, you should hear the Twin-T putting out a nice clean signal. You can then adjust the multi-turn pot until the frequency is satisfactory. If you are unable to reach the pitch you want, try different sizes of resistors in the T branch containing the two resistors. Just remember to use two resistors of the same size.

For another use of what you've just made, remove the straight key and replace it with a momentary contact push-button switch. Install this in the top of the amplifier case. It's a good idea to include a pilot light. Use an LED in any color you like for this. You now have a very good oscillator for use in zero beating a CW station. Set the pitch to equal the offset frequency of your transmitter. I have such a gadget right beside my transceiver and use it any time I'm up in a CW mode. I've also made copies of this and presented them to friends. They invariably like it. You will too, if you try one.

If you build this version of the Twin-T, be sure to add a pilot light in the top of the amplifier case. Without one, it's easy to forget that the zero-beater is on, and walk away to do something else while your batteries run down. The push-button switch, of course, goes in series with the battery lead to the Twin-T board. This version takes an NPN transistor.

The Twin-T will start every time, all the time, with never a miss or hang-up. This makes it ideal for a musical instrument. With such an inexpensive circuit, you can easily make a discrete circuit for each note. About two and a half octaves will make a keyboard that any kid will have a ball with. If you are also into woodworking, you won't have much trouble fabricating a piano-like keyboard. A fast trip to your local library and an inquiry into electronic musical instruments will give you the frequencies needed for your project. Or just visit any well-stocked music store and buy a circular pitch pipe. You can easily adjust the various notes in one octave by checking the aural beat note between your oscillator and the pitch pipe.

A few words about an aural beat note and how to use it might be in order here. With the oscillator working, and connected to a speaker, blow into your pitch pipe. You should hear both notes. If they are reasonably close in frequency you'll hear a rapid flutter superimposed on them. As you adjust the screw on the multi-turn pot, the frequency of the Twin-T will change, and the flutter will become faster or slower, depending on the direction of the adjustment. If your adjustment is in the correct direction, the flutter will become slower. As you get closer to the correct setting, the flutter will start to sound more like WOW-wow-WOW-wow, as the two notes join in phase to produce a maximum, or oppose each other for a minimum. If you can make the WOW-wow slow down to about once per second, you're within a hertz of the right note. Keep trying, and you'll find that you can make the wow stop almost entirely. You can beat up and down your keyboard, using the harmonics, to set other octaves.

This will sound odd, but don't try to get precisely on the frequency. If you try for high order precision and achieve it, your instrument will sound lifeless. A true pipe organ, which is the standard against which any instrument is judged, varies slightly in pitch as the pipes and tone modifiers change with humidity and temperature. Electronic organ manufacturers have gone to some amazing lengths in attempts to duplicate this slight dissonance.

Getting back to uses in the ham radio field, consider two of these Twin-T oscillators used as the required tones in checking an SSB transmitter. The big caution here is that the two tones should not be harmonically related. This subject receives a lot of attention in the *ARRL Handbook*.

Because of the reliability factor of the Twin-T, consider using it as a transistor checker. Use three short leads extending from the proper points in the circuit, terminating in small alligator clips. Each lead should be of a different color, no longer than about six inches, and marked for connection to the collector, base, and emitter of a transistor you'd like to test. You'll also need a double-pole double-throw switch to reverse the battery polarity so as to accommodate either an NPN or a PNP transistor. This can not only check the item for operation, but also determine which type it is. If a given transistor oscillates, it's good. Such a tester can even check many transistors in-circuit, as long as the circuit components are not of such a value as to swamp all oscillations. I have such a device in my tool box and consider it to be of great value. If my tester says a transistor is bad, I take it out of the circuit and test it again, before I give it the heave-ho into the trash barrel. But if the tester says it's good, I look elsewhere for the trouble.

You can let your imagination run wild here in playing with this wonderful circuit. Nothing will explode, and you aren't going to disrupt the environment. Furthermore, you don't have to own the keys to Fort Knox to finance your project. Have fun!

A Kite/Balloon-Supported Zepp for 160 Meters

Make your antenna fly high!

Stan Gibilisco W1GV
2301 Collins Ave. #A 632
Miami Beach FL 33139

Here's a way to really put out a big signal on 160 meters! Hook your antenna to a balloon for some really spectacular results. I've made a number of changes to improve the efficiency of this antenna since my article "Balloon-Supported Antennas for HF" in the September 1988 issue of *73 Amateur Radio Today*.

Efficiency without radials

Many people say that a good ground system is necessary for antennas to perform efficiently. This is not true with certain types of antennas. An end-fed antenna does require a low-resistance ground if its input (feed) impedance is low. However, when an end-fed wire antenna measures any integral multiple of a half wavelength, the input impedance is extremely high and a low-resistance ground is not nearly as important. Since a low-loss ground generally requires many radials, an antenna is much simpler, cheaper, and easier to install if its feed-point impedance is very high.

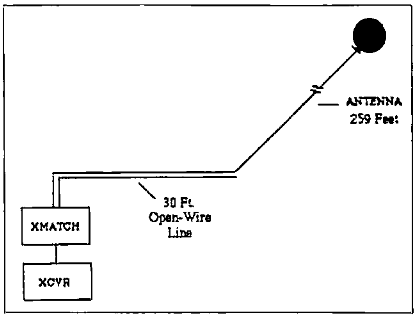

Fig. 1. Basic scheme for the balloon-supported half-wave zepp. The feedline may actually be any length; it was used primarily to get a good match with a transmatch that could not handle the half-wave antenna alone.

I chose a length of 259 feet (78.9 meters) for my end-fed wire antenna. This represents a half wavelength at 1.810 MHz. For a 160 meter contest, I planned to operate mostly between 1.800 and 1.820 MHz with the FT-101EE. Above 1.820 MHz, power must be reduced with this transceiver to keep spurious emissions under control, and 85 watts output is little enough power on this band.

I laid down two radials and employed a water-pipe (cold) ground at the station to provide a fair ground system. Using an antenna with a feed-point impedance on the order of several thousand ohms, the ground loss would be low even if the ground resistance were as much as 100 ohms—and that is a pessimistic estimate for the ground system I used.

Zepp-feed advantages

Unfortunately, my transmatch could not match the extreme impedance of the half-wavelength, end-fed wire antenna to 50 ohms for the FT-101EE. It seems the unit did not have enough inductance to accomplish this, but the transmatch did provide a 1:1 SWR if the antenna were zepp-fed with 30 feet of open-wire transmission line (**Fig. 1**). This may seem strange—that, by introducing reactance into the feed-point impedance, a match could be easier to get than with zero reactance—but apparently the transmatch could tune out reactance enough to allow the somewhat lowered resistive component to be matched to 50 ohms. It worked, and that was all that mattered to me.

With zepp feed, the bandwidth is very narrow and the tuning of the transmatch extremely sharp. I was careful to ensure that the antenna was exactly 259 feet (78.9 meters) long. I measured it with a tape measure bought just for that occasion! If the operating frequency is much different from the exact resonant frequency of the antenna, the feedline will become unbalanced and will radiate. This occurs a little bit even at resonance, but is not significant over the range of 1.800-1.820 MHz.

Zepp feed has several advantages. It can be used not only with a half-wave radiator, but also with a radiator that measures any integral multiple of a half wavelength. Also, it allows you to locate the antenna feed point away from the station. However, the SWR on the parallel-wire feeder is quite high so it is important to use a low-loss open line. Television "twinlead" is generally not good enough.

Balloons for calm or light winds

The main difference between my earlier station and the current station is the position of the antenna. In 1987 it was about 25 feet (8 meters) above the ground; now it consists of a sloping radiator with the near end at ground level and the far end about 180 feet (55 meters) above ground. The wind results in a slope of about 45 degrees with the supports described here.

The balloons I used were either 40 inches (1 meter) or 54 inches (about 1.4 meters) in diameter at maximum inflation. I got them, along with the helium gas, from a local welding supply store. I used rubber stoppers to seal the balloons after inflation. A small screw eye in the stopper provided for the connection of the antenna, using a kite swivel (**Fig. 2**).

The antenna wire is Baygard 6 electric fence wire, which is lightweight and quite strong. The conductors are aluminum so the wire has excellent conductivity and low loss. I backed up this wire with nylon twine in case the wire came loose. You don't want to have the balloon fly away with all or part of the conducting line dangling from it!

For increased stability in light-to-moderate winds, glue a disk to the stopper (**Figs. 3** and **4**). This tends to deflect air downward. I have used disks of about three feet (one meter) in circumference with success to prevent the balloon from "heeling over" and becoming nearly useless in winds of 10-20 miles per hour.

Another stabilizing method is to use a kite in conjunction with the balloon. A dime-store variety eddy bow kite works well for this purpose. The kite is flown with the balloon behind it (**Fig. 5**). It is important to attach the kite securely to the balloon. You may need a heavier bridle on the kite than if it were flown alone. Also, the kite and antenna must be light enough for the balloon to lift them when the wind dies down.

The antenna spool and safety precautions

The antenna wire and tether cord may be wound on an electric cord spool, available in most hardware stores. This spool allows rapid retrieval of the antenna and easy extension. It also provides a way of anchoring the antenna. I use a belt with extra holes punched in it to fasten the spool to a tree or other anchoring post (**Fig. 6**). A small insulator is attached at the end of the antenna to reduce end effects. The feedline is connected with a clip lead, as shown. It is important to fasten the whole assembly securely at all splice points.

There are several safety considerations that must be observed when an antenna of this type is used:

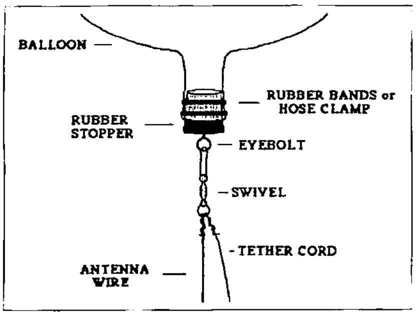

Fig. 2. Base attachment for connecting the balloon to the antenna wire and tether cord.

- The antenna must be shorter than the straight-line distance to the nearest above-ground utility line. The reason for this is obvious if you value your life!

- An atmospheric charge may develop on the wire, even in clear weather, so be careful because you can get a severe shock from the antenna wire when it is fully extended and not connected to the transmatch. A grounded wire may be used to discharge any potential before touching the wire.

- This type of antenna should never be flown during severe weather conditions or near thundershowers.

- It is best not to fly this type of antenna where it may come down on a roadway or other congested area.

- Federal Aviation Administration regulations require that a kite or balloon not present a danger to people, property or other aircraft. Further, balloons greater than 6 feet (about 1.9 meters) in diameter, or kites that weigh more than 5 pounds (2.27 kilograms), require special FAA permission before being used. (These large devices are not normally needed for amateur antennas.)

Larger kites for moderate winds

In winds gusting to more than about 20 miles per hour, balloons do not behave well, so it's better to use a kite. A good choice for this purpose is the winged box kite, or delta-Conyne. These kites are available by mail from Into the Wind, 1408 Pearl Street, Boulder, CO 80302. Other types of kites that work well are the plain delta and the airfoil or Parafoil design.

Some larger kites, especially the delta-Conyne and airfoil, will pull hard, with up to 150 pounds of tension. A strong tether line is a necessity for these kites. Also, larger kites will have sufficient pull to require more sophisticated reel-in devices than the simple cord spool. Generally, a parafoil should be eight square feet or less, and a delta-Conyne should have a wingspan of eight feet or less. This is all that is required for a half-wave or even a full-wave 160 meter antenna.

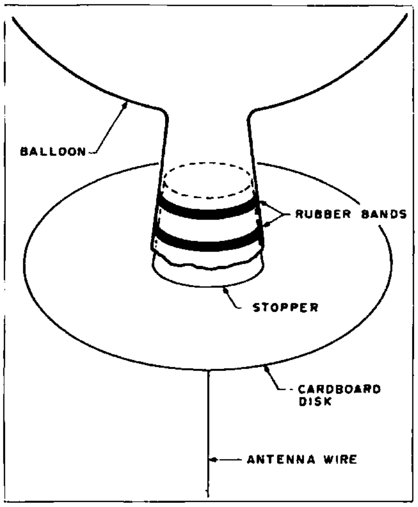

Fig. 3. Addition of a stabilizing disk for better balloon behavior in light-to-moderate winds.

For the future

The antenna at W1GV during a 160 meter contest in 1988 was what I call a "balloon sloper." On the first night of the contest, December 3, the wind was from the southwest. Therefore, the optimum direction for the sloper was toward the southwest, and the worst direction was northeast. On the second night the wind was from the north-northwest, shifting to west. The optimum direction for propagation was therefore north-northwest, and shifted to west later on.

For a domestic contest, such as a 160 meter contest, moderate-to-high angles of radiation are actually more desirable than low angles. From the Minnesota location, a north wind is less desirable than a south wind if a balloon or kite is used to support the antenna.

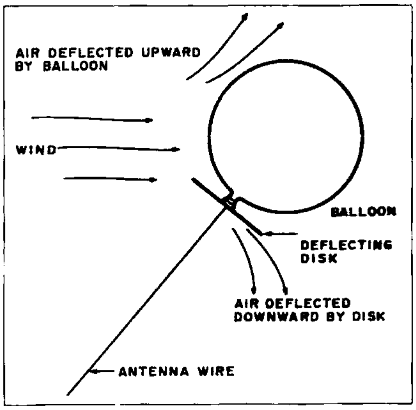

Fig. 4. The cardboard disk serves to stabilize the balloon in winds. The upward force from the disk balances the downward vector caused by air flowing around the balloon itself.

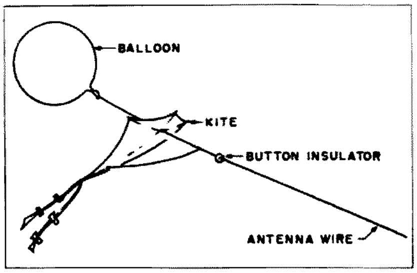

Fig. 5. Addition of a stabilizing kite for improved operation in moderate winds.

In the future, I might use another option for this method of antenna support. A full-wave wire will be held in a vertical position by guys made from 20-pound-test fishing line. This will result in a maximum radiation angle of about 36 degrees with respect to the horizon. The same feed system will be used. The antenna is shown in **Fig. 7A**, and the radiation pattern in **Fig. 7B**.

Other possibilities include flying a second wire near the driven wire to get a parasitic array. The second wire could be lengthened or shortened to render it a director or reflector. This scheme would require that the wind be out of the north or south, ideally, so that the maximum radiation would be toward the east or west.

Of course, Mother Nature has something to say. High winds, thundershowers, ice storms, snow, or heavy rain make it difficult or impossible to fly this type of antenna.

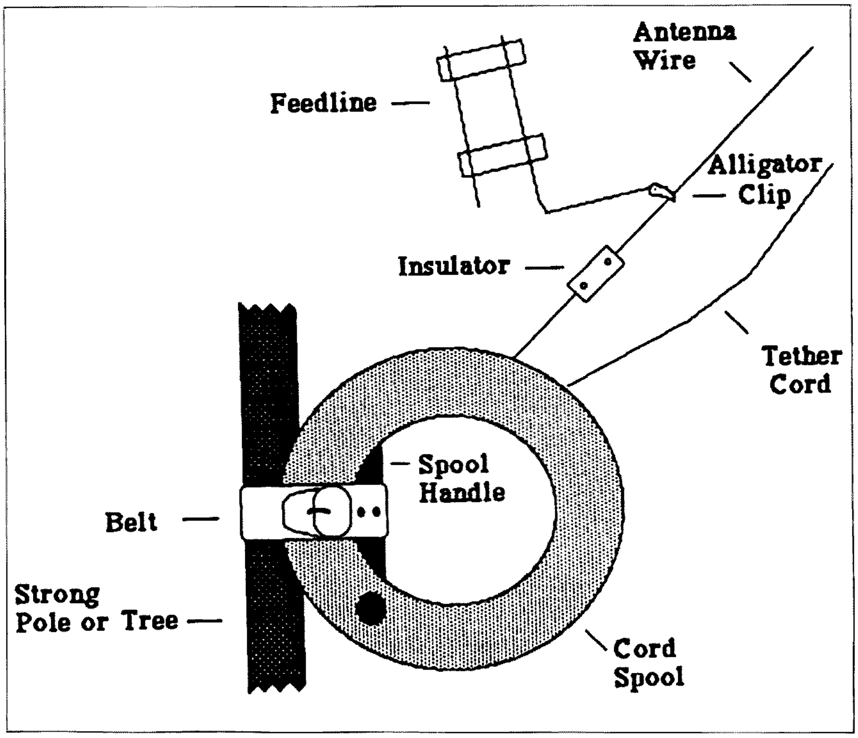

Fig. 6. The cord spool is anchored to a pole or tree using a belt with extra holes to allow it to be strapped tightly. An insulator reduces the end capacitance of the antenna. The feedline is connected with an alligator clip.

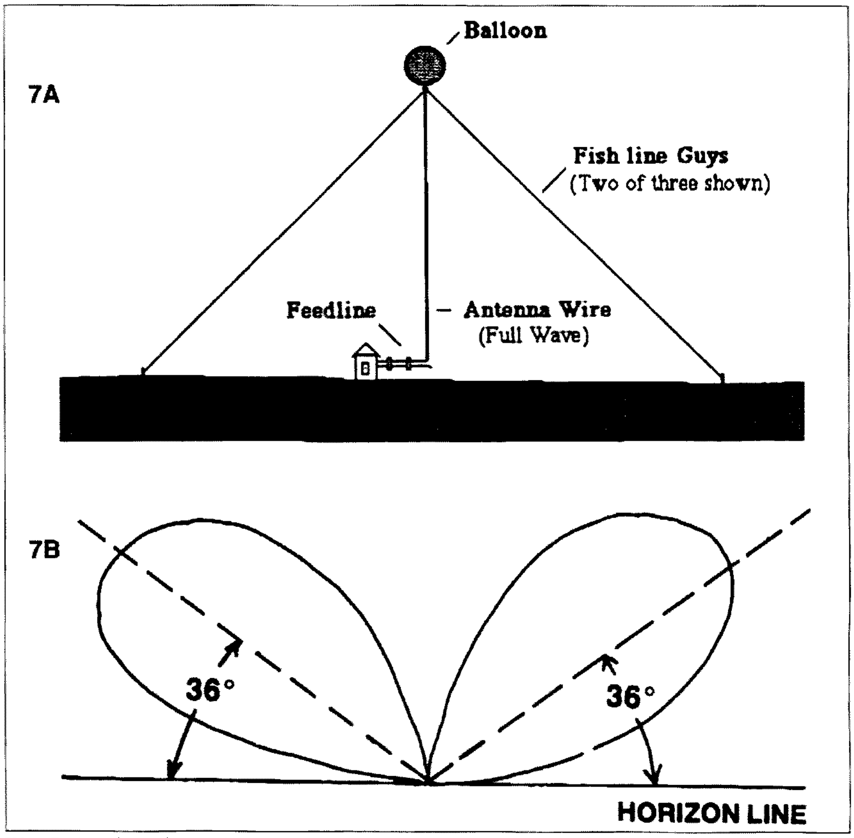

Fig. 7. A) The scheme for a vertical full-wave antenna. The height would be 530 feet for 1.810 MHz. B) The expected vertical-plane radiation pattern. The antenna would be omnidirectional in the horizontal plane and would theoretically provide excellent stateside performance from a central location such as Minnesota.

My Indoor Antenna Farm

Yes, you really can work DX with a stealth antenna.

Robert W. Vreeland W6YBT
45 Maywood Dr.
San Francisco CA 94127

Radio operators of the French Resistance often used indoor antennas with satisfactory results. A typical Type B Mark II suitcase radio had a 6L6G final with an output of about 20 watts. The recommended antenna installation zigzagged wire across the ceiling to form a top capacitance. Another zigzag on the floor served as a ground counterpoise. The vertical portion that did most of the radiation was only about eight feet long.

Indoor antennas have several advantages. First, they are out of sight (my years on the TVI Committee taught me that the ham with the highest tower got the most complaints.) Second, the antennas are protected from the weather, so they can be built without elaborate waterproofing or windload requirements. And third, no dangerous roof or tower climbing is required.

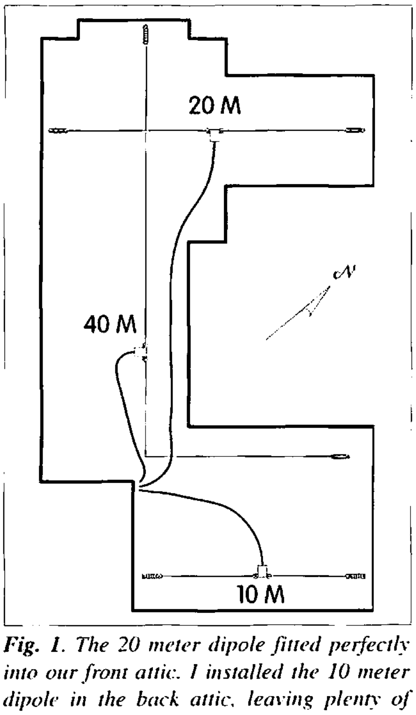

Fig. 1. The 20 meter dipole fitted perfectly into our front attic. I installed the 10 meter dipole in the back attic, leaving plenty of room for a 75 meter loop and a dipole for 15 and 40 meters.

"Tar paper, shingles, and a half inch of plywood are all that stand between my 20 meter dipole and Japan."

I prefer to have a separate antenna and tuner for each band. The antennas can then be pretuned and simply switched for band changing. My QTH is an English Tudor style house on the western slope of a hill. It has a peaked roof with a 17 in 12 slope. Only tar paper, shingles, and a half inch of plywood stand between my 20 meter dipole and Japan. The front of the house is 35 feet wide, just right for a 20 meter dipole (**Fig. 1**). In order to reduce transmission line loss, I have placed my 10 meter dipole in the back attic, right above the operating position. The dipole I use for 40 and 15 meters runs from the front of the house to the rear, then makes a 90-degree bend into the attic, where the walls are filled with insulation backed with aluminum foil. The foil-backed insulation is also laid over the ceiling, thereby insulating the attic from the living area. Of course, the unbonded aluminum foil is not a good electrical shield, so it has minimal effect on the antenna system.

What about 75 meters? A 120-foot dipole just wouldn't fit. A quarter-wave dipole fed by a quarter-wave resonant open wire line was a possibility. This was an attractive choice because the line would actually be part of the antenna, thereby permitting tuning over a fairly wide range. However, I didn't want to bring the open wire line down to the operating position. I then considered a half-wave voltage-fed loop. As in the case of a half-wave dipole, the ends of the loop would be very high voltage points. This called for the use of a quarter-wave open wire feedline. You will recall that a quarter-wave line with a short or a very low resistance at one end will have a very high impedance at the other end. In order to avoid bringing the open wire line into the shack, I used 70 ohm transmitting type twin lead for the last 11 feet. This twin lead is no longer manufactured but you could use RG-8/U instead, if you are not too fussy about maintaining a perfectly balanced line. Actually, I added 15 feet of RG-8/U between the antenna switch where the 70 ohm line terminates and my Yaesu FC-757AT antenna tuner. The VSWR at the tuner output is 3.5 at 3775, 1.7 at 3880, and 3.1 at 4000 kHz.

Number 14 insulated house wires, spaced at four and a quarter inches, were used for the open wire line. It is 45.5 feet long. The spacers were cut from one-inch PVC water pipe. The loop itself is a single run of number 14 house wire extending with numerous bends all the way from the front of the house to the back attic and back. Its total length is 146 feet. This length was determined by the reliable cut-and-try method. Due to the presence of metal gutters and chicken wire lath, all of the antennas

Cheap and easy fixes for TVI.

Terry Staudt WØWUZ
616 N. Sheridan Ave.
Loveland CO 80537

Though I wasn't the father of the coaxial ground, a claim to being the first cousin is in order. I honestly felt, through personal experience and feedback from many other hams, that it was the end of TVI. That was until a neighbor acquired a projection TV and antenna designed for use on Wyoming ranches in the back of beyond.

My transmitter is clean, and I always check my stuff and ask around to see if anyone has a problem. If and when they do, it's usually evident when I'm standing there talking to them—so that lets me off the hook.

It would seem that my neighbor with the projection TV had a problem. Bear with me, as it's a little difficult. Channel 2 in Denver shows rather good movies with commercials that approach the threshold of pain, but know how to stop just in time.

TVI had gone from the old days, when wiping out the channel was cause for concern, to the present, when a 10% reduction in color is enough to cause the neighbors to storm your lawn with pitchforks and flaming torches. This calls for the best effort from all of us, considering the alternative.

Hey, I've got the same problem, I hear you cry. Here's the reason and some cheap positive steps to fix it.

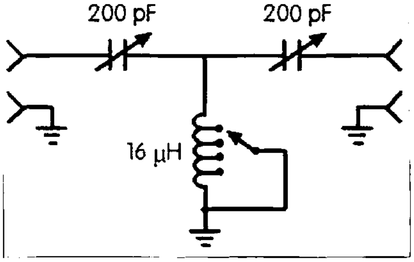

Fig. 1. The T-match.

The pi-network

Like a lot of you, I use a T-match antenna tuner—a little MFJ-943 that works just fine and is identical to almost every unit on the market. The fault with the T-match is that while it's able to load a coat hanger, there is almost no harmonic attenuation, which I need to protect my neighbor with the sensitive TV. I use a modified G5RV, a 102-foot dipole fed with 300-ohm twinlead. Really, all you need with a resonant antenna is a line flattener. Using a T-match is overkill when a pi-network will do. In addition, the pi-match gives up to 30 dB of harmonic attenuation and tunes very smoothly. Best of all, it's easy to turn your T-match tuner into a pi-match device.

Fig. 1 shows the schematic of the T-match, listing some common values for the coil and caps. **Fig. 2** shows a pi-network that takes about 45 minutes to accomplish with your existing T-match tuner—the only parts needed are a couple of plastic parts drawer dividers to place under the inductor after it's lifted from ground. The capacitors "float" in a T-match, so all you have to do is reconnect the input wire to the output wire and ground the other terminal to an existing chassis point on each.

The lifted ground on the inductor goes to the output lug on the second capacitor. In most cases, the ground wire, if you're using a tapped inductor with a rotary switch, is the one to be rerouted to the output capacitor. **Fig. 3** shows the whole modification, which is easily reversible should your circumstances change. You've just spent 45 minutes, and reduced your potential harmonic output by 30 dB.

Harmonic attenuation

OK. You're using a T-match, and the antenna is a squirrel. What to do? There's an old chestnut that calls for a capacitor of about 5-12 pF to go from the center of the "T" to ground for harmonic attenuation. The problem is that this high "Q," consisting of the capacitor and leads, is resonant *somewhere*—usually not in the area of interest, and about as sharp as a knife as far as bandwidth is concerned.

A check with my Heath solid-state dipper while transmitting on 10, holding it against the twin-lead coming out of the tuner, did indeed show a little something at 57 MHz. A few milliwatts, to be sure, but that's all it takes! The TV signal is far down from this in a fringe area!

What I did was to make a simple series trap out of junkbox parts; that cured the situation completely. A broadband trap lets me absorb the harmonic completely, and is tunable over a small range. There are a few pitfalls, so I'll tell you exactly how to do it and why.

The cure

Wind a coil of about five turns of #20 solid insulated wire around a roll of dimes (or something of similar diameter), close-spaced (about 0.8 µH). Coat it with DuPont Duco™ or model cement, and let it dry for several hours.

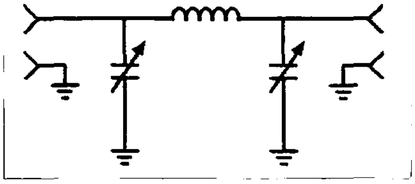

Fig. 2. Pi-match.

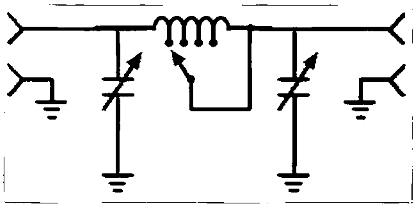

Fig. 3. "T"-to-"Pi" match.

This is a good time to scrounge the parts. You will need a compression mica, a glass piston or small air variable capacitor with a value of about 5-25 pF, a 0.001 µF disc capacitor at 1 kV or higher if running more than 100 watts, and two 100 ohm, 2 watt resistors. These are assembled as shown in **Fig. 4**, with the two resistors in parallel, to make a 50 ohm load to absorb the harmonic. Just shunting the little devil to ground won't cut it, as all you've done is attach it to the chassis of the tuner to radiate in fine style.

The procedure is quite logical. While transmitting on 10 meters, using a dummy load if possible, hold the dipper coil near the trap coil and adjust the capacitor to null the harmonic out. It isn't terribly critical as the Q isn't sky high—on purpose. It's sacrificed for a bit broader bandwidth. This may be done with someone watching Channel 2 if you don't have access to a dipper. In my case, after I had done this, I put the dipper coil into the tuner inductor and checked from 50-250 MHz to see if there were any more snakes in the grass. If there were, they were hibernating.

Proper grounding

What the heck is a coaxial ground? It's simply a method of shielding your ground cable, so any signal radiated off the ground wire is shunted back to ground. Despite having been printed in four publications at least six times, many hams have never heard of it. These hams are also the same fellows who have monster RFI problems, while the local "experts" drink all their beer and tell them it's one of nature's unfathomable mysteries. The first thing these poor souls tell me is that they are *positive* every item in their shack is grounded! I don't doubt that a bit.

If manufacturers really wanted to save a little money, the ground connection on accessories would be a great place to start! What that little double-nutted screw on the back of an audio filter, or that #2 copper battery braid, does is set up ground loops that let your RF have the time of its life!

The *only* thing you ground is the *RF generator*—meaning the transmitter or receiver—*not* the linear, tuner, rotor box, preamp, low-pass filter, keyer, phone patch, EXT, VFO, AUX, or the dog. To use the water analogy for RF: *Keep it in the pipe (coax) and let the coax shield do the grounding automatically!* This is so obvious that no one does it.

To make a coaxial or "zero length" ground, you just need two 0.001 µF 1kV disc capacitors and enough RG-8X to reach from your rig to the ground rod, which should be at least six feet, driven next to the foundation where moisture is retained. Using a stainless steel worm-driven auto fuel hose clamp, attach the bypassed center conductor of the coax to the rod. Waterproof it with glue, caulk, or acrylic spray. It doesn't matter if you're on the third floor; the ground length is still very short—just a matter of inches. The other end goes to the RF generator. That's the only ground connection you use (see **Fig. 5**). Use any or all of these methods in combination, and you'll definitely be off Channel 2 for good!

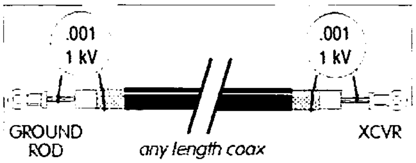

Fig. 5. The coaxial ground.

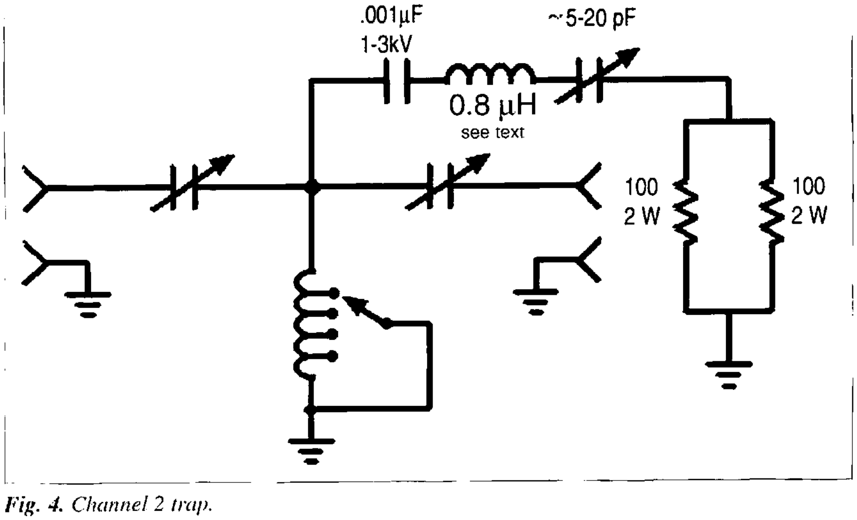

Fig. 4. Channel 2 trap.

My Indoor Antenna Farm

Continued from page 29

required pruning. The metal in the structure also detuned the 40 meter dipole, making it difficult to find the electrical center of the antenna. TVI has not been a problem. The small amount of interference introduced by the 20 meter antenna over the family room was quickly cured with a high-pass filter on the TV set itself. The only place where I haven't been able to cure the interference was with the burglar alarm. The sound of sideband audio emanating from the speaker is annoying, but hasn't damaged the unit or affected its operation.

Of course, the indoor loop is not as effective as a full-sized outdoor dipole. It is, however, just fine for working southern Oregon from San Francisco. My friends in Japan and Australia may be interested to know that this was the 20 meter indoor dipole I used to work them with my 20 watt MOSFET amplifier (References 1-2). It just goes to show that a resourceful ham, like the members of the French Resistance, can still make important contacts while keeping a very low profile!

TD-3 Subaudible Tone Decoder Module

Hamtronics' kit saves one club's treasury—and provides a group project!

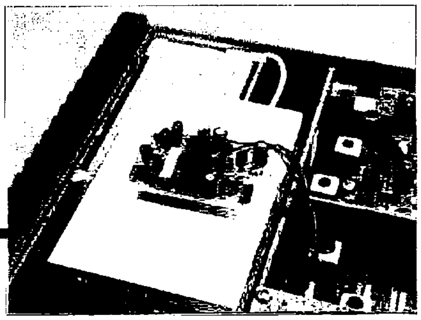

Photo A. The assembled TD-3 Encoder/Decoder ready for final installation in the repeater chassis.

Larry R. Antonuk WB9RRT
P.O. Box 452
Marlborough NH 03455

Our ham club's simple repeater system had been in service for almost five years. It was just a basic controller, with a CW ID, hooking together a couple of converted commercial mobile rigs. The duplexer was whipped up by a couple of the guys in their machine shop. We had pooled our money and come up with enough to buy a real antenna and had talked the cable TV guy into letting us have some space on his tower. Overall, it was a good machine—it rarely needed service, and covered all of the area we were interested in.

The trouble started one winter. We noticed the thing keying up by itself every once in a while. Mostly noise, but now and then you could almost make out a voice. We checked the repeater from one end to the other—everything was right up to spec. The noise got worse until it got to the point where several of the locals were no longer monitoring the repeater frequency—it was just too irritating. Even the RACES guys turned their scanners off at night. Eventually, we were able to make out a callsign or two—from another state. It wasn't just squelch noise we were hearing. The repeater was being keyed up by very weak signals from another distant repeater system.

But wait a minute! These guys were operating on *our* frequency! We were coordinated! As it turned out, *they* were coordinated, too. It was only when some of the mobiles were transmitting from the peaks of high hills that they were just strong enough to key up our machine.

"But wait a minute! These guys were operating on *our frequency!*"

Finding a solution

Once we knew what the problem was, the solution was simple. At the next monthly club meeting, a proposal was put forth. In order to keep our machine usable, we had to eliminate the noise problem. Obviously, the best way to do that was to add a subaudible CTCSS (continuous tone coded subaudible squelch) tone decoder to the repeater. This tone, commonly referred to as PL (private line), would be used to gain access to the system. All the users would have to do was to dial this tone into their synthesized rigs, and they'd be all set. A show of hands, and the proposal was soundly defeated.

Wait a minute! Another show of hands, and the reason became obvious. Only about 10 percent of the active users had rigs that had PL capability. Most of the group had older synthesized rigs, and some still had crystal rigs. No one was willing to shell out the bucks to add a PL encoder to his radio, since they weren't really going to get any immediate benefits from it. The proposal was shelved until the next meeting.

Over the next week or two the problem was kicked around, and a new idea came up. What if those other guys already had PL on their system? We could just set up our repeater to *not* repeat when it heard their PL. Since our signals were always stronger, it wouldn't matter if they were on the air when we were transmitting. Our non-PL signal would just override their weaker PL signal, and the repeater would kick in. It seemed like a good idea, and after a few phone calls it turned out that it would work. The other repeater definitely used CTCSS decoding. All we needed was a PL decoder for the repeater.

Hamtronics to the rescue!

At the next coffee shop meeting of the Technical Advisory Board we looked over the specifications on the various CTCSS decoders. We had several requirements—quality, dependability, ease of use, and customer support. Since the club had an abundance of technical ability and a shortage of funds, we considered building the unit ourselves, but the most cost-effective solution turned out to be the TD-3 Subaudible Tone Decoder/Encoder Module from Hamtronics. The TD-3 was available as a low-priced kit, which made the treasurer happy. It was based on the time-tested NE567 IC, using a straightforward circuit, so there were no custom chips to worry about if it ever needed troubleshooting. It had a built-in encoder, so when the day came that we had to switch over to genuine "PL" operation we'd only have to move a couple of wires. Best of all, the TD-3 was backed by the folks at Hamtronics—we were all familiar with their history of customer support. We gave the information to the treasurer, and he put a check in the mail to Hamtronics.

A week or two later the UPS truck dropped off the TD-3. That Saturday we met at the shop to build and install the unit. We opened the box and found just what we expected from Hamtronics: a high-quality glass-epoxy circuit board, high-quality parts, easy-to-follow instructions, and plenty of set-up and troubleshooting tips.

The board was finished in about 45 minutes, even with the "help" of three kibitzers. Testing and checkout were simple. We had access to a frequency counter, so we simply needed to hook the counter up to a test point and adjust a pot for the right tone frequency. The TD-3 covers any frequency in the CTCSS band, from 63 to 250 Hz, in six different ranges. The proper range is set by changing the value of a resistor connected to the NE567. Once the unit is set to the right frequency the sensitivity is adjusted. This is simply a matter of adjusting a pot until a signal with a minimum amount of tone (we used 200 Hz deviation) can be detected. Normal CTCSS systems like to see anywhere from 300 to 600 Hz of deviation. Adjusting for slightly less than the minimum value lets you accommodate radios that may be a little out of alignment, without being so sensitive that the unit falses on voice audio.

"The board was finished in about 45 minutes, even with the 'help' of three kibitzers."

The results

Once the TD-3 was assembled and tested, we went to the hill. The TD-3 was designed for use with the Hamtronics line of repeater controllers. It normally inhibits the COR signal from the repeater receiver, preventing repeater PTT until the TD-3 hears the proper tone. In our case, we needed just the opposite: We needed to inhibit PTT when we *did* hear the proper tone. This turned out to be a relatively simple task. The TD-3 uses an open-collector output transistor that goes low when no tone is detected, keeping the COR line low. Rather than using this on the COR line, we simply lifted the ground on the last PTT transistor before the transmitter and connected it to the open-collector output on the TD-3. The repeater operates the same as before, except that the ground for the PTT switch transistor comes from the TD-3. If the TD-3 is not detecting the proper tone the open-collector transistor is turned on, which grounds the output. This ground is fed to the PTT switch transistor, which puts the repeater into transmit. If the TD-3 is able to detect a tone, however, the open-collector transistor opens and removes the ground reference from the PTT transistor, which prevents it from keying up the repeater.

As a final check, we put the repeater on the air and ran some tests with mobiles and handhelds in our area. We found that even when the repeater was inhibited by a distant signal, a local handheld was able to overpower the weaker signal and hold the repeater on without any dropouts or flutter. The operation was a complete success!

The TD-3 has been in service for quite a while now and has survived lightning strikes, power surges—and a small family of mice that moved into the repeater cabinet. We saved a good deal of money by building it ourselves and are fully prepared for the inevitable day when we'll have to switch over to conventional CTCSS operation. Most importantly, the repeater is quiet. If we hear something, it's a legitimate user using the system. The RACES team is once again monitoring the local channel. The TD-3 Subaudible Tone Module comes highly recommended.

FRACVERT: Small Fractal Footprint Vertical

Fractal counterpoise, or top hat too!

Chip Cohen N1IR
2 Ledgewood Place
Belmont MA 02178

Ground planes and counterpoises seem to be one of those dark areas of knowledge for most hams. Here's a good rule of thumb: Only a few radials (most people use 1/4 wave) cause a radiating counterpoise (bad news); lots of radials make the vertical give off most of the RF (good news). Ultimately, an infinite ground plane is the best situation as it affords additional gain; however, for that, you can dream on.

I've been impressed by some of the weird ways that HFers have accommodated the ground counterpoise problem for HF and MF. Europeans seem particularly vexed by this problem since they usually have small lots, and all seem to want to get on 160m and work W6s. Their radials are turned sideways, in hairpins, twirls or pretzels, or whatever. They seem to take up the entire lot. I'm not sure if these are genuine solutions; you might be able to get these counterpoises to match for 50 ohms, but chances are they radiate badly (that is, very well)—and into the ground itself.

"The radiation resistance of this vertical is higher than a conventional system, hence the better SWR and bandwidth."

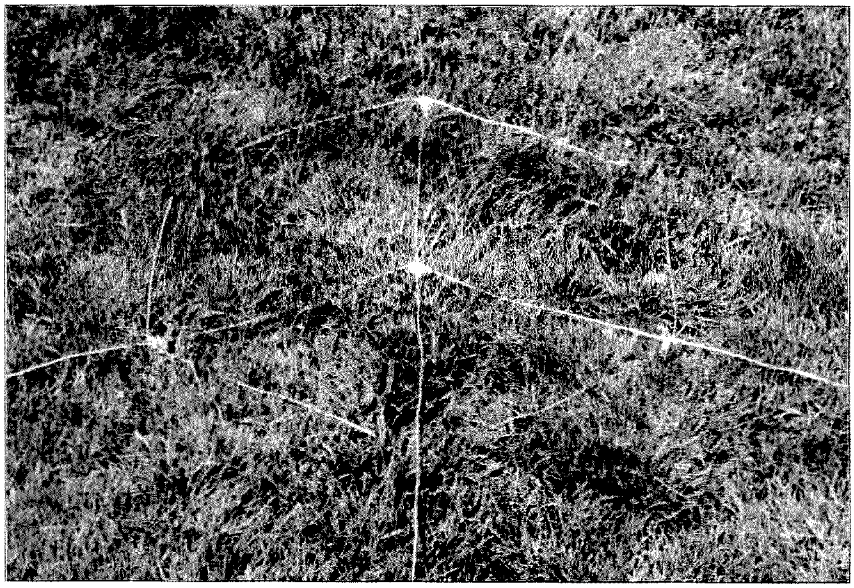

Photo A. The author's 20m version of a fractal counterpoise; like a spiderweb, it's not as fragile as it appears.

Try fractals

Fractals have provided a worthwhile answer. Here I present a radical radial counterpoise which appears to have all the benefits of a multiple (a dozen or more) 1/4-wave radial system. But it takes up less than 1/20 of the area. For those who want the NEC simulations and more technical details, these can be found elsewhere.[1] For now, here are simple details for making such a ground for HF verticals.

Technically, the fractal pattern of the radial ground counterpoise is called a "third-order ternary dendrite," as shown in **Fig. 1**. The vertical is attached at the center where the three primary "branches" meet. I made my counterpoise out of thick aluminum ground wire, then twisted and crimped the wire and covered it with aluminum tape. Many prefer to solder it (good luck soldering aluminum!). Copper wire is a good substitute, and easier to solder.

Electrically, the fractal counterpoise is equivalent to a lumped circuit of series/parallel-connected capacitors/inductors. The branching replaces the usual parallel arrangement of having many radials. In hindsight, it seems strange that branching hasn't been a well-known (if known at all) alternative in ground

counterpoises. Fractals provide a natural alternative solution to a counterpoise's equivalent circuit.

The fractal pattern is important, although a pinch of deviation will give negligible degradation. If you want to scale all the lengths properly, keep in mind that the system can be viewed as branches with branches with branches.

There are three primary branches that start from the center and form the outermost extents. Each of these is 0.088 wavelengths. Use a ruler to scale the others as needed, and at your frequency of choice.

For my 20m version, shown in **Photo A**, the longest branch (there are three of these) was 5.8 feet. Compare this to the 16.5-foot lengths of conventional spoked radials for 20m and you can see the huge real estate savings. The counterpoise was on the ground, although it should work equally well when buried, or even better when raised a few feet above ground. If you're using a ground rod without radials now, this is an easy way to beef up your ground system. Unless you live on a postage stamp, this means you can now put on radials for a 40m or 80m vertical in a small lot. All you need is the vertical itself.

Speaking of the vertical, there is a minor change. Instead of being 1/4 wave long, it needs to be lengthened to 0.3 waves. On 20m that means increasing the length by 2.5 feet. The change is easily accommodated by a coil if needed on 80m or 160m.

Performance

How does it perform? In a comparison test with a 20m vertical with four radials of 1/4 wave, it seems to have an S-unit (the mythical 6 dB S-unit) edge. This is higher than modeling would predict; it should make much less than a 1/2 S-unit difference, mostly because of the higher radiation resistance and less horizontal radiation from the fractal counterpoise. No matter; it works better, in addition to being smaller. It's comforting to know that less RF is going into the ground, heating the air, or worse. Incidentally, the bandwidth (2:1 SWR points) is a broad 700 kHz at 14.2 MHz center. Minimum VSWR is 1.3:1. The radiation resistance of this vertical is higher than a conventional system, hence the better SWR and bandwidth. The VSWR shows that the ground losses are minimal.

Some experimenting is still in order to see how well the fractal counterpoise works as a multiband system. Some quick checks show that a 30m counterpoise works on 10m, but I don't know yet if it radiates (sure don't want it to!). Experimenting is needed; new fractal territory ahead!

"You can now put on radials for a 40m or 80m vertical in a small lot."

It *is* possible to make very small counterpoises and still have good verticals—but they need to be made 1/3 wavelength in height or more. A solid circle of the fractal's radius also works well at the dimensions given here. But at much smaller radial sizes, the fractal seems to have an advantage with a higher radiation resistance and bandwidth. This present combination provides an easily-made counterpoise with excellent 50 ohm match, but if you want a really *tiny* footprint, just shrink the fractal counterpoise and increase the vertical!

Top hats

Finally, you may have noticed how verticals are getting turned upside down these days, with huge radial-like top hats capping them off. Top hats are a very old idea, and a very good one because they allow you to shorten the vertical height by about a factor of two or more. The radiation resistance drops to about 20-25 ohms (from 35 ohms), but for most of us that's not a problem; good efficiency is still attainable.

Top hats themselves don't radiate (much), and shouldn't. This is not their problem; their size is. Typically top hats run up to 1/4 wave. That's huge!

A more modest "cap" can be made using the ternary fractal. Placing the fractal at the top of the short vertical allows it to be matched. I am not a big fan of top hats, but for those who need them (160m-40m ops), the conventional top hat can be replaced with a ternary fractal cap (or other fractal). A direct comparison for several different sizes shows that for a given vertical electrical length and top hat comparison, size savings of 20%-50% are typical. Again, a bit of experimenting pays off. **Fig. 2** is a schematic of a 1/8-wave vertical with a ternary fractal top hat, next to a 1/4 wave. It provides almost equal performance. For the truly brave, there's a fractal hat and a fractal foot—but that's a subject for a later paper.

Jazz up your vertical with a ternary fractal counterpoise or top hat. Either way, the size savings will be substantial, and you'll have the most radical radial antenna around.

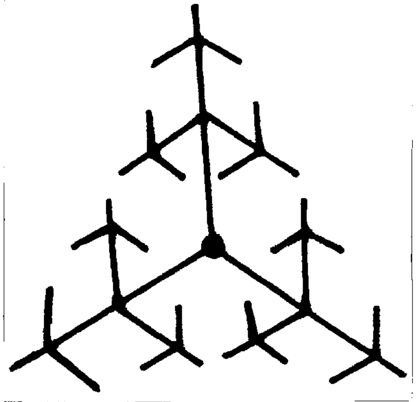

Fig. 1. *The fractal pattern of the radial ground counterpoise, called a "third-order ternary dendrite."*

Have We Been Had?

Again?

William Wells WA8HSU
The Indiana Repeater and Auxiliary Council, Inc.
Box 1092
Logansport IN 46947

I am sure that many of you have heard about what was called the "Big October Meeting." For those of you who have not, it was a meeting called by the ARRL for those of us in the frequency coordination community to discuss our problems and talk about setting up a national organization. I am Bill Wells WA8HSU, Chairman of the Indiana Repeater Council, and I attended that meeting. Why should you care about this? Well, this will have an impact on repeater coordination and band planning all over the country, so if you operate on the VHF/UHF bands or ever plan to operate on the VHF/UHF bands, you'd better care! Before I continue, a definition of "Ex Parte Communications" might be helpful to you. An Ex Parte Communication is any communication which is not part of the public record, concerning a pending or proposed legal action (a rule-making is a legal action) which may influence the outcome of the action. Example: I talk to the judge who is conducting your trial for drunk driving and tell him that I saw you drinking with my wife and you were stoned. This is an Ex Parte Communication because I am not a witness; that is, I am not called to testify at the trial. Ex Parte Communications are not only immoral, they are also illegal. I ask you to consider the following material carefully and then ask yourselves if an Ex Parte Communication was involved.

The nation's frequency coordinators were called to this meeting in St. Charles, MO, by the ARRL. We were told that the first order of business was to respond to a request from the FCC that they (the FCC) be provided with a single point of contact to interface with the coordination community. In fact, we were sent a total of seven different agendas for this meeting if you count both those which arrived by Internet E-mail and those which arrived by good old USPS snail mail. All of these agendas contained the following item as agenda item number one:

1. Discussion and Decision: Response to FCC request that it be provided a single point of contact with the coordination community, through which the FCC would recognize and support local and regional coordinators. (This was cut from an E-mail message which was sent on September 11, 1995, to the Coordinators Internet Remailer by Steve Mendelsohn WA2DHF, former ARRL Hudson division director, now the ARRL first vice president).

> ***"Book publishing is something which the ARRL does very well and they make a lot of money doing it."***

Well, this seems pretty clear-cut. We were told that the FCC had requested that the League set this thing up for them so we all went (some of us not very happily) to St. Charles MO, on October 7, 1995.

The ARRL had all their heavyweights there: President Rod Stafford, Executive Vice President Dave Sumner, General Council Chris Imlay, and half a dozen or so division directors and members of the executive council. This heavyweight presence would certainly belie the ARRL claim that they were only there to serve as meeting facilitator. Ralph Haller, the FCC deputy wireless bureau chief, was there and gave a short address to the group following a pep talk by Rod Stafford. Following his address, Mr. Haller held a question and answer session. During the Q & A session, Steve Wilson WB9SHY, the vice chairman of the Indiana Repeater Council, put the following question to Mr. Haller: "... Did the FCC, YES or NO, request the single point of contact (discussion) for the Coordinators' Meeting?" Mr. Haller's answer was, "No, we did not request it." Several minutes later Steve Wilson, now holding up a copy of the meeting agenda said, "I am holding in my hand a copy of the meeting agenda which was published by the ARRL which states: 'Discussion and Decision: Response to FCC request that it be provided a single point of contact with the coordination community.' Did the FCC, YES or NO, request a single point of contact for the coordinators?" Mr. Haller's answer again was, "No, we did not request it." Following that answer Rod Stafford quickly assisted Mr. Haller down from the speaker's platform. There is a videotape of this available to anybody who doubts me on this point.

Several times during the meeting ARRL representatives stated that they (the ARRL) are not frequency coordinators and have no interest in becoming a frequency coordinator. If you have a very recent copy of the Amateur Radio Service Rules, please turn to 97.301 (e) (3). This rule now states: "No amateur station may transmit in the 219-220 MHz segment unless the licensee has given written notification of the station's specific geographic location for such transmission in order to be incorporated into a database that has been made available to the public. The notification must be given at least 30 days prior to

making such transmission. The notification must be given to: The American Radio Relay League, 225 Main Street, Newington CT 06111-1494."

It sure sounds to me like the ARRL is in fact a frequency coordinator and has usurped coordination of 219-220 MHz from the local and regional frequency coordinators, such as the Indiana Repeater Council, which are defined in the FCC rules at 97.3 (a) (21).

When the meeting came to a close it appeared as if the ARRL had been appointed by the coordination community as the single point of contact with the FCC. The Indiana Repeater Council, seeing a secret agenda at work here, went away very dissatisfied with the outcome of the meeting. A weekly amateur radio tabloid broadcast erroneously reported that Indiana would never support the SPOC even though we had provided a written statement to its editor of the conditions under which we would support a SPOC.

I want to state for the record that the Indiana Repeater Council is satisfied with the work of the drafting committee which was appointed at the meeting and will support the new national organization which has been proposed.

As I stated, we saw a secret agenda at work so we decided to investigate. The Indiana Repeater Council filed a Freedom of Information Act request with the FCC, asking for information concerning the supposed FCC request for a SPOC. One document which we were sent was most interesting. It is a letter from the ARRL Rocky Mountain division director and Chairman of the ARRL Ad Hoc Repeater Committee to Ralph Haller.

The letter is herein quoted in full.

"Dear Mr. Haller:

I want to thank you for the most enjoyable visit Rod Stafford, Chris Imlay, and I had with you earlier this week. You were most cordial and ***we appreciated your attention and input to our*** [emphasis added] ***repeater proposals***.

To summarize our meeting Monday, June 19, 1995:

1. The ARRL will hold a meeting in St. Louis, October 7, 1995.

2. We are inviting about 100 repeater coordinators to attend. The League will sponsor and chair the meeting as facilitator primarily for the benefit of the repeater coordinators. Secondarily, we hope the FCC (you) may benefit from organization and cooperation worked out by the coordinators themselves to help you solve repeater coordination problems arising from time to time. Thirdly, ARRL is acting in the belief the meeting may benefit the League members and all amateurs through better cooperation and coordination of amateur repeaters.

3. It is our sincere hope that you personally will be able to attend.

4. We view as goals: A. Appointment of repeater coordinators—including recognition of present, non-challenged coordinators. B. Setting of qualifications and criteria for appointment of coordinators. C. Licensing of repeater stations, with coordination a prerequisite to licensing. D. ***Single point of contact*** [emphasis added], through which amateurs will contact the FCC. E. An accepted method of dispute resolution, including methods of appeal and review. Consideration of whether the FCC should have a role in such resolution, and if desired, what such role should be.

5. The League neither proposes nor urges a role for itself beyond this single meeting. The League is acting solely as a facilitator, with the hope of seeing a national cooperative coordination resulting in widespread, effective use of repeater communication.

6. We look for you (the FCC) to agree with the goals set forth above and propose such regulatory action as may be necessary [emphasis added].

7. We look for an agreement among the coordinators that will provide the sort of self-regulating activity the Amateur Radio Service has traditionally enjoyed.

If you have any suggestions for the items covered in this letter, would you please send them to me, Chris or Rod.

Once again, thank you for your hospitality, kindness, and helpfulness to us and to the League."

There you have it. This letter shows that the SPOC was an ARRL idea, not an FCC idea. You add that to Mr. Haller's clear statement at the meeting that the FCC did not request the SPOC and you can see that this was an ARRL show all the way. Now, I am not a lawyer, but bearing in mind the definition of Ex Parte Communications which was presented at the beginning of this article, it would appear that if the ARRL Chairmen as well as Stafford and Imlay have not committed Ex-Parte Communications, they are at least well down that slippery slope and they have at least carried out a great deception on the coordination community as well as on the amateur community in general.

But why, you might ask, would the ARRL want to promote this deception? What do they get out of the deal?

One thing is greater stability in the coordination community. This, everybody agrees, would be a good thing. There is something else which they would get if they were appointed as the SPOC: control of all the coordination databases, which would guarantee that they could publish any repeater directory product they wanted and be forever free from any possibility of being charged a

royalty for use of the data. This would also place them in a position to prevent any other publisher from using those same databases. It would also place them in a position to eventually charge you a fee if you wanted to coordinate a repeater and to set a national band plan.

Now, I have no objection to the ARRL publishing a repeater directory. Book publishing is something which the ARRL does very well and they make a lot of money doing it. The *ARRL Repeater Directory* is in fact the ARRL's most profitable product. By publishing a repeater directory the ARRL is in fact doing me as a frequency coordinator a great service. However, we at the IRC, and most other frequency coordination councils, operate on a shoestring budget and the council officers often put up hundreds or even thousands of their own personal dollars to get the tools needed to provide the service which we provide to the amateur community.

A fair royalty charged to any publisher, including the ARRL, for the use of the coordination databases which we generate and maintain could fund the national organization which the ARRL seems to want as well as the underlying local and regional frequency coordination councils.

So I call on the drafting committee to keep the SPOC organization completely free of the ARRL and to negotiate for the coordination community a fair royalty for the product of our collective labor. I would say that a good starting point for this negotiation would be 10% of the sales revenue plus 20% of the advertising revenue generated by the product to be licensed to be divided between the national organization and its underlying local and regional frequency coordination councils. What the ARRL and all other publishers would get for their money is better frequency coordination, more accurate databases, and greater stability in the frequency coordination community. The ARRL and other publishers would therefore be able to produce a higher quality product for you, the amateur community. 73

NEVER SAY DIE
Continued from page 9

With all due respect to this year's banquet speaker, they should have spent whatever it took to get Jean Shepherd K2ORS/4 up there on the podium. I don't know of anyone else in ham radio who can entertain like Jean. Old-timers will remember him for years on WOR every night. They'll remember his stories in *Playboy*, his books, and his movies. Pry him out of Sanibel Island.

I may be doing Paul Shuch, this year's speaker, an injustice, but since I have a lot of trouble with his whole SETI idea, considering it a big waste of time and money for reasons I'll cover in my editorials, his talk didn't make me want to go to the banquet. Shep would get me to the banquet, if I were coming to the HamVention. And he might tip the scales, if all else was equal, to bring me to Dayton.

Hey, it's show biz, guys.

SETI

Ask me why I'm sour on the search for extraterrestrial intelligence (SETI). Okay, glad you asked.

It has to do with cosmology and the age of the universe. Have you read any of the books on the subject on my recommended book list? Even if you accept the big-bang theory, which is more of a religious matter than one of scientific fact, the universe checks out to be at least 15-20 billion years old. And our earth is only a measly four billion or so.

And our poor old solar system is way out there on a remote arm of our galaxy. Thus, if you accept that life somehow is able to get started on new planets where the right conditions prevail, and considering that there are hundreds of billions of stars, presumably all or most with planets, the likelihood is that there are billions of worlds where life has developed to a fairly advanced stage. The likelihood is also that a bunch of these got started even billions of years before we did. Or even more, if you are not a worshipper of the big-bang theory.

Now let's switch to radio communications, which is a big deal right now. One hundred years ago scientists were managing short-range contacts with spark and Morse code. In a hundred years we've gone from spark to digital TV via satellites and global communications. Now, do you honestly believe that we are not going to make anything significant in the way of further communications developments in the next hundred years?

If you'd been a scientist a hundred years ago, how accurately could you have predicted the communications systems we have today, with cellular phones, paging, faxes, the Internet, and so on? Am I off-base to suggest that today's scientists have just as little chance of predicting what communications will be like in 2096 as those of a hundred years ago? And once you're with me on that, let's go to what communications systems

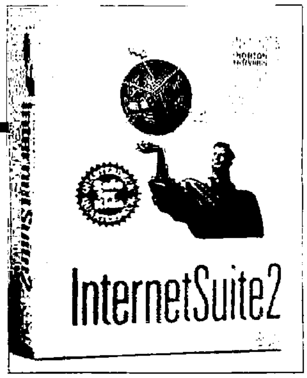
Communicating on the Internet

With Quarterdeck–license-free!



Don Johnson K7UGQ
23 David Street
Enfield CT 06082

Once the little secret of college students and computer techies, the Internet has emerged as a popular method of communicating with hundreds of thousands of people. Unlike ham radio, where the media of transmission is RF energy, Internet communication takes place over the telephone lines. The Internet offers state-of-the-art, noise-free multimedia contacts with companies, hobbyists, and organizations, etc., without requiring a code test! In fact, it requires no license, test, or demonstration of computer or telephone knowledge. A true Plug-and-Play form of communication—or is it?

"This package has everything but the kitchen sink!"

Prior to 1993, communicating via the Internet required learning obscure UNIX commands, coupled with several different executive programs for each of the different tasks performed on the net. Mail programs, telenet programs, dialers, and browsers were commonplace. In fact, you would never have used the words "multimedia," "program integration" and "Internet" in the same sentence. Talk about an oxymoron!

Like the rest of computer technology, Internet software continues to evolve rapidly. Although the improvements are transforming the way individuals communicate, the rapid pace of change is often frustrating, as is the possibility of choosing the wrong software for your needs. When software is quickly developed and brought to market, it's often difficult to use. Initially this was true with Internet software.

Several programs are necessary to complete the complement of software for full-up Internet communication. Individual ancillary Internet programs can be obtained from any number of software dealers or downloaded, often as developmental software. Some companies offer many of these programs, integrated as a suite of Internet applications. Bundled software often offers similarity of operations between applications, and/or commonality of file service. This translates to ease of set-up and operation. If you think setting the clock on your VCR is clumsy, try installing Internet software. A whole new world of terminology and technology is standard equipment when dabbling on the net. For example, the following statement was extracted from a browser's set-up sheet: " ... make sure that you obtain a service provider that offers a local telephone number PPP capable of TCP/IP connection with full HTTP capability." Throw in set-up questions like: "List your domain address, your popd and smtp address and your IP address," and now you're ready to pull the plug.

One supplier of integrated Internet software has gone an extra mile to assure success for first-time Internet computer users. The Internet Suite II program by Quarterdeck Software™ not only offers a full multimedia browser, but all the optional Internet tools required to establish an Internet account, or use an existing account, with very little effort. In fact, the box should have a label reading something like " ... prior Internet knowledge not required ..."

Quarterdeck's Internet Suite II© is an integrated set of essential (and then some) communication programs for both on-line and off-line communications. Designed for Windows 3.X and Windows 95, this package supports both Internet and INTRANET (Internal Local Area Network) communications, and is loaded with goodies. Real Audio Players, QuickTime movie viewers, Adobe Acrobat viewers, full functional Internet Directory, and Norton Utilities anti-virus software are included with the package. A very nice addition is the Cyber-Sitter, providing parental control over sexually explicit matter. Not only is this an easy program to install and operate, but it's a safe one too!

Component highlights

Qmosaic Browser: The most common piece of Internet software and surely the most talked about is the browser (see sidebar). The Qmosaic Browser supports HTML 2 conventions with data security and full encryption, and provides very fast multiple document reads. Powerful drop-and-drag support eases organizing Internet addresses.

Qmessage Center: More than just an E-mail program, the true power of integration shows up here. Full-featured Electronic mail, Usenet and Newsgroups are among some of the message center features.

QTerm (TELNET): Emulates DEC VT52, VT100, VT220 data terminals.

QFTP: Point and click interface that works with Windows File Manager to allow downloading of software from other people's computers to your own.

Global Chat: Participate in live chat sessions using Internet Relay Chat (IRC). Chat rooms are similar to having a packet QSO.

QWinsock: Contains a multi-feature dialer that can coexist with other winsock programs installed. Automatically detects and identifies your modem and executes dial-up procedures whenever an Internet application is run.

Location Manager: Provides phone numbers the user can dial to access the Internet and handles all the details. Includes the initial "Connect and Play" feature, a list of over 80 percent of the leading Internet providers, including the phone numbers and set-up strings. Additionally, over 250 popular modem phone numbers and set-up strings are included.

Each module can be modified to satisfy your individual preferences. If it weren't for the default settings, the amount of user configuration could become a real headache. For the beginner, too much versatility may be a disadvantage. However, as you progress from the Newbie stage to becoming a more proficient user, you'll appreciate the power of a fully configurable program.

The users' guide consists of over 400 pages of tips, screen drawings and instructions to assist you toward success. The guide is also organized in a logical sequence, set up the way most people would discover each module in the suite. If you can't find something in the documentation, try asking Quarterdeck via any one of the avenues given.

While including so much, Quarterdeck did leave out a few, albeit minor, features. Internet Suite cannot handle newsgroup threads, level 3 HTML, or Java support (if you aren't sure what these features are, don't worry. They handle advanced initial on-line connection to the Internet and tie together news groupings by subject). Missing from the excellent user guide is assistance for the Cyber Sitter, Anti-virus, and real audio/video components of the package. There is, however, more than adequate on-line information to assist you with these advanced programs.

As I said, this package has everything but the kitchen sink! There are other Internet programs that offer a little better capability individually, but nothing as well integrated, as much fun, or as easy to get started as Internet Suite II. After you get logged on to the Internet, send me an E-Mail. I'll send you a reply E-Mail confirming the QSO, a sort of QSL card from the state of Connecticut. Care to try for Internet WAS? Besides being another form of communication, it's a lot of fun!

Contact: Quarterdeck Corporation, 13160 Mindanao Way, Marina del Rey, CA 90292-9705; phone: (310) 309-3700, FAX: (310) 309-3217; E-mail: support@quarterdeck.com.

Web Browsers

Web browsers provide a computer window into the Internet world of graphics and information. Before today's plethora of web browsers, Internet searches were text-based, offering no real multimedia excitement for the viewer. Credit for the first real web browser goes to the National Center for Super Computing Applications. As the creators of a program called MOSAIC, they almost single-handedly opened up the World Wide Web to public viewing and scrutiny. This one development is credited with sparking the phenomenal rush to get on the Internet.

Several commercial companies saw opportunity in improving the original MOSAIC program. Each company added their own bells and whistles; however, most browsers in use today are related to the original MOSAIC program.

An Antenna Plotting Oscillator

Here's a handy one-chip piece of equipment you can build.

Richard Q. Marris G2BZQ
35 Kingswood House
Farnham Road
Slough SL2 1DA, England

My interest in experimenting with small loop antennas, mainly for 80 and 160 meters, got me interested in building a small signal source to use for checking their radiation patterns. For years I used an old surplus BC-221 frequency meter as a source, but when I read about the Harris HA7210 low power crystal oscillator, available in an eight-pin IC, I knew it was time to upgrade my test equipment.

A big old BC-221 is okay for checking small rotatable antennas, but I wanted to be able to check the radiation patterns of larger low-band antennas, and that meant being able to move the signal source around, instead of the antenna. The HA7210 is a crystal-controlled Pierce oscillator which can be programmed to operate between 10 kHz and 10 MHz. All it requires is the addition of a parallel mode crystal and a 0.1 µF bypass capacitor, plus a DC supply of up to 10 volts. The power consumption is well under 1 mA, so even a 9V transistor radio battery will do the job just fine. The circuit is shown in **Fig. 1**.

Changing the links between pins 6, 7, and 8 selects the desired subrange between 10 kHz and 10 MHz, as detailed in the Harris HA7210 specification sheets. I used three crystals, which are selected by SW2. The frequencies of these parallel mode crystals can be anywhere in the bands you want to check, from 160m up through 40m. This means that any convenient junk box or low cost surplus parallel mode crystals can be used—for example, the prototype used 1 MHz, 1.850 MHz and, 3.5860 MHz. These were all HC49U type crystals.

This is a small gadget, so find something small in which to build it. Any of the common mini-boxes are suitable. The supply voltage I used was +6 volts DC, supplied by four AAA batteries in a battery holder. The consumption was between 450 and 800 µA, depending on

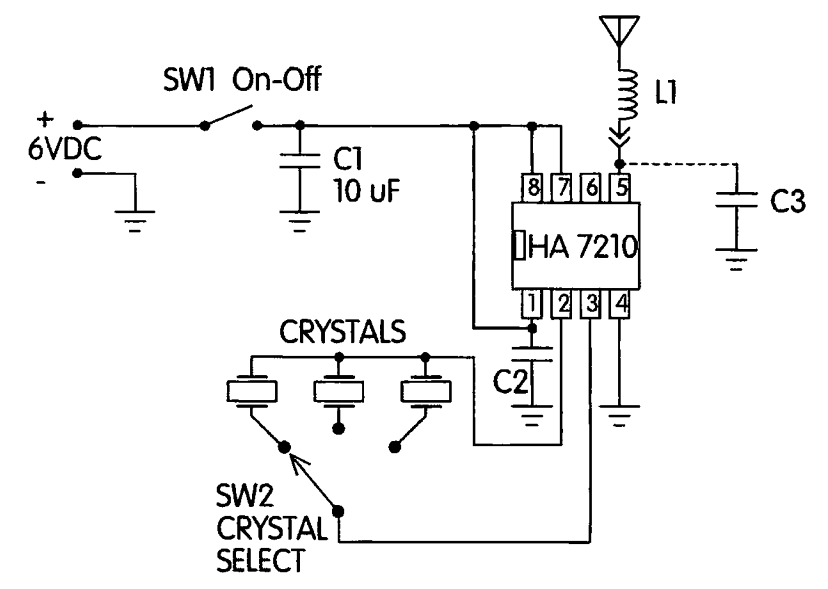


Fig. 1. The circuit.

Parts List

IC	HA7210P - Harris semiconductor
Socket	Eight-pin socket for HA7210P
SW1	Mini-toggle on/off switch
SW2	One-pole/three-way small rotary switch
Crystals	160m, 80m, and 40m (HC49U okay)
C1	10 µF capacitor
C2	0.1 µF ceramic capacitor
C3	4.7 to 30 pF, if required
L1	1 mH small RF choke
Plug	Phono plug with plastic case
Jack	Phono jack
Box	Your choice
Whip, battery holder, etc.	

the frequency and the output loading. Make sure that the leads to C2 (0.1 µF) are as short as possible, and use a plain perforated board to avoid any possible ground plane effect you might get with a copper-clad board. Otherwise the layout is not critical. In the unlikely event of instability, add C3, trying from 4.7 to 30 pF with short leads. The oscillator will only radiate for a few feet so it won't cause QRM or TVI. If you need a stronger signal, use a longer whip. In my work with loop antennas I rotated them and plotted the signal strength. With fixed antennas you move the oscillator around the antenna in a circle while taking field strength measurements for your plotting points.

This new IC is well-documented by the manufacturer. Ask Harris Semiconductor, Box 883, Melbourne, FL 32902, for copies of their "BA7210 Low Power Crystal Oscillator," File No 3389.3, and their Application Note AN9317, "Micropower Clock Oscillator and Op Amps provide system control for battery operated circuits." 73

NEVER SAY DIE
Continued from page 39

will be like in a thousand years. Ten thousand? A hundred thousand? A million?

Our first civilizations didn't get started until about 5,000 years ago, and I'll have more to say about that when I get Sirius.

Is it even remotely possible that some new communications medium will be developed that we don't even suspect today? Or perhaps, like telepathy, that we do suspect? One that doesn't have the bandwidth, interference, power, and time constraints of radio?

It seems to me that radio communications is just a passing technology that will eventually be replaced by something substantially better. It's a phase that many civilizations will go through for maybe a hundred years or so of their existence. Thus, trying to find worlds which are advanced enough to use radio, but have not yet moved on to better communications systems, a matter of perhaps a couple hundred years at best, out of millions, seems like a huge waste of money. We might do better to invest our efforts in researching other communications systems.

If, for some reason, you have some doubts about there being alien civilizations which have visited earth, then you are in serious need of some reading. Erich von Däniken in his *Chariots of the Gods* makes a good case for prehistoric alien visitors. As does Graham Hancock in his *Fingerprints of the Gods*. Now I'm reading *The Sirius Mystery* by Robert Temple. Maybe you've seen the TV exposé program on the Dogon tribe in

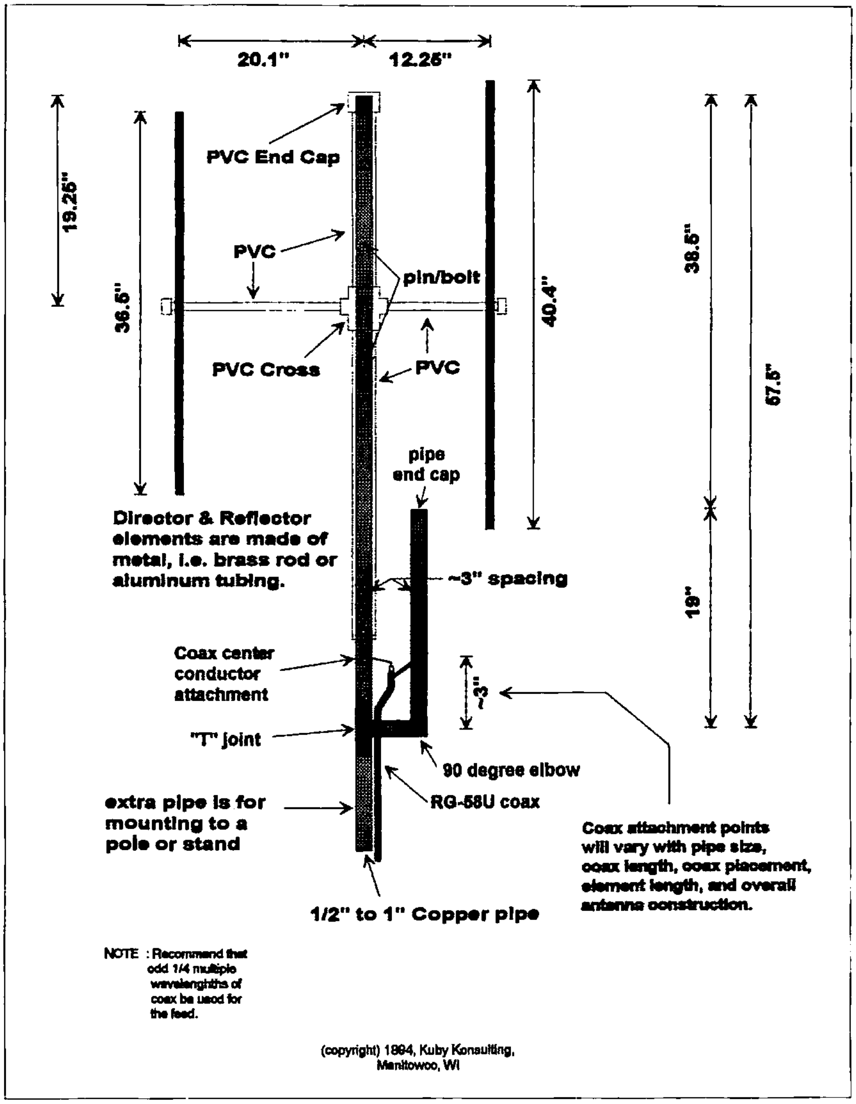
Updates

A Big Blushing OOPS!

You may have wondered, while reading N6JSX/9's article "The 'J' Antenna" in the August issue, what you were supposed to be looking at. Well, the gremlins and goblins that frequently throw parties at our production outsourcer's place seem to have slipped the illustration of the J-Pole, that was the whole focus of the piece, back into the folder without its being placed. We are abject.



More Power?

An "oops" note from William Jacobs WA8YCG about his article "Economic High Current Power Supply" which appeared in the June 1996 issue. Please note that in the parts lists and on the schematic, both appearing on page 52, R3 should be **3.3k**, and R4 is **750Ω**. Bill also wants to thank all the readers who have written with encouragement and good wishes.

Ham Shack Unplugged

If you happened to be floating around in cyberspace recently, perhaps you came across those three runaway words that escaped from our mainframe just before we sent the July issue off for printing.

Refer to Frank Brumbaugh's "Ham Shack Test Equipment" which starts on page 10 of issue #430. On page 83, in the second column, about two thirds of the way down, there is a space just big enough for the words "plug-in units." Coincidentally, those are the exact words that should be in that empty space.

A Picture's Worth a Thousand Credits

The photo of the CMOS Super Keyer 3 on page 80 of the July '96 issue should be credited to Marshall Emm.

Saving Ourselves From Ourselves

It's called getting involved.

Charles M. Seay, Sr. KN4HL
106 South Main Street
Dickson TN 37055

My license and yours were issued under Federal Commission Rule 97.1 in recognition and enhancement of the value of the amateur radio service to the public as a voluntary noncommercial communication service, particularly with respect to providing emergency communications.

Sometimes we forget that after receiving our licenses. We have a tendency to get caught up in our own little part of the amateur spectrum, not bothering to try new things. However, these licenses are a grant from the government and we need to channel more of our individual and club activity into public service.

Interface with your community

One of the reasons that amateur radio has not been growing as fast as it could is that licensees have not made themselves and their clubs as visible to the public as they should. Only occasionally do you see an amateur call plate on an automobile. Most states will provide an amateur operator with a callsign plate (upon proper application) for no more than a regular license plate costs.

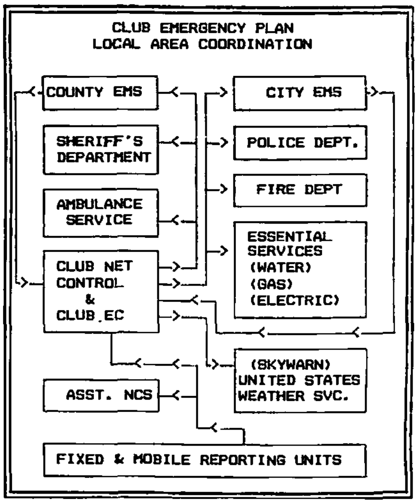

Fig. 1. Local amateur radio club organizational and information flow chart. Your own club's emergency plan should be reproduced and given to each department head in your community (this chart is from "Organizing a Club Emergency Plan," published in Radio Fun, *June 1993).*

Amateur radio clubs start and then fade because club activities are rare or nonexistent. Members need activities to keep them motivated. Club members should make every effort to build working relationships with the local Sheriff's Department, Police Department, county and city emergency medical service, ambulance service, water, gas and electric departments and especially the local Emergency Management Agency.

"When one department has developed a relationship with your club, others will follow."

It will take hard work on the part of club members to win the confidence of the department heads. These people instinctively start protecting their individual turf when outsiders offer help. Be patient; if approached in the right way these folks will become appreciative of your efforts. Sheriffs' and Police Departments may be the most resistant to your efforts, but don't give up. Police Chiefs must be reassured that club members are not trying to be police officers. Approach the Chief with the idea of club members being a mobile neighborhood "watch on wheels." Invite the Chief or Sheriff to a club meeting two months before Halloween and offer to help Halloween night to crack down on vandalism, reckless driving, or other activities that the Chief or Sheriff may suggest. If he accepts your offer, plan your activities in conjunction with his office and follow his instructions explicitly.

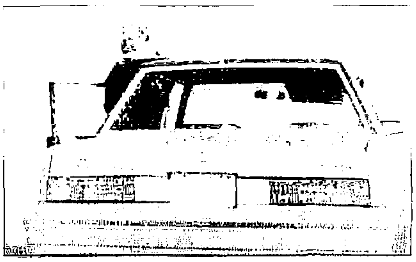

Photo A. Joyce Seay KC4RNX (now AD4EX), on patrol with "Operation Goblin" in association with the local Police Department. At Halloween each year, most Police Departments welcome extra eyes and ears to prevent vandalism.

When one department has developed a relationship with your club, other departments will follow.

Be ready

Let the emergency management agency in your area know that club members are able, willing, and ready to answer a call for help in an emergency. This might include storm damage surveys or providing communications at emergency shelters.

Each club should develop an emergency communications plan, including an information flow chart like the one shown in **Fig 1**. Make copies of this chart and add a brief description of the club capabilities in the event of an emergency. Deliver these charts to each of the department heads and invite them to a club meeting. Even if they don't use club members in their operations, the question and answer session will make a superb program for that meeting.

Inactivity in amateur radio clubs is a disease that is completely curable if club members will just get off their duffs. More people rust out than wear out—let's scrape off the rust and get involved! We owe that much to our communities. 73

NEVER SAY DIE
Continued from page 43

Mali. Their religious rites are based on a visit from aliens about 5,000 years ago. The aliens were from a planet circling Sirius B. This is a star that was first spotted in 1970. It's a white dwarf that circles Sirius A, which is a very bright star. Well, you really ought to spend the $17 for the book and be amazed at how closely the Dogon tribe's stories tie in with facts discovered only recently.

There's a strong suggestion that these visitors may have helped mankind start our first civilizations, which somehow sprang up almost overnight in several places ... like Egypt and Sumer. The more you read about the pyramids, the more believable is this story. How about temples built so Sirius A shines down a long corridor on New Year's Day to spotlight the altar? The Temple of Isis at Denderah is a good example. Coincidence, right?

Are the thousands of stories of current alien visits all hokum? And if so, why is our beloved government going to such extremes to shut up people who report having seen them?

Well, whether aliens are here with us now or not, it seems like a big waste of money and time for us to be listening for alien radio signals. Maybe we'll hear a spark rig from some new apes on the block.

W4JJ

A reader pointed out that Jerry Freeman's call was W4JJ, not K9AAH (in a May letter). Yes, I should have caught that! But I hadn't heard that Jerry, shortly after retirement, died of a brain tumor. I've had several friends die of brain tumors, so I've been particularly interested in reading books which go into how to avoid them, and how to get rid of them without the usual medical procedures. I sure wish Jerry had let me know that he had a problem. He was only 63, so he could have had at least another 40 healthy years or so ahead of him if he'd taken enough interest in his problem to discover some of the powerful alternatives to the medical industry's usual approaches. You just don't get cancer if your immune system is strong.

More Celebs

A note from my old friend Tim Chen BV2A, whom I used to visit every year when I was leading tour groups to the Asian electronics shows, reminds us that AC3PT, the King of Sikkim, should be added to the celebrity list. And Tim also points out that our DX Dynasty Award should now recognize Pratas Island BV9P. The rule is simple for the DXDA award: Any country accepted as such by a national ham organization of any country is recognized for DXDA credit. This makes it possible for someone with little else to do to work 400 countries.

In all fairness, I had a lot of fun working 350 countries. It took me a couple of years. But I find I'm a "been there, done that" person, so I don't have a lot of enthusiasm for repeating things I've already done. Like one time for visiting most countries is fine. Maybe that's why, when I start a new magazine, I'm ready to sell it once I have it going well. A sort of seven-year itch thing, maybe.

Ted Chernin KH6GI faxed me a reminder that Wells Chapin W8GI had an article in the May 1969 *73* on ham celebrities. Ted must have a lot better index of the back issues than I.

NASA Update

My review of René's *NASA Mooned America* (in the June issue), wherein he made a case for the whole Apollo moon program being a hoax, á là the movie *Capricorn One*, infuriated some readers and got a bunch more to read the book to see for themselves. This has kept René busy having more books printed for us, while keeping an eye out for CIA spooks.

A reader I've known and trusted for many years wrote to tell me about an experience he had while working at the NASA Goddard Space Flight Center in the mid-'70s, maintaining the computers and telemetry equipment. He was surprised at how antiquated the computers were, being mainly Univac M642Bs, an early generation which had been resurrected from Navy ship fire control systems. Data storage was on paper or mag tape.

One day he needed a mag tape for some work and none were available, so he poked around and found an old unmarked tape in a storeroom that looked okay to use. But when he checked to see what was on it he found it to be the info used to drive the displays in the Operations Control Center during an Apollo mission. It was a tape which was normally run during a mission to log all activity to tape for later analysis. So what's the big deal? The tape's creation date was well *before* the mission took place! However, considering how the system was set up, he knew it was impossible for a mistake to have been made in the creation date.

In addition, he noticed that the tape was too clean to be a legitimate log tape. Normally, the log tapes have a lot of data on them from the unexpected things that happen during "real world" operations. That's the purpose of the log tapes. Nor was it a simulation tape; those were only a few minutes long and not an entire mission tape such as he'd found.

Having done an in-depth report on that Apollo mission in school, he knew the dates were wrong. This has been worrying him ever since, but he prudently kept quiet about it.

Other than a few letters from angry readers who are convinced that our beloved government wouldn't lie to us, and who have no intention of reading the book, I haven't seen much to refute the 30 points René makes. I want René to be wrong, but he makes a very solid case. The book is $25 (plus $5 s/h) from Radio Bookshop.

Many of the readers who got his *Moon* book have since ordered his *Last Skeptic of*

Continued on page 48

Never Say Die

Continued from page 47

Science book (also $28, including shipping). A couple readers have raised questions, but René has done his homework thoroughly, so nobody has stumped him on anything yet. No ice ages? Ridiculous! But René's explanation fits the facts and the whole idea of ice ages doesn't.

Pirate Caught!

During the recent Sea-Pac convention in Oregon the Phantom Amateur Radio Group (PARG, from Beaverton) was enjoying their annual bonfire on the beach when one of the members, who was monitoring the police channel, heard someone break in cursing. They quickly turned on their direction-finding equipment and within five minutes had located the pirate at a nearby motel. They could see him on the third floor balcony talking into his HT. Another member stopped a nearby police cruiser and explained that three club members were on their way to the pirate's motel. Just before they arrived they saw the pirate come down the stairs and run off. A couple hours later the interference started again so the police went to the room the members had pointed out and caught the chap in the act. The pirate is reported to be KE6VNU, who was there for the convention. It turned out that he'd been released from jail just shortly before this incident. Yep, for causing malicious interference in his home area.

Now, will the FCC lift this guy's ham ticket?

Calling Channel

A letter from Ralph Gaines WL7DU makes a good point. During an ARRL contest he was trying to maintain contact with a vessel in distress, only to have the boat's weak signal clobbered by contesters. My suggestion is for contest sponsors to set aside parts of each band as out-of-bounds for contesting. Further, maybe it's about time to establish a "calling frequency" on each band where emergency traffic would have priority, but which could be used for establishing contacts the rest of the time. It would be a good channel to monitor, with callers checking in, as we do with repeaters. And once a contact is made, the QSO would move to another channel to continue.

On 20m we might set aside 14.275-14.300 for non-contest contacts, with 14.285 as the calling/priority frequency. 14.275 would be better, except that it's used for blind broadcasting many hours of the day by K1MAN. Or do you have a better suggestion?

Talk Radio Lives!

Art Bell W6OBB called and asked if I would be a guest on his radio talk show again. Sure. I knew I'd get another big pile of mail like last time, but the upside was that I would have an opportunity to talk about ham radio on a program with tens of thousands of listeners.

The interview was on Friday night. On Monday morning a stack of letters 18" high arrived. And it kept up like that for almost two weeks before slowing down. Two months later I was still getting a dozen or so letters a day!

Art and I talked for four hours. His show is rated #1 in Los Angeles, Seattle, and many other markets, so it has a humongous audience. My first interview six months before brought over 2,500 letters. Friends in the Denver area said that I was on for six hours—the four hours I talked live, plus a repeat of the first two hours. And the program was repeated by many stations over the next couple of days.

Many of the letters from regular Art Bell listeners said this was his most interesting show ever. With the Dayton HamVention no longer asking me to talk, I needed confirmation that I'm still interesting. Well, I can understand the pressure the HamVention must be under from the ARRL, which views me not as a fellow ham or entertainer, but as a business competitor. And money rules, both in Newington and in Dayton.

Art and I talked a lot about how much fun we've had with ham radio. But I also couldn't help mentioning my 28-page list of 83 books you're crazy if you don't read, the Bioelectrifier, cold fusion, the René book about NASA, and so on. You know, all that stuff you grumble about me writing about in my editorials. I didn't even have time to get into dowsing, UFOs, contactees, reincarnation, and weirdo stuff like that.

Picture 300-500 letters a day to be opened, read, envelopes addressed, a 12-page list of my available booklets stuffed, and a quick answer to questions added. Well, if it'll help get us a few more hams, it's worth it. And I think it will help because subscriptions to *73* are pouring in. Yes, I did most of the work myself. In case you wondered, AM radio is alive and well. I wish I had time to do more interviews like that. I also wish I had the time to personally answer more of the letters. But if I can get people to start reading some of the books on my list they'll at least have the information it takes to live longer, much healthier lives. However, I've found that health is way down on the list of important stuff for most people, at least until something goes so wrong they have to go to the doctor—who looks them over and then leans back and says, "Uh, o-oh."

Art sure has a lot of listeners. The mail poured in from Hawaii, Alaska, St. Thomas, and all around the country. All 50 states!

One thing surprised me. Though I did get a few letters from hams, when I think of the thousands of people I know personally through my work in the ham field, computers, the music industry, and so on, none of the mail came from people that I knew. Well, 350 million is an awful lot of people. Now, how can we reach more of them with our message of how much fun and adventure we have available for them in amateur radio?

Missed You at Dayton

Not being asked to speak, plus deciding not to be tied to a booth, and not being able to get away for five days anyway, I skipped the HamVention again this year. That's maybe three skipped over the last 41 years. Well, it's turning more and more into a computer flea market, like most other hamfests. I haven't been a computer hobbyist since the TRS-80, one of the first integrated microcomputers, came out in 1977. I've been a user. I got a TRS-80 Model I the day it was introduced. And their Model 100 laptop the first day it was available, in 1983. But then Radio Shack did their $50 billion-plus screwup, dropping from 40% market share to around 1%, so eventually I replaced my trusty old 100 laptop with a Macintosh PowerBook.

How was Dayton for you this year? Were the talks exciting and well-attended? What did you buy? What did you see that was new and interesting? What did I miss?

1960, When *73* Started

With my 74th birthday on September 3rd, and this issue winding up 36 years of *73* (will I make it to 40 years?), I couldn't help remembering 1960, the year I started it.

That was an eventful year for me. It started off briskly when I was fired on January 5th as the editor of *CQ*. Well, things had started destructing along about Christmas. A little matter of some differences with the publisher. Like he owed me a year's pay. And I'd discovered he was a year behind on paying my authors for articles, and a year and a half behind on paying my columnists. Worse, my assistant editor dug into the circulation manager's desk one night and gave me a copy of the actual paid circulation of the magazine, which was less than half of the sworn statement circulation figures. In the publisher's desk he found a financial statement which showed that *CQ* had made $100,000 net profit in 1959, most of which had gone to pay for the publisher's new 58-foot yacht, which he had taken as a "business expense." Then, at Christmas, he gave me a $5 Christmas bonus, "wishing it could be more."

But he'd let me know in many ways that as the only outsider on the staff I really shouldn't count on a future. It was a family-run business and I had been hired at a desperate moment when the previous editor quit and *CQ* was losing a lot of money.

After being fired, I tried working for an ad agency. But my love was amateur radio, so I decided to take a gamble. I sold everything I owned of value and got together just enough money to print the first issue of *73*. Well, that's what entrepreneurs do.

At the same time I was working with the ARRL Hudson Division to put on a New York City ham convention. Chet K2EAF, a manufacturer's rep, and I sold all of the booths and helped with much of the organizing of the convention. Chet and I were disappointed at the convention banquet when Harry Daniels W2TUK took credit for everything, never mentioning our part. Honors apparently were very important to him, earned or not.

Also that year there was an article in *The Village Voice* newspaper about Mensa, a high-IQ club in England. They were looking for American members. I'd had my IQ checked in college so I knew I should qualify, so I sent for their test and became American member #15.

A few weeks later Peter Sturgeon, the brother of well-known writer Ted Sturgeon, called and asked if I was interested in forming an American Mensa group. Sure! So he, two other members and I met at his apartment in downtown Brooklyn and American Mensa was started. Since I had a mimeograph and an addressing machine, I became the first secretary. I got the list of people who had qualified from London and sent out meeting notices every month. The next two meetings were held at my house in Brooklyn, then we rotated to other members' homes. I decided to get the heck out of New York in June 1962, moving to New Hampshire, where I was the Mensa local secretary for many years. Peter later moved to Switzerland. The other two chaps who were there at the beginning disappeared. One was a schoolteacher and the other a reviewer for a book publisher.

If I'd stayed in New York I think Mensa would have turned out much differently. My goal was to get the members together in groups to brainstorm ideas to help solve our country's more serious social problems. I wanted to put those IQs to work, not just have a snob club. Mensa turned out to be totally useless and a sad waste of a potentially powerful resource. Well, that was my fault for moving to NH.

In addition to helping with the Hudson Division ARRL Convention and getting American Mensa started, I was also president of the Porsche Club and quite involved in organizing car rallies and club visits to the factory in Stuttgart to pick up new cars. I got the program started in 1958 and it was a great success. A hundred and fifty of us flew over on Lufthansa, picked up our new Porsches in front of the Solitude Castle, and then the

Houston, we have a problem—OSCAR 13's last Field Day.

Time is running out for AMSAT-OSCAR-13. While the satellite was online and working great for Field Day (June 22nd and 23rd) this year, next year it will only be a memory. Reentry should occur in mid-December. Many changes to A-O-13's orientation and operating schedule will begin soon, as ground-control stations stabilize the craft to prolong its useful life in the sky.

During Field Day 1996, most stations in the U.S. had only a few hours of access to the satellite in the early hours of Sunday morning, but it was worth it. The satellite was aimed at the center of the earth while at apogee (the highest point of its elliptical orbit), and conditions were optimum.

A-O-13 was originally scheduled for a major orientation change just before Field Day to keep the solar panels aimed at the sun. Because of atmospheric drag around perigee (the orbit's low point), the orientation had shifted on its own to a point that was acceptable for a few more days. The radical orientation change was not needed until after Field Day, so signals from the satellite were stronger than expected for the contest period.

"In early November things will begin heating up on board the satellite."

An explanation of the orbital mechanics and physics involved with the demise of A-O-13 requires a lot of math and interpretation. James Miller G3RUH has covered the topic in detail, and the information can be found via the Internet at the AMSAT ftp (file transfer protocol) site. The URL (Uniform Resource Locator) for A-O-13 information is *ftp://ftp.amsat.org/amsat/satinfo/ao13/*. Published articles by James can be found at *ftp://ftp.amsat.org/articles/g3ruh/*. For our purposes, it is sufficient to simply describe some of the events that A-O-13 will experience until its end in December.

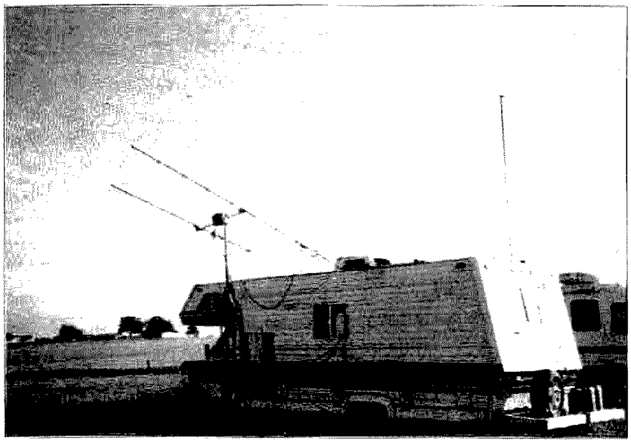

Photo A. The K5DX analog satellite station was set up in this RV at the W5SJS Ranch in South Texas for Field Day 1996.

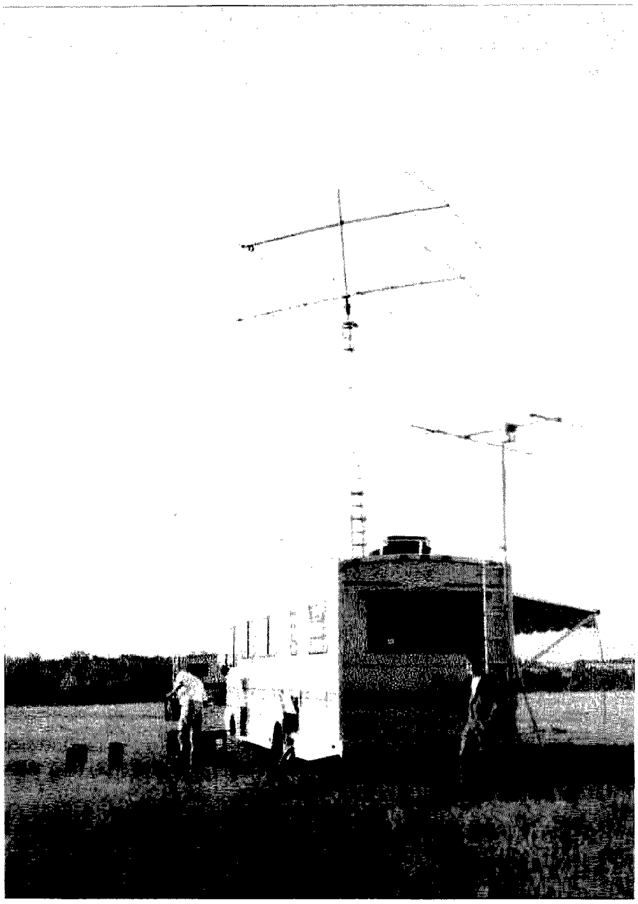

***Photo B.** N5DC and WA5ZIB outside the K5DX Field Day HF-SSB and digital satellite RV on the W5SJS Ranch.*

Subtle orbital changes began to occur in January of this year. The Mean Motion (number of orbits per day) started to decline due to atmospheric drag. By April, the satellite was losing about 80 ms per orbit. This may not sound like much, but old element sets begin to produce inaccurate computer predictions, and the problem gets worse each month. As with a low-orbit satellite, new element sets should be used whenever possible. The perigee was down to 300 km in May. By October it will be about 160 km.

From an operational point of view, normal A-O-13 orientation to aim the high-gain antennas at the center of the earth at apogee is ALON/ALAT = 180/0. Due to the atmospheric drag and heating problems that begin in the fall, the satellite orientation will be set to ALON/ALAT = 90/0 beginning in late August or September. This means that the satellite's high-gain antennas will be aimed away from users almost all the time. Heating problems will be minimized and orientation problems due to drag will be stable. The mostly-flat motor side of the satellite will be facing the atmosphere around perigee. The high-gain antennas and solar panels will not be "into the wind" with their unsymmetrical proportions.

The omnidirectional antennas and Mode-B transponder (70 cm up and 2 meters down) will be activated full-time when the orientation changes

are implemented. The omnis will be correctly aligned for good use both at apogee and perigee.

In early November things will begin heating up on board the satellite. At the end of May, the solar panel temperature was about 53° F. At the beginning of November the temperature could be as high as 100° F around perigee. The reorientation to ALON/ALAT = 90/0 will keep this down a bit, but by the end of November, temperatures could go as high as 480° F. Thermal cycling between the hot time around perigee and the colder periods during the rest of the orbit will likely cause the panels to crack. Solder may have melted by this time and the transponders may be fried.

helium balloons for late-night activity. The motor homes (with air conditioning and microwave ovens) and generators performed flawlessly, and contacts were fast and continuous at the voice, CW, Novice, and VHF/UHF positions.

Two satellite positions were added to the extensive array of stations this year: one for analog (voice/CW) satellites under the American Radio Relay League rules, and another for digital satellites and the AMSAT Field Day rules. All of the available satellites and modes were pursued, with only a few exceptions.

More on Field Day

AMSAT-OSCAR-10 has been in orbit since 1983. This

"The ARRL rules do not recognize digital activity through these satellites, but the AMSAT competition counted every Field Day message download and upload as three points."

As we approach the end of the useful life of A-O-13, many stations will be monitoring the telemetry. This will provide insight for future spacecraft designs, in addition to the educational potential. Don't forget to make some contacts via OSCAR-13 before the conclusion of the A-O-13 story.

The K5DX Field Day

The Houston AMSAT group went out with the Texas DX Society this year. The TDXS folks always have an incredible array of antennas, radios, and operating positions for HF work. Large yagis for 10 meters through 40 meters were raised on trailer-mounted towers. Guy wires were pressed into service as inverted V's for 75 and 80 meters, and a 75 meter delta loop was lifted by

13-year-old satellite is still performing very well. The computer memory is dead and the batteries are no longer functioning, but when the satellite is in sunlight the solar panels provide power and the Mode B transponder works well. Activity is usually very light, but for Field Day contacts were brisk and the downlink passband sounded like 20 meters. Signal strength was not as good as A-O-13, but after November, A-O-10 may be the only available high-orbit hamsat available for use.

The low-orbit RS satellites were packed. RS-10 with its Mode A transponder (2 meters up and 10 meters down) provided many quality contacts. Signals were strong and contacts were easy. RS-12 was active on both Mode K (15 meters up and 10 meters down) and Mode T (15 meters

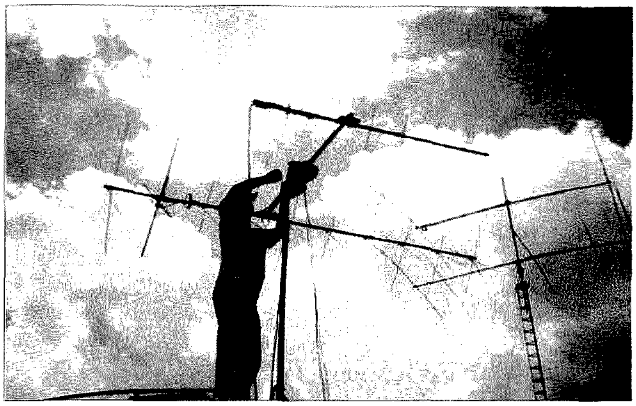

Photo C. *Mike WA5TWT finishes installation of the VHF/UHF array at one of the K5DX hamsat stations.*

up and 2 meters down). Mode T operation was easier for many participants. Interference from nearby 10 meter Field Day stations had no effect on the 2 meter satellite downlink. RS-15 was operational for Mode A activity. Although the downlink signals were weak, passes were long for a LEO (low-earth orbit) hamsat and many successful Field Day contacts were logged.

During the daylight hours of Field Day, AMSAT-OSCAR-27 provided FM QSOs for those equipped for Mode J (2 meters up and 70 cm down). The satellite is not activated for nighttime passes. Since this satellite provides only a single voice channel, it sounded more like a local FM repeater with everyone trying to talk at once.

Fuji-OSCAR-20 was available for voice and CW contacts. The Mode J analog transponder offered good QSOs, even though the Doppler shift was a persistent factor. A new Fuji is scheduled for launch in August. It will have an analog transponder in addition to 9600-baud packet.

While the 1200-baud digital satellites like AMSAT-OSCAR-16 were active for Field Day, the 9600-baud birds like Kitsat-OSCARs-23 and 25 had more traffic. UoSAT-OSCAR-22 also carried digital Field Day messages. The ARRL rules do not recognize digital activity through these satellites, but the AMSAT competition counted every Field Day message download and upload as three points.

Thousands of amateur-radio stations listened patiently

Photo D. *Andy WA5ZIB gets ready for a Kitsat-OSCAR-25 pass at the K5DX 1996 Field Day site in South Texas.*

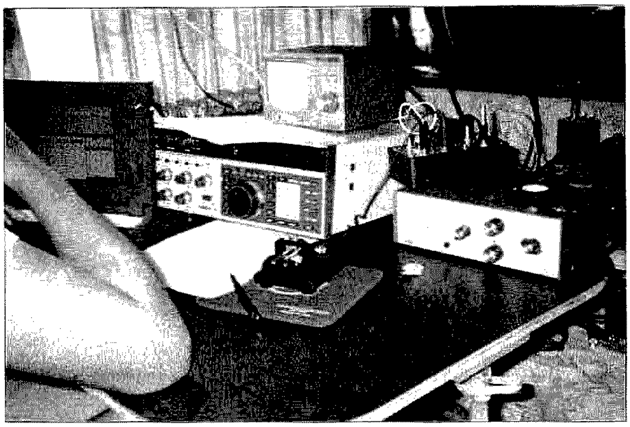

Photo E. The K5DX HF-CW station was simple, yet effective, with over 100 contacts per hour.

Photo F. An experiment worth trying: The K5DX HF team suspended an 80 meter delta loop with balloons from their South Texas Field Day site.

for the space shuttle. Mission STS-78 was up, but nothing was heard on the 145.55 MHz downlink. Shuttle experiments took precedence during the contest period. Hundreds of enthusiasts made voice and packet contacts during the days that followed Field Day, but not during the weekend.

"It was also a reminder to the long-time satellite enthusiasts of how much fun the hamsats are to work."

Field Day 1996 via satellite was an exciting event. Although it was the last for A-O-13, it provided many newcomers with an opportunity to experience satellite communications. It was also a reminder to the long-time satellite enthusiasts of how much fun the hamsats are to work. In the months ahead we can monitor the demise of A-O-13 and renew activity via A-O-10, F-O-20 and the many other satellites still in orbit and working great.

Massillon OH 44646

As QRP rigs become even more complex, using perfboard for their assembly has become the exception rather than the rule. Most of today's circuits require the use of a PC board. Also, you can just about forget the fingernail polish and resist pens. It's nearly impossible to lay out a PC board by hand using today's miniature parts.

By far, the easiest way to generate a PC board is to use one of several computer CAD programs. These programs are nothing more than fancy drawing software on steroids. I've used several in my time and currently use the DOS based CirCad.

Instead of focusing on how to make a PC board, I thought I would take a different approach. Laying out the PC board is almost as complex as the circuit you're building.

Get your ducks in a row

After you have a working schematic, and your project works, the next step is to get all the parts mounted on a circuit board. I find it best to start off with a sheet of paper and a pencil or two. Oh, and a *big* eraser! This first step lays the groundwork for the computer. It also forces you to show, on paper, the input and output jacks required. If you need an antenna jack, power or speaker output, now is the time to put those down on paper. Also, if you plan to use a part with a unique footprint you need to show that location on your work sheet. Let's say you're planning to use a BNC right-angle connector. Place this part on your work sheet in the general location you desire. You might also want to make a mental note that you can't locate parts under the BNC connector.

Move the parts around, trying to get everything connected with the shortest possible routes. But don't worry about all the connections; we'll let the computer work on those. Sometimes you can actually lay out the board to closely follow the schematic. The trial on paper give you a idea of how the PC board will look when it's finished.

Net lists

Most of the high-end PC board drafting programs include a sub program to generate net lists. To do this, you must first draw out your schematic within the CAD software. Sometimes the schematic drawing program is separate from the CAD software; in other cases it is built-in.

When you are sure the schematic is correct, you generate a net list, which contains all the connections you have drawn on the schematic. The net list knows that R4 pin 1 is connected to pin 2 of C11, and that pin 1 of C11 goes to the base of Q4. The net list then becomes the "rule" for checking what you have on the schematic and what you will do on the PC board.

With net list in hand, you can start to lay out the board. With CirCad, you input the net list for your project. The net list also contains all the required outlines for the various parts.

Since the net list imported all the outlines for the parts, you're ready to begin. Most people will put tack marks to mark the corners of the board. You can also draw an outline the same size as the finished board. I do neither—I just jump in and start moving parts around.

It's best to use standard spaces. I use .1 mil grid for all parts, then drop to .025 mil if need be. Always use the "snap to grid" option. It may be called other names by different programs, but it does the same thing. With "snap to

grid" on, you can drop a component on the board and the software will automatically place it on the closest grid point.

If your layout requires odd-sized parts or special connectors, use your paper work sheet and place those parts on the board. That done, you have several options, depending on the power of your PC board software.

If your software generates net lists, then it will do what is known as "rats nest" wiring. Here the software will connect all the different points as required by the net list. Since the lines shown are not actual copper traces, they cross each other back and forth, hence the name "rat's nest" wiring.

The purpose of the rat's nest is to allow you to move the parts about, all the while connected to the rat wires. You move and rotate parts so you have the shortest and best routes for each signal.

Routing and traces

Once you're happy with the layout, it's time to route the board.

I've gotten lazy with CirCad: I use the autorouter all the time. You can route the board by hand; however, if your software comes with an autorouter, by all means use it. Autorouters are not perfect, but they can help you design your board.

The autorouter may route your board correctly according to the net list, but the end result may not be the best design. Most autorouters that I have used are not smart enough to know the difference between a VCC line and a signal line. Also, if your project has an RF section, then the autorouter won't route the traces to ensure stability in this section. A good example is the emitter lead of a transistor used in the PA stage of a QRP transmitter. The autorouter may have in fact routed the emitter lead to ground, but the trace may be to one of several grounds on the board.

To ensure a stable PA stage, the emitter must be grounded using as large a trace as possible. This trace must also be as short as possible. The same problem occurs with VCC lines and heavy current. Large short traces are necessary to ensure proper operation. The collector of that power amplifier must have its trace wide enough to handle the intended current required by the transistor. But at the same time, the trace must be short and as direct as possible to avoid adding unnecessary inductance.

You can sometimes ease routing time by using copper pouring. The CAD program allows you to "pour" copper into large areas of the board. Copper pouring is great for creating a ground plane in selected locations.

As far as trace width goes, I autoroute with 10 mil traces. These give the autorouter the easiest way to make connections. After the autorouter is done, I edit the lines, making them wider than the 10 mil traces. I like to use 20 mil width trace between signal pads, and up to 250 mil width for VCC traces. I like wide traces on my PC boards. Perhaps it's a throwback to the days of resist pens and nail polish—in the old days, a thin trace was quickly etched away with the rest of the copper!

WB8VGE's tips

I know I don't know everything about laying out a PC board, but here are some tips I've picked up along the way. Perhaps you can use a few of these next time you lay out your PC board.

We place screw holes in the board so we can mount the board. Don't forget about the heads (or nuts) that will be inside those holes. If you place traces too close to the mounting holes, the screw head may in fact short the traces to ground.

There is the same amount of copper on the top as on the bottom. Unless you have a really simple project, think double-sided PC boards, even if you can't afford a double-sided board with plated-through holes. Lay out the board so connections on both sides of the board can be made by soldering a resistor lead on both sides. This will allow you to use sockets under the ICs, while using a board without plated-through holes.

If you do use plated- through holes, remember to take into account the .003 inches worth of plating inside the holes. If your mounting screws just barely make it though the holes now, after the plating, they may not fit! I use .038 inch holes, which after plating leaves me with .035 holes. This is my standard for resistor leads. You can use smaller holes, but the .038 size leaves me plenty of wiggle room in case I need to remove the part. The vacuum desoldering tool works much better with the larger hole size.

Watch out for capacitors. It's not so much the lead spacing, but the actual physical size of the caps that can throw you a tomato worm. A .47 mF capacitor has the same .2 mil lead spacing but may be nearly four times as fat, so the guy won't fit in between the rest of the parts.

"Here are some tips I've picked up along the way."

Keep an eye out for any kind of connector. It's easy to crowd the connector by getting parts too close to it. Really ruins your day when the first prototypes come in and, after you have the board stuff, you find out you can't get the connector's plug on!

Paper is cheap! I use paper from my recycling box that has been used on one side. Turn the paper over and run it through the laser printer one more time. Print all the time and as often as you can. The board looks a lot different on paper than it does on the screen. Check for traces that look just a tad too close. These may cause you trouble down the road.

Some software has the correct drivers to output to a color ink jet printer. That really makes it easy to check both sides on a double-sided board with one printout.

Don't worry about getting the board as small as you can. I know some of the QRP rigs have a built-in "cute" factor, but for first-time PC board makers, don't try for sub-miniature designs.

I'm out of room for this month. We'll take a break and pick up this thread in November. Next month, October, will be rather special. The October issue will mark ten years of this QRP column. Please join me at a look back at 10 years of "QRP."

NEVER SAY DIE

Continued from page 49

famous Porsche racing team taught us how to race them on the Solitude race track. Wow! From there we drove to Locarno, where over 700 Porsche owners from all over Europe gathered for a huge party.

Yes, 1960 was an eventful year. I wonder how many of you still have that original October 1960 37¢ issue? The cover cartoon was drawn by Bandel Linn K8LAP, who had a daily talk program on WSPB in Sarasota, Florida, where I had been an engineer-announcer back in 1950.

Nostrums

Being fairly vigorous and having an obvious interest in staying that way, I've been delving into the "how to get or stay healthy" literature. What a mess! There are dozens (maybe hundreds) of books claiming to have found the secret of health. Lordy! And if that isn't enough, every mail brings a booklet or colorful brochure advertising still more ways I can achieve robust health. And each camp, like our welter of commercial religions, has a group of dedicated true believers.

I've been helped a whole lot by readers who have recommended books or health approaches they've found beneficial. At any rate, in my role as a reporter and pseudo-teacher, and with my doctor and professor caps in the drawer out of sight, I've been doing my best to sort out what looks scientifically reasonable and repeatable in the health and longevity field.

Yes, I know, you probably don't care how long you live. Or even how long or healthily your children live. You know you and they are slowly committing suicide, heading towards heart attacks, cancer or a nursing home, or both, but then so are most other people, right? So you'll just get angry with me when I mention that I've found some promising solutions to being fat (which makes you tend to get sick and die earlier than average), and I've also found that you're poisoning your body in a dozen or so ways.

There are some good reasons to believe that the Bioenergizer may help solve the fat problem. Certainly the Comby book will.

Carr's Corner

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041
E-mail: carrjj@aol.com

It is very difficult to get an antenna working properly without making some simple measurements. Although it would be nice to make azimuthal and elevation pattern measurements, those are beyond the reach of almost all of us. On the other hand, the "I worked [or heard] a guy on the other side of the world" type of measurement tells us little or nothing. Heck, during the peak of the sunspot cycle a breath of hot air on the antenna can be picked up on all continents. Little or nothing can be said about the antenna from working a single DX station. I recall one fellow back in the early 1960s (on the downslope of the sunspot cycle) who worked DXCC in less than a year using a 50-watt Heathkit DX-20 crystal-controlled transmitter feeding a three-band trap vertical. He made up for the lack of a loudenboomer blow-torch RF power amplifier and a large beam with more than a tad of operating skill.

There are some things about antennas that can and should be measured, however. For example, VSWR and the resonant frequency of the antenna are readily accessible. It's also possible to measure the impedance of the antenna feed point. Hams can measure the VSWR either with a special VSWR meter (often built into transmitters or antenna tuning units), or by using an RF wattmeter.

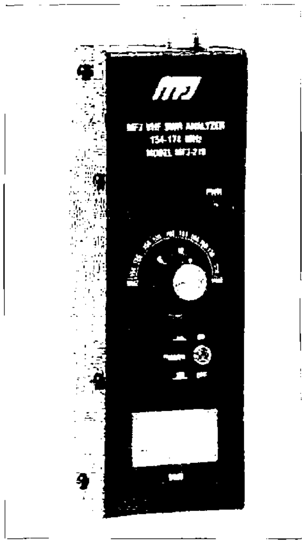

Photo A. VHF VSWR analyzer.

By stepping through the band and testing the VSWR at various frequencies, you can draw a VSWR curve (**Fig. 1**) that shows how the antenna performs across the band. The resonant frequency is the point where the VSWR dips to a minimum. You can use the resonant frequency to figure out whether the antenna is too long (resonant frequency lower than the hoped-for design frequency) or too short (resonant frequency above the design frequency).

But resonant frequency and VSWR curves are not the entire story because they don't tell us anything about the impedance presented by the antenna. You can't get the VSWR to be 1:1 unless the antenna impedance and transmission line impedance are the same. For example, a dipole has a nominal textbook impedance of 73 ohms, so it makes a very good match to 75-ohm coaxial cable. But the actual impedance of a real dipole may vary from a few ohms to more than 100 ohms—if your antenna exhibits a feedpoint impedance of (say) 25 ohms, using 75-ohm coaxial cable to feed it produces a VSWR = 75/25 = 3:1. Not too great. Measuring the feed-point impedance is therefore quite important to making the antenna work properly.

There are any number of instruments on the market that will aid in making antenna measurements. Some of them are quite reasonably priced (or can be built), while others are beyond the reach of all but the most ardent and well-endowed enthusiasts. In this column we will look at a newer breed of more universal instrument called the *SWR analyzer*.

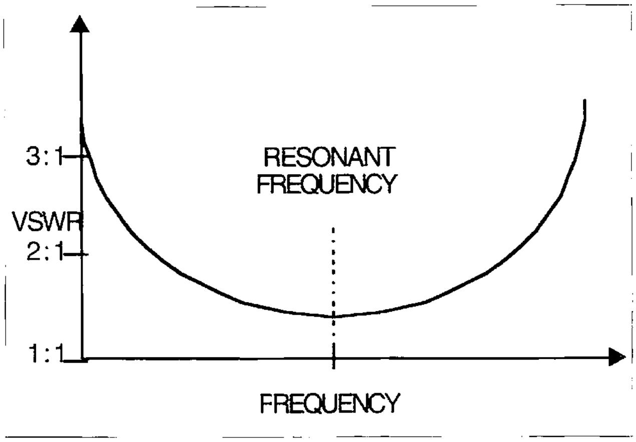

Fig. 1. VSWR vs. frequency curve.

VSWR analyzers

One basic premise in this column is that the instruments used for measuring VSWR must be accessible to people who don't have a ham operator's license,

> ***"Unlike many lesser SWR meters, this instrument is not fooled by antennas."***

as well as those who do (we must remember our SWL and scanner friends). Some of the instruments used by hams meet that requirement, but a relatively new breed of instrument called the SWR analyzer provides a lot of capability to the SWL, scanner operator and ham radio operator alike. It uses a low power RF signal generator and some clever circuitry to measure the VSWR of the antenna. One model also measures the feedpoint resistance.

The simple version shown in **Photo A** is for the high VHF band (154 to 174 MHz). It is a handheld battery-powered instrument made by MFJ Enterprises, Inc. (P.O. Box 494, Mississippi State, MS 39762). The meter reads the VSWR of the antenna at the frequency set by the TUNE dial. Alternatively, you can adjust the TUNE control until the minimum VSWR is found, and that is the actual (as opposed to desired) resonant frequency.

A somewhat more sophisticated instrument is the MFJ-249 (**Photo B**). This instrument combines a VSWR analyzer with a digital frequency counter, and operates over the range of 1.8 to 170 MHz. A bandswitch is set to the desired band, and then the TUNE control is set to the desired frequency. The meter will then read the VSWR at the design frequency. Alternatively, you can adjust the TUNE control until the minimum VSWR is found. This frequency is the actual, versus the desired, resonant frequency of the antenna.

An even more sophisticated version of this type of instrument is the MFJ-259 device (not shown). The front panel of the MFJ-259 has two meters: SWR and RESISTANCE. The SWR meter is calibrated up to 3:1, with a little uncalibrated scale to indicate higher SWRs. The RESISTANCE meter is calibrated from 0 to 500 ohms, which is

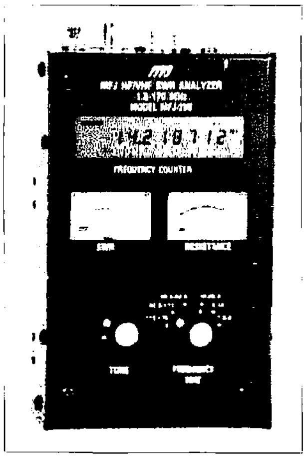

Photo B. MFJ-249 VSWR analyzer.

consistent with the SWR range. Two controls on the front panel are TUNE and FREQUENCY (MHZ) (a bandswitch). The MFJ-259 has a digital frequency meter to measure the operating frequency of the internal oscillator. This frequency counter can also be used to measure the frequency of external signal sources (*do not* connect the counter to the output of a transmitter—the instrument will be destroyed). The top end of the MFJ-259 has a number of controls and connectors. An SO-239 "UHF"-style coaxial connector is provided for the antenna connection. A BNC coaxial connector is provided to apply external signal to the frequency counter, while a push-button INPUT switch is available to switch the counter from internal to external signal sources. Another push-button switch is used to set the gate timing of the counter (a red LED on the front panel blinks every time the gate is triggered). The tuning is from 1.8 MHz to 174 MHz, while the counter will measure up to 200 MHz.

The MFJ-259 will work from an external 12 VDC source, or from an internal battery pack consisting of eight size-AA standard cells. MFJ recommends that either alkaline or rechargeable batteries, rather than ordinary zinc-carbon cells, be used in order to reduce the possibility of leakage that can damage the instrument (this is good practice in all battery powered instruments). I have a home-brew battery pack that uses eight size-D nickel cadmium batteries (4 Ah rating) that can be recharged from a 12 VDC power supply, and it works well with the MFJ-259.

Unlike many lesser SWR meters, this instrument is not fooled by antennas that have impedances consisting of both resistance and reactance elements. An example in the manual demonstrates an impedance of 25 + j25 ohms (i.e. R is 25 ohms and reactance, X, is also 25 ohms). When connected to a 50-ohm load one might be tempted to think the VSWR is 1:1, and some cheaper meters will so indicate. But the actual SWR is 2.6:1, which is what the MFJ-259 will read.

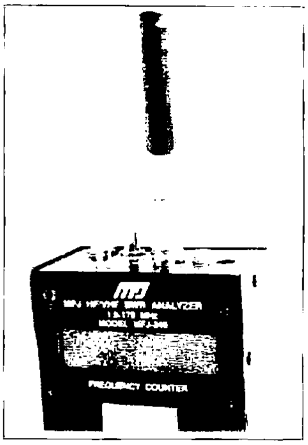

***Photo C.** MFJ-249 with dip meter adapter.*

The resistance measurement assumes a resistive load (the measurement is made at the antenna's resonant frequency), and is referenced to 50 ohms. The VSWR and resistance measurements should be consistent with each other. If the VSWR is 2:1, then the resistance should be either 100 ohms (100/50 = 2:1) or 25 ohms (50/25 = 2:1). If the resistance is not consistent with the VSWR reading, then you should assume that the impedance has a significant reactive component and take steps to tune it out.

In addition to antenna measurements, the MFJ-259 is equipped to measure a wide variety of other things as well. It will measure the velocity factor of transmission line, help in tuning or adjusting matching stubs or matching networks, and measure capacitance or inductance and the resonant frequency of L-C networks.

Photo C shows an MFJ-249 equipped with the MFJ-66 dip meter adapter. It can be used to make the MFJ-249 or MFJ-259 work in the same manner as a dip meter. Using this adapter allows you to measure the resonant frequency of tank circuits using the dipper approach, as well as to measure things such as the coefficient of coupling between two L-C circuits, transformers and other radio circuits.

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

I'd like to thank all the contributors who've made the first year of "Ham to Ham" possible, and as we embark on the second year of the column. I invite all readers to keep sending in their favorite tips, ideas, suggestions, and shortcuts. Without your input, we couldn't continue to achieve our goal: many ideas passed on from many hams to many other hams, not just my own soliloquies. Having said that, however, here is one of my own "inventions" that I thought you might like to hear about, but you needn't stop there. Feel free to go ahead and make one for yourself.

Just the right tool!

It's often been said that having the right tool for the job is half the battle. It's also true that a good assortment of tools is something that every ham and electronics hobbyist needs to enjoy the pastime to its fullest. Even today, when most of us buy many things ready-made, there are still those times when we have to build those little extras that no one else seems to offer.

I've built any number of these electronic accessories over the past 40 years in the hobby, but this tip isn't about building an electronic circuit (not exactly): rather, it's about making a tool that will help you build electronic projects.

I know you're thinking, "make my own tools ... no thanks!" Well, I'm not usually the type to consider making my own tools, either—that's definitely not my primary interest in electronics—but this tool is different. Follow along and you'll see why. Plus, it's not all that difficult to fabricate—otherwise I certainly wouldn't have been able to do it! I've never seen one like it offered by any of the manufacturers who normally supply tools to the electronics hobbyists market so, as such, it qualifies for my own personal test of build-or-buy, which is: "If it's already made, I'm probably better off just buying it, but if it's not, then perhaps I should consider making one myself!"

Like most hams, I find myself using lots of the 1/8" (3.2 mm) miniature and 3/32" (2.4 mm) subminiature phone jacks on all sorts of different projects. These are the common panel-mount variety of small phone jacks sold by Radio Shack™ and others for bringing audio—and any number of other signals—into and out of a piece of equipment.

They're great: they're inexpensive, they do the job, and they're easy to wire. The problem I've always run into, however, is in how to tighten down those tiny slotted nuts that are used on these jacks, so that they aren't ruined functionally or in regard to appearance. Sound familiar? Most of us simply end up using a pair of ordinary pliers, or perhaps a very small straight-blade screwdriver, in an awkward attempt to tighten down the tiny mounting nuts on these little jacks. I almost always ended up marring the slotted nut itself, or the panel behind it, or both! I've done a pretty good number on some of these over the years ... but not anymore!

I've found it best to sit back and try to imagine what the perfect tool for the job would be.

That approach usually works, and when thinking about this one, I came up with what I call the Slotted-Nut Tightening Tool. It's shown in **Fig. 1** and **Photo A**.

Here's what I had pictured: The slotted nuts used on these jacks would require a tool of the correct diameter, with the correct size of mating pins (or projections) built into its end. It would have to be made of a material that's harder than the material that the nuts themselves are made of, and it should be reasonably easy to grip. With these parameters in mind, I began to develop the two tools shown.

Oh, that's right, you'll actually need two tools—one for 1/8" jacks, another for the 3/32" variety—but the 1/8" one is probably most often used, so we'll start with it (the 1/8" tool can also be used on some miniature toggle switches that use the same type slotted-nut mounting). Most of the information supplied here will apply to the smaller diameter 3/32" tool as well.

The slotted nuts used on the miniature panel jacks appear to be made of a nickel-plated brass. The first prototype tool that I made for myself was also brass, but I wouldn't recommend using a material that soft for the finished tool because it's too easily damaged—that particular one was strictly a prototype. Once I had proven to myself that the tool dimensions were correct, Bud Hollibaugh, a friend who's also an accomplished machinist, made several more for me out of steel. These have proven to be very serviceable. Tool-hardened steel isn't really necessary; just garden variety steel is fine, since those slotted nuts you'll be using it on aren't made of a very hard material.

Following the dimensions shown in **Fig. 1**, the steel rod should be about 5" long for an easy grip and good control. It's made of 5/16" (.3125") diameter steel rod with a 5/8" long 7/32" (.221") hole drilled directly in the center: this can be the tricky part. If you can locate a section of hollow steel tubing with these dimensions instead—such as steel fuel line tubing—it will make the job much easier for the average home constructor. Solid rod perhaps has a little bit better "feel" to it, since it's heavier, but tubing will work just as well.

Filing or grinding down one end of the tubing, so that two "male projections" remain, is the only other critical part. Take your time. Following the dimensions in **Fig. 1**, with the tool clamped tightly in a bench vise, you should have little trouble matching up the projections on the new tool with the slots on an 1/8" panel-jack nut.

That, of course, is the final determining factor: to make the tool mate as closely as possible with a representative sample slotted nut.

The remainder of the tool's "handle" can be covered with rubber tape, heat-shrink tubing, appropriately-sized cable jacket, or whatever you might have, to add some "grip" and "cushion" to it. If you have or know someone who has a lathe, a knurled handle gives it a professional touch.

In everyday use, the slotted nut is started onto the jack with your fingers, as you've no doubt always done, and only the final tightening, for installation or for initial loosening for removal, is accomplished with your new tool. It works like a charm, and like so many things, you'll wonder how you did without it for so long!

A variation, in the interest of simplicity, was to take a fairly wide, flat-blade screwdriver and simply notch out the material from the center of the blade, leaving two projections that fit over the slots of the slotted nut. It works, but doesn't seem to work as well as the tool described in the main body of the article—it can slip off too easily and damage the nut or the panel.

In my own experience, I've found that using the suggested configuration shown in **Fig. 1** works best, and then one tool for each individual size of phone jack: one for 1/8" and another for 3/32" jacks.

This is the sort of item that you'll probably only ever need one of (for each size), and it should last nearly forever if it's made as shown. You'll thank yourself over and over again in the future for spending the small amount of time needed to make one of each of these now.

I must reserve the copyrights on multiple quantities of the tools shown here and for their commercial manufacture and marketing,

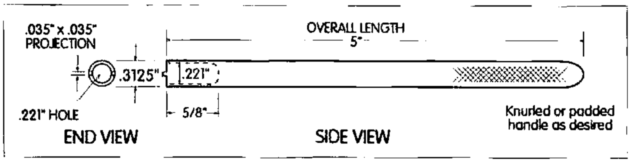

Fig. 1. End and side mechanical views of the Slotted-Nut-Tool© used for 1/8" miniature panel phone jacks. For the 3/32" Slotted-Nut-Tool, the hole (shown as .221") is bored to .144".

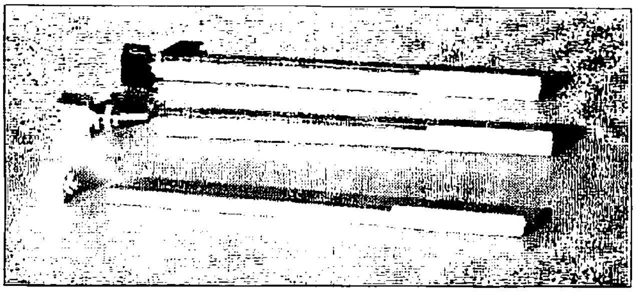

Photo A. From top to bottom: the 1/8" tool with phone jack nut; a 1/8" tool with an SPDT toggle switch nut; and a 3/32" with a subminiature phone jack nut.

but readers of this column should feel free to duplicate individual pieces for their own personal use.

Measuring upl

Speaking of tools, here's one from Peter Bergman NØBLX of Brainerd, Minnesota: "The US has been very slow to accept the metric system, yet in ham radio circles we use metric terminology daily. For measuring wire antenna lengths and coax cable multiples, I often thought that it would be nice to have a tape measure that read out in both metric and English graduations. I found one, from Stanley Tools of New Britain, CT. I have one of their No. 30-575 (7.5-meter/25-foot) steel tapes, and have my eye on their No. 34-827 PVC coated Fiberglas™ 30-meter/100-foot jobs. Santa, take note!

"Most 'super home centers' don't seem to carry metric tapes, but if several radio club members can get together on a single order, you might try one of the smaller, family-owned hardware stores to see if they can special-order some of the Stanley tapes, or the metric replacement blades, that are shown in Stanley's catalog. Your next antenna project could go much more quickly, when you're confident that everything has been measured correctly."

Moderator's note: I have an inexpensive 25-foot locking power tape made by Trophy (their No. 21925/T) that has continuous markings in centimeters, as well as in feet and inches, and Peter is right, it does make measuring for ham radio related cuts a good deal easier.

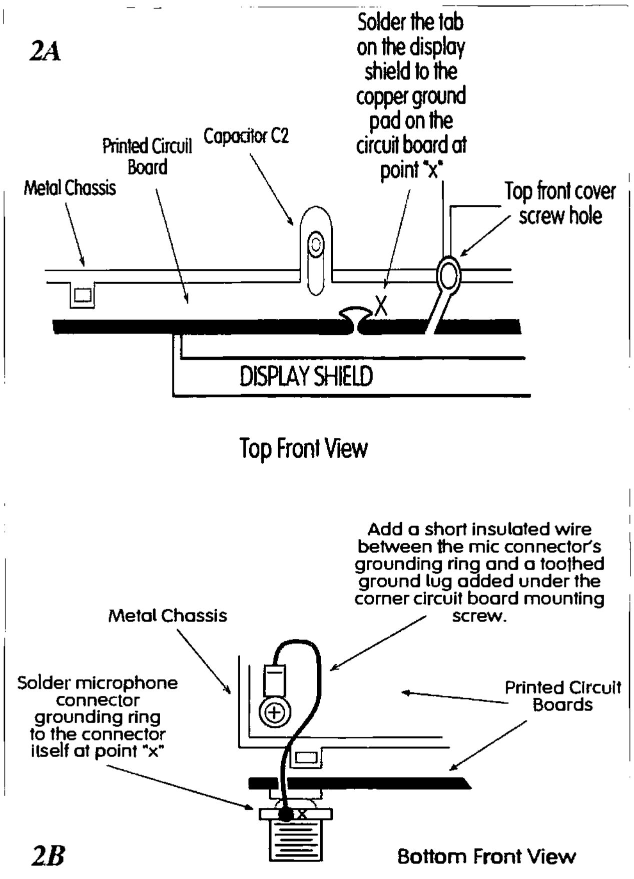
Well grounded ... continued

Last month, I talked about improving the RF grounding properties of ham equipment enclosures and covers, and I referred to the Alinco DR-1200T as an example. I picked it (as opposed to picked *on* it) because I own a couple of them, and have had the opportunity to work on a couple of small problems I've run into. I noticed that in the wintertime in Illinois, when the air is very dry, the high-voltage static buildup that can be generated by sliding across an automobile's synthetic seat cover can cause the DR-1200T to "reset" its memories when the mike connector is touched. Fortunately, it didn't do any more damage!

When I examined the mike connector grounding technique inside the radio, I felt that it might be improved by taking a couple additional steps. Those steps are shown in **Figs. 2A** and **2B**.

First, place a dab of solder on the display shield tab, looking at the radio's top, on the control printed circuit board, rather than depending upon mechanical grounding connections only (see **Fig. 2A**). Don't overdo this step; you may need to remove the shield sometime in the future, and it's not a good idea to go overboard!

Next, from the bottom of the radio, solder the microphone connector grounding ring to the shell of the microphone connector itself. The nickel plating on the connector should be scraped off at the point of soldering, and a small amount of solder paste used, to ensure a good alloy bond. Also shown in **Fig. 2B** is an added short-insulated wire from the microphone connector grounding tab directly to the circuit board's corner (ground) mounting screw, via a toothed soldering lug. This eliminates any ground impedance



Figs. 2A & 2B. *Alinco DR-1200T anti-static modification.*

in the traces on the control PC board, and permits any static discharge to take the shortest possible path to chassis ground.

These two easy modifications should help to protect your DR-1200T's "innards" from unexpected zaps from the outside; at least they did on mine.

The great equalizer

From William Thim N1QVQ: "If you find an inexpensive audio equalizer at a garage sale, flea market or hamfest, latch onto it and try inserting it between your transceiver's audio output jack and an external speaker. It can make a world of difference in improving the intelligibility of many signals you'll run across on the ham and shortwave bands.

"Since the human voice centers around the 1,000 Hz mark, bring that control up first, then adjust the other equalizing bands for the best clarity of overall sound. You can often eliminate much of the noise or other disturbing background, while accentuating the intelligibility of the speech range. The more bands the unit has, the better. It won't replace a good DSP for noise and heterodyne reduction, but it can make a difference on a minimum budget."

Moderator's note: If you do have a DSP, try an audio equalizer after it (as I have) and you'll probably find that it enhances the DSP's audio as well. Often, too, a second speaker located in another part of the room will make some signals "pop out of the mud" better than a single speaker. Varying room acoustics, and your own hearing "curve," make experimenting with various speakers and equalizer settings an inexpensive, intriguing continuing project.

Warm up your rotor

From Richard Mollentine WAØKKC: "An antenna rotor may bog down due to the grease on the gearing stiffening up with low temperatures. We cold-weather hams often have to wait for warmer, sunny days to coax our rotors into turning again! Working that weak DX station off the back of the beam isn't necessary anymore if you install a magnetic automobile engine-block heater on the bottom gearcase of your rotor's housing now, during nice weather.

"The unit that I'm referring to is sold at many auto parts stores or via the popular JC Whitney/Warshawsky catalog and is in the $18-$25 range. It has a powerful permanent magnet on its base and a length of 120 volt AC cord for powering the heating element from a standard wall outlet. Simply stick it to the bottom portion of your rotor's casing and run the AC cord to a switched outlet. It will heat up your rotor's gearbox to a 'toasty' temperature in only 20 to 30 minutes ... just don't forget and leave it on when the outside temperatures rise much above freezing!"

Moderator's note: Nice idea, Richard. In my own case, the housing on my antenna rotor is a non-ferrous casting, so a magnet-mount won't work, in and of itself. It could, however, be strapped to the rotor's base using an aluminum strap or two, or roof-eave and gutter exterior heat tape can be neatly wound around the rotor's base to warm up the rotor's gearbox in sub-freezing temperatures. You may have to experiment a bit with the idea to get it just right. Remember, however, don't get too close to the rotating top portion of the rotor housing or allow the rotating portion to rub against the heat tape, the engine block heater, or its AC cord. Be careful to follow all proper out-of-doors electrical practices if you need to extend the heater's AC cord or when plugging the heater into an exterior outlet. A ground-fault interrupter outlet may be required by your local codes; please don't try to do without it. Even if the GFI tends to trip when you're on the air, your rotor's gears will probably be warm enough to turn easily for that particular ham radio session.

S-meter readings exposed

From Klaus Spies WB9YBM: "The following S-meter value table shows the correlation between actual signal strength in microvolts at the antenna terminals of a properly calibrated receiver vs. the S-unit reading on that receiver. Note that there is an older 'ham' standard, and a newer 'world' standard. Both values are shown in **Table 1**.

"Some of this information was heard on the 'Voice of Japan' in March of 1994, the rest was calculated from their 6 dB per S-unit specifications."

Moderator's note: Each S-unit is 6 dB more as you go up the scale from S1 to S9. 6 dB represents a doubling of the voltage, but it takes four times the power to do that. To go up two S-units, the transmitting station would have to increase its power from 100 watts to 1600 watts, or 100 watts over the legal limit! That, of course, is assuming that the receiver's S-meter is right on the money. That's why it's difficult to put too much credence on some of the reports received over the ham bands. This is another of Klaus' handy tables that you might want to clip and paste somewhere over your workbench or at your operating position.

The importance of self-control

From Peter Albright AA2AD: "The primary purpose of a voltage regulator in a power supply, whether it's in an external, separate supply or in the ham

"S" Units	Old "Ham" Standard	Newer "World" Standard
S9	50.00uV	40.00uV
S8	25.06uV	20.04uV
S7	12.56uV	10.04uV
S6	6.29uV	5.03uV
S5	3.15uV	2.52uV
S4	1.58uV	1.26uV
S3	.79uV	.63uV
S2	.39uV	.31uV
S1	.19uV	.15uV

Table 1. *Two current standards of S-meter readings relative to microvolts of input signal to the receiver.*

Photo B. Chuck Wilson N6MUJ's "Sticky 2M Antenna" on the inside of his car's rear window.

transceiver/receiver itself, is to provide a source of stable, consistent voltage, either for reference or for powering the circuitry directly. Some circuits function quite well without power supply regulation and can afford to take power directly from the output of a power supply's output filter network, while others demand a more stable voltage or current for proper operation. It's always best to assume that the equipment designer knew which his equipment needed, and take any necessary measures to correct regulation problems that may develop, as soon as they're noticed.

"There are several symptoms that can indicate a faulty or defective power supply regulation circuit. If a short exists in the regulator, the fuse will generally blow, even though other sections of the power supply circuitry may be functioning normally—some devices use a so-called 'crowbar circuit' to blow the fuse deliberately in the event of an overvoltage condition. More commonly, however, voltage regulators tend to open, failing to supply their regulated output; only rarely, in very basic regulator circuits, do they supply full, unregulated output voltage (which is fortunate, since some circuits wouldn't tolerate the full unregulated output without developing additional problems). For that reason, don't be tempted to bypass a failed regulator unless you're absolutely sure of what you're doing.

"Here, then, are the common regulator configurations that might be found in ham power supplies and within the destination equipment itself:

"The simplest regulator is a zener diode—in series with a current-limiting resistor—from the power supply's output line to ground. Zener diodes begin to conduct at a set voltage, so that any excess voltage will be shunted to ground across the current-limiting resistor, and the diode itself, by brute force. Simple shunt zener regulators like this are for low-current demand applications only, and they provide no overvoltage protection in the event of a failure of the diode or its limiting resistor.

"To enhance the current-carrying capacity of the simple zener regulator, it's common to use the diode as part of the base circuit of a higher-powered 'pass' transistor, with the primary current flow between the emitter and collector of that transistor, and the zener acting strictly as a low-current control element in the transistor's base. 'Pass' transistors are generally mounted on a heat sink for greater heat dissipation capabilities and can be paralleled, with appropriate equalizing resistors, for even greater current-handling ability.

"Voltage regulators are available in handy-to-use integrated circuit packages, ranging from the simple three-terminal packages, available in both fixed and variable voltage outputs, that we've all seen (and perhaps used), to multi-pin programmable ICs. A fully automatic battery charger with voltage sensing capabilities would be one example of the latter (like the one that I recently built for my own needs).

"Just in case you're into 'older' wireless, I should briefly mention the 0A2 and 0B2 series of gas tube voltage regulators that might be found in some of these sets. They function in a similar manner to the simple zener shunt regulator circuit mentioned first, and are also strictly low-current regulators. The pleasant pink-blue color is unmistakable in the back of a tube-type rig, when 'real' radios had to glow to be working!"

Moderator's note: Peter does a nice job (as always) of explaining the basic voltage regulators to be found in today's ham power supplies. It's safest to disconnect the circuitry that's being fed the output of the supply when repairing and initially testing the defective voltage regulator circuit. The regulator, if it's doing its job, should put out very close to its correct voltage with or without a load on it, and if it isn't, at least you might prevent further damage to the secondary circuitry. Also, as Peter mentioned, the present-day line of IC regulators is generally very handy, but be sure to follow the recommended input/output capacitor bypassing, along with any other special considerations, as stated by the manufacturer of the device. Regulator "chips" can oscillate under certain conditions, and in addition to not doing their job properly, can be a tough problem to troubleshoot.

A sticky antenna idea!

From Chuck Wilson N6MUJ: "My 1995 Volvo wagon came from the dealer with an antenna for the AM/FM radio stuck to the inside of one of the rear windows. In an attempt to maintain the no-outside-antenna appearance of the vehicle, I decided to try the same approach for a 2 meter antenna on the opposite inside rear window. I used two 19-inch lengths of 1/2"-wide adhesive-backed copper ribbon, formed in a V shape, opened at the bottom of the V, and fed with 50 ohm coaxial cable, as shown in **Photo B.** and **Fig. 3.** I was able to easily access the repeater some 15 miles away from inside my garage, with just my HT and my new V antenna inside the car.

"I later replaced the 2 meter HT with a dual-bander, and the same antenna works well over the same distance on 440 MHz. I'm not sure what the SWR is—and I'm not sure that I want to know—but I do know that it works and that's really the bottom line, especially when I found that I could hit the same repeater from 40 miles away and from behind the hills that block its 'radio view.' It's an idea you might want to try if the XYL says 'negative' to an outside antenna on the new family buggy!"

Moderator's note: The self-stick copper foil that Chuck mentioned is often available from craft supply stores that cater to stained-glass makers. The foil is used to hold the glass pattern together during assembly. It comes in several different widths and roll lengths. The advantage of using copper vs. aluminum-foil tape is in copper's ease of soldering and greater tensile strength.

If you have trouble locating it, Radio Shack sells 3/8" wide self-adhesive window "alarm" foil (cat. #49-502) and self-adhesive

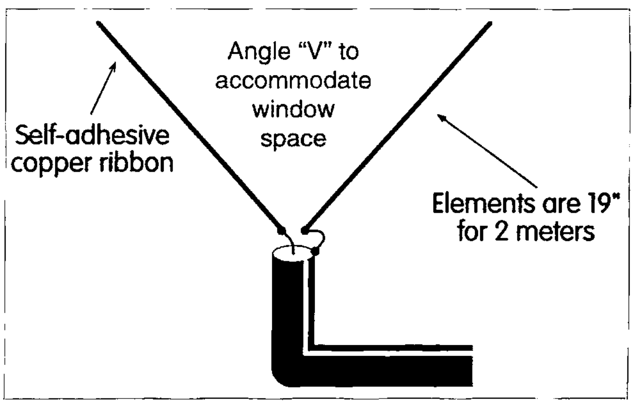


Fig. 3. N6MUJ's "Sticky Antenna."

foil connectors (cat. #49-504), that might be worth trying. By the way, 440 MHz is the third harmonic of 146 MHz, but a separate V for the 440 band, with about 6 3/4" of conductive tape in each leg, would most likely give even better results on that band. I would also only use low power—under 5 watts—into an antenna of this nature, both from an RF-in-the-car standpoint and from the standpoint of possible mismatch stress on the radio itself. I wonder how much the SWR would change with rain, ice, or snow on the windows?

VHF harmonic bug spray

From Richard Measures AG6K: "Here's the solution to a problem that's often caused by VHF harmonic energy leaking out via the external cabling from your transceiver. If you experience TVI from your amateur transceiver, even while transmitting into a well-shielded 50 ohm dummy load, this may well work for you. Try adding one or two VHF attenuator ferrite beads over each of the two active wires (hot and neutral) that make up the 120 volt AC line input.

"Just in case you haven't used ferrite beads before, they do not have to be in metal-to-metal contact with the wire that they're filtering to be effective, and in the case of the AC line cord, they definitely should not be. These ferrite products work by 'choking' the RF energy that's attempting to pass through the wire, and need only be around the wire's insulated outer covering to function correctly. The beads are generally rod-shaped, with a center hole large enough to pass the insulated wire completely through the bead's core, so the insulated AC wire is simply separated and strung through the bead.

"It may also be helpful to add a 470 pF, 1 kV disc-ceramic bypass capacitor from the AC line side of each bead to ground. Replace any two-wire AC line cord with a three-wire grounding cord, connecting the 'green' or ground terminal of the new cord to the transceiver's chassis ground. This provides a low-impedance ground-return path for both the unwanted harmonic energy and the small 60 Hz AC current that flows through the bypass caps. If any exposed 120 volt AC connections exist within the radio when implementing this cure, be absolutely sure that they are contained within an insulated, well-marked covering of some sort."

Moderator's note: Ferrite beads and choke cores are available from Radio Shack retail stores nationwide (#273-104 and #273-105), All Electronics (Tel: 1-800-826-5432), Amidon Associates (Tel: 714-850-4660), Palomar Engineers (Tel: 619-747-3343), as well as from other sources. 1 kV disc caps are obtainable from All Electronics and from Digi-Key Corp. (Tel: 1-800-344-4539). All Electronics and Digi-Key also carry a number of pre-made, packaged RF line filters at a slightly higher cost than doing-it-yourself, but they're often much easier and safer to use. Sometimes, simply wrapping a few turns of the AC line cord through a ferrite toroid core of sufficient diameter is all that's needed to quench VHF harmonics emanating from an amateur transceiver; try that as well. Other input/output cables to your transceiver might also benefit from being passed through a ferrite choke or core to suppress both in-band and out-of-band energy. It's very often a try-it-and-see situation.

And this ends another month of "Ham To Ham." Thanks to all who've submitted their tips, ideas, suggestions, and operating shortcuts—you're the ones who make the column work. Let's hear from more of you ... the more input I have, the better the results, and the more we can expand the column's scope in the future. Send whatever you would like to pass on to the address above; sending them to *73*'s offices in Peterborough directly only delays their use here.

As always, many thanks to this month's contributors:

NEVER SAY DIE

Continued from page 53

And now I've run across another approach that looks just about surefire, and doesn't depend on your almost totally unused determination. Look for a paperback by Dr. Arthur Coca, *The Pulse Test*. Spend the lousy five bucks. With this little book you'll learn how simple it is to find out what you're allergic to just by taking your pulse. And when you avoid allergens your fat melts away, as does arthritis. It's ISBN 0-312-95699-1, published by St. Martin's Press.

I don't know how much of the stuff in my bulging health literature file really works, but I'll keep reading and talking with people in the field I trust so I can report to you on what looks most promising.

Coca claims that when you stop dosing your system with things you're allergic to, it can stop tobacco and alcohol addiction. Look, you already know that no two people are exactly the same, so it shouldn't be a news flash that we all have different allergies. Most of mine got triggered by childhood immunization shots, so I've had a life of hay fever and asthma from dogs and cats. Eating watermelon stops my vocal cords from working and sure raises my pulse.

All you have to do is measure your pulse several times a day. Mine rests at 60 per minute. Then you eat, drink, or breathe something and measure your pulse 30 and 60 minutes later and see how much it goes up. If it does, you've found something you should avoid. Well, read the book, which was first published 40 years ago.

Déjà Vu

There's a remarkable parallel between the beginning months of the personal computer and cold fusion. It's almost enough to encourage anyone with spunk to head for the cellar or garage and start experimenting.

Since I was there from day one of the microcomputer revolution and, maybe helped it to get started with my magazines and proselytizing, I know how it was.

When the MITS Altair 8800, the first microcomputer, was introduced to the market back in January 1975, the computer professionals looked at it and ridiculed it as a toy, and not worth even thinking about. This attitude was fanned by *Computerworld*, the main publication in the computer field. It made fun of microcomputers, doing its best to put them down as of no interest or value to true computer professionals. It's my belief that this publication was largely responsible for the destruction of virtually all minicomputer companies, eventually putting tens of thousands of people out of work. It helped companies like Wang, DEC, Prime, Data General, and hundreds of smaller firms miss the

HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92837

Foxhunt day, step by step

Is your foxhunt scheduled yet? Last month's "Homing In" led you through the process of planning and promoting an international-rules radio direction finding (RDF) contest. Foxhunts are a mainstream ham activity in Europe and Asia, but they won't gain a toehold here until more ham clubs and conventions get busy and sponsor them. It's great fun, and it might start a new tradition for your club's hamfests.

August's column covered advance work, including site selection, transmitting gear, promotion, education, and registration. My recommendations are based on experiences of the Southern California Six Meter Club (SC6MC), which sponsored foxhunts at the ARRL Southwestern Division convention (Hamcon-95) and the West Coast VHF/UHF Conference (VHF-96). This month, we'll cover what happens on hunt day.

Special punches

Fox transmitters are concealed and unattended. Therefore, judges need a method of proving that the hunters find each fox. World Championship foxhunts employ a "punch" method, established by orienteers, that we've adopted (see **Photo A**). Orienteers verify that competitors visit the required checkpoints by having a special punch at each point. Each punch has a distinctive pattern with up to nine pins. Competitors carry a card with numbered spaces for punching. Cards and punches can be bought by mail from outfitters such as J. Berman Orienteering Supply, Post Office Box 460, Sunderland MA 01375; (413) 665-7822. Twenty different punches are available; purchase as many as you need for less than three dollars each. Berman also sells Silva orienteering cards by the hundred.

Ukrainian hunts feature special machines at each fox that timestamp the cards, much like punching a time clock. This would be important if rules demanded that the foxes be located in a particular order, but such is not usually the case. However, it is mandatory that hunters punch numbered spaces on the card correctly. The punch at fox #1 must be used to mark square #1 on the card, and so forth. Be sure to announce this requirement before the hunt; it was a source of contention at VHF-96. Some hunters were unaware of the rule and marked square #1 with whichever punch they found first, etc.

I like the special punches, but you don't have to use them. For practice hunts before I got the punches, I made up slips of paper with fox numbers printed on them to give to the hunters at the start. I put a different colored pen or pencil at each fox, which they used to circle the appropriate numbers.

It takes a team of volunteers to put on a well-run foxhunt. You will need timers at the starting line to send off the hunters at exact intervals, plus helpers at the finish line to collect the cards and mark finishing time on them. Things can get hectic at these two locations, so two persons are better than one. Remember, these positions do not require licensed hams.

Fig. 1. A sample spreadsheet sorted by age. I'm sure our contestants don't want their birthdays listed in a widely-read magazine, so these are some made-up names.

Have Course Marshals scattered in the woods to watch over the activities. Contestants know they should not help one another in any way or vandalize the foxes, but having Marshals helps prevent temptation. Marshals should also be on the lookout for any health problems that might develop during the hunt. Don't station them near foxes—that would be a giveaway. Have them keep moving along. Encourage them to carry cameras to document the fun for your club's newsletter or Web page. They can also serve as judges to check over the results before prizes are awarded.

The Region 1 ARDF Working Group requires starting corridors between 50 and 250 meters long at championship events. Competitors run into the corridor when instructed by the start timers. When they reach the end, they may turn on their RDF gear and take off into the forest. The end of the corridor should not be visible from the start point.

One purpose of a corridor is to prevent those waiting at the starting line from seeing which way hunters go. This is particularly important if the start point is in the middle of the venue. Rather than try to put up curtains or fences, try to find a natural corridor at your site. At VHF-96, we put the start point at the northwest corner of the park. Starters went over a small footbridge, up a hill, and disappeared into the woods—an ideal starting situation. At the Hamcon-95 hunt, we used a 50-yard walkway between two buildings.

Depending on your site, the finish line can be next to the start or at another location where family members can wait (and perhaps picnic). Mark the end point clearly on the course map. At international meets in very large forests, a transmitter on a separate frequency beacons regularly from the finish area. At our hunts, the finish line beacon frequency doubled as an emergency calling frequency, monitored by the finish line attendant. Hunters were forbidden to transmit on the hunt frequency. Note that competitors are not required to locate the exact placement of the finish line transmitter; no punch should be placed there.

Photo A. J. Scott Bovitz N6MI attaches an orange orienteering punch to a well-concealed fox transmitter at VHF-96.

International Amateur Radio Union (IARU) rules call for an ending corridor of 50 to 100 meters leading up to the finish line. I think an ending corridor is unnecessary, but you may want to have one if there are some elite runners and you're worried about a "photo finish." In any case, be sure your finish line or corridor is well marked.

Bring your laptop

While you might prefer to announce age divisions in advance, we decided to wait until all registration was done. Then we chose division breakpoints and individual start times to even up the field. Upon registering, each hunter gave his/her name, callsign, date of birth (DOB), and team affiliation, all of which went into the computer.

Although I don't know of any software dedicated to foxhunt or orienteering competitions, I found that a spreadsheet program with date/time and sort capabilities works just fine. I chose Microsoft Excel for Hamcon-95 and VHF-96. After registration was complete and all hunters were entered, one person per line, I sorted and printed the data by name. This printout would be posted at the site and each hunter would be asked to verify that his/her data was correct.

Next, I sorted and printed a listing by age (**Fig. 1**). The committee used this sort to select age division breakpoints. The goal was to be fair from an abilities point of view, but also to avoid any division having many more competitors than the others, which would unduly extend the starting process. For both hunts, our divisions were Youth (17 and under), Prime (18 through 30), Masters (31 through 45), and

Fig. 2. First part of the start sequence spreadsheet, sorted by time. One competitor in each division starts in each wave. Age and DOB columns have been hidden.

Seniors (46 and over). To the spreadsheet, I added Division, Wave, and Start Time columns and entered the division designations when they had been decided upon.

Now it was time to determine the starting order. One to four hunters would start at a time, always from different divisions. The number of start times (waves) equals the number of competitors in the category having the greatest number.

Just as players are "seeded" in tennis tournaments, start times should be chosen with the anticipated abilities of the hunters in mind. Slowest hunters should start first, fastest last. This gets the event over sooner, so everyone can find out the results in a timely manner. Family members should not start at the same time; youth should go out early, parents later. This way, the kids are less likely to look for their parents on the course. We tried to separate family members and regular T-hunting partners by at least four waves on our hunts. We also avoided starting members of the same team in the same wave.

We chose three-minute starting intervals in the VHF conference hunt. With 11 waves and a two-hour time limit, the maximum event time would be two-and-a-half hours from first starter to disqualification time for the last starter. Since there were to be six foxes, half of the runners would start on fox #1 and half on fox #4. Some would say it is more fair to start at six-minute intervals (all on fox #1), but then the event could take three hours. We didn't want to finish that late.

Once the wave numbers and a dummy pre-start time were entered in the spreadsheet, Excel calculated the scheduled start times for each competitor. I then did a sort by wave number, which gave a starting time lineup to be announced before the hunt. The printout of scheduled start times (**Fig. 2**) has added columns for Start and Finish. The Start column is there in case something goes wrong and the actual starting times end up being different from the scheduled times. If they turn out to be the same, it's easy to insert them in this column with the Fill Across command.

Be sure to allow plenty of time to get the hunt organized. Don't start the hunt until a full cycle of fox transmissions has been heard, so you'll know that all are working properly. Our VHF-96 entrants were sent from the assembly point to the site at 1 p.m. Guessing the time required to make announcements and get underway, I printed up sheets with scheduled times starting at 2 p.m., 2:15, and 2:30. Because of problems with the foxes, we ended up starting at 2:49.

As hunters arrive at the site, have them put all their RDF gear in the impound area. (We used a big blue tarp on the ground.) They are not allowed to pick it up again until one minute before it is their turn to start, and may not turn it on until they reach the end of the start corridor. Gather everyone around for instructions, rules, and announcements (see **Photo B** and the sidebar).

I think it works best to have two people at the starting table. One watches the clock and officially starts the hunters, while the other calls the hunters by name in advance and makes sure they're on deck before their times. Be sure that clocks at the start and finish points are synchronized. IARU requires that less than one second difference between these clocks be verified, and insists that competitors be allowed to check their watches against the starting point clock.

As hunters cross the finish line, the attendant takes their punched cards, marks exact finish time, and number of foxes found on the cards, then gives the cards to the scorekeeper. The spreadsheet will do the subtraction to get elapsed times. Once all start/finish times are entered, it's easy to find the individual winners with one "sort" command (**Fig. 3**). The first sort key is division, the second is number of foxes (descending), and the third is elapsed time (ascending). With another sort, you can find team winners: The first key is team; the second and third are as before. Once the judges verify the numbers, it's time to award prizes and certificates (**Fig. 4**).

When is the next one?

Whew! It's over! Another successful foxhunt! You may find, as we did, that everyone is having so much fun they're not ready to go home yet, although all the activity has made them hungry. For our hunts, we arranged for a group discount at a nearby restaurant for a "Dutch treat" dinner, to prolong the good times and plan the next hunt.

If you would like to try the spreadsheet scoring method, I will provide my sample Excel tem-

Rules, Rules, Rules

Important starting point announcements and instructions:

- Location of restrooms.
- Boundaries and forbidden areas, if any.
- No assistance on the course.
- Do not transmit unless an emergency occurs.
- Punch the right square for each fox on the card.
- No visitors on the course.
- Start times for each runner.
- Put your name and start time on your card.
- A lost card means disqualification.
- Verify your name, team, and DOB on the printout.

***Photo B.** Your columnist gives final instructions before the first VHF-96 hunter leaves the start corridor. (Photo by J. Scott Bovitz N6MI)*

I presently spend lots of time handling via E-mail or snail-mail. Even if you don't have an RDF question, the site is worth visiting because you'll find updates to my T-hunt book and a complete "Homing In" index, listing topics for over 90 columns. URL http://members.aol.com/homingin/ should get your browser there.

Of course your mail, postal or electronic, is still welcome. Please note my new ZIP code atop this column. Send e-mail to: Homingin @aol.com or 75236.2165@ compuserve.com.

Ham Radio Fun

Communications Simplified, Part 9

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

As we mentioned last time, with more modulation, even more sidebands might be required to keep the amplitude constant. So we need to learn how to measure the amount of modulation. This can be done in two ways—using the deviation, or using a modulation index.

Deviation

Deviation measures how far the carrier swings from its center or unmodulated value. For example, commercial FM broadcast stations are allowed to deviate up to ±75 kHz from their center frequency. Thus a station on 96.3 MHz could swing its carrier down to 95.225 MHz (96.3 MHz minus 75 kHz) or up to 96.375 MHz. Police, fire, or ham FM radios, on the other hand, generally use ±5 kHz deviation.

Note how we said that commercial FM broadcast stations *are allowed* to deviate up to ±75 kHz. This is not a technical limit—it would be easy to build equipment which deviates a lot more. Rather, 75 kHz is a maximum limit imposed by the FCC to prevent interference with adjacent stations. Likewise, 5 kHz deviation is used by fire, police, ham, and other communications equipment to avoid interference with other users. So, unlike the case of AM where 100% modulation is a limit which you simply cannot exceed for technical reasons, the maximum amount of FM deviation is more of a "good neighbor" policy, usually enforced by the government.

Modulation index

The modulation index is the second way of measuring the amount of FM modulation. The modulation index (we will abbreviate it as *MI*, but there are several other symbols often used) is defined as:

$$MI = \frac{\text{deviation}}{\text{modulation frequency causing that deviation}}$$

For example, an FM station transmitting a 5 kHz audio signal (this is the modulation frequency) at a 15 kHz deviation would have a modulation index of 15/5, or 3.

You can see that, even if the deviation stays the same, the modulation index can vary all over the place. For example, if that FM station keeps the same 15 kHz deviation, but the audio frequency changes from 5 kHz to 50 Hz, the modulation index suddenly changes to 15,000 Hz divided by 50 Hz, or 300 (be careful to use the same units on both the top and bottom of the equation).

It's the modulation index that determines how many sidebands are needed to keep the amplitude of the FM signal constant. For example, if the modulation index is 0.2 or 0.3, then just one set of sidebands is needed; if the modulation index is 10, then 13 sidebands would be needed on each side of the carrier to keep the amplitude constant. The calculations to determine how many sidebands are needed at any given modulation index are fairly complex, and involve something called Bessel functions. To avoid all this work, most people use a table like Table 1, which

		Sideband												
MI	Carrier	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	11th	12th	13th
0.0	1.00													
0.25	0.98	0.12												
0.5	0.94	0.24	0.03											
1.0	0.77	0.44	0.11	0.02										
1.5	0.51	0.56	0.23	0.06	0.01									
2.0	0.22	0.58	0.35	0.13	0.03									
2.5	-0.05	0.50	0.45	0.22	0.07	0.02								
3.0	-0.26	0.34	0.49	0.31	0.13	0.04	0.01							
4.0	-0.41	-0.07	0.36	0.43	0.28	0.13	0.05	0.02						
5.0	-0.40	-0.33	0.05	0.36	0.39	0.26	0.13	0.05	0.02					
6.0	0.15	-0.28	-0.24	0.11	0.36	0.36	0.25	0.13	0.06	0.02				
7.0	0.30	0.00	-0.30	-0.17	0.16	0.35	0.34	0.23	0.13	0.06	0.02			
8.0	0.17	0.23	-0.11	-0.29	-0.10	0.19	0.34	0.32	0.22	0.13	0.06	0.03		
9.0	-0.09	0.24	0.14	-0.18	-0.27	-0.06	0.20	0.33	0.30	0.21	0.12	0.06	0.03	0.01
10.0	-0.25	0.04	0.25	0.06	-0.22	-0.23	-0.01	0.22	0.31	0.29	0.20	0.12	0.06	0.03

Table 1. Carrier and sideband amplitudes (from Bessel functions).

actually provides more information than just the number of sidebands.

Let's look at an example. Let's assume we have an FM broadcast station which transmits a 4 kHz tone at a deviation of 2 kHz, giving us a modulation index of 0.5. For this modulation index, **Table 1** gives us the following information: MI = 0.5; Carrier = 0.94; 1st sideband = 0.24; and 2nd sideband = 0.03.

This tells us that there are two sets of sidebands on each side of the carrier: The carrier amplitude is 94% (0.94) of the unmodulated value, the first set of sidebands has an amplitude of 24% (0.24) of the unmodulated carrier, and the second set of sidebands has an amplitude of 3% (0.03) of the unmodulated carrier.

Notice that the carrier is now smaller than it would be if left unmodulated. Unlike in AM, where the carrier stays the same size no matter what the sidebands do, an FM carrier changes size as you modulate it. This makes sense when you realize that the total FM signal voltage and power (which consists of the carrier plus all the sidebands) has to stay the same all the time. When the sidebands appear, something else has to decrease to keep the total voltage and power the same.

Let's look at this in more detail. Suppose the original carrier (before modulation) was 10 volts rms, and was sent into 50 ohms. The total power would then be found from $P = V^2/R$ to be 2 watts.

Now let's see what happens with the modulation index of 0.5.

The carrier voltage is now 10 x 0.94 = 9.4 volts, and its power (still assuming a 50-ohm load) is: $9.4^2/50$ or 1.7672 watts, less than before.

The first sideband is 10 x .24 = 2.4 volts, and its power is: $2.4^2/50$, or .1152 watt. Remember, there are two of these sidebands (one upper and one lower), so their total power is twice that, or 0.2304 watt.

The second sideband is 10 x .03 = 0.3 volts, and its power is: $0.3^2/50$, or .0018 watt. Again, there are two of these sidebands, so their total power is twice that, or 0.0036 watt.

When we add all of these powers together, the 1.7672, 0.2304, and 0.0036 watt add to almost exactly 2 watts (the slight error is because **Table 1** gives the coefficients to only two decimal places.) So the modulated carrier has the same power as the unmodulated carrier.

	Voltage (volts)	Power Each (watts)	Total Power (watts)
Carrier	- 4	.3200	.3200
1st SB	0.7	.0098	.0196
2nd SB	3.6	.2592	.5184
3rd SB	4.3	.3698	.7396
4th SB	2.8	.1568	.3136
5th SB	1.3	.0338	.0676
6th SB	0.5	.0050	.0100
7th SB	0.2	.0008	.0016
Total power, carrier plus sidebands:			1.9904

Table 2. The sum of an FM carrier wave and its sidebands.

Let's try another example. Suppose the unmodulated carrier is again 10 volts, the load is still 50 ohms, the modulating frequency (which would be the audio in an FM broadcast station) is 1 kHz, and the deviation is 4 kHz, giving a modulation index of 4. **Table 1** tells us that the carrier has an amplitude of -0.40, and that there are seven sidebands, of which the first also has a negative amplitude. Since amplitudes can't be smaller than zero, what do the minus signs mean?

The negative amplitude here simply means that the phase has reversed, so the carrier and the first sideband both have opposite phases from what they were at lower values of the modulation index. As far as the power is concerned, this doesn't matter, so we can still add up the total powers as in **Table 2**.

Again, the total power is about 2 watts, with a slight error because the Bessel values are accurate to only two decimal places. So the total power of the FM signal doesn't change with modulation, although the power gets shifted around between the carrier and the sidebands.

Let's look at the negative numbers in **Table 1** one more time. At a modulation index of 2, the carrier had a value of 0.22, while at an index of 2.5, the carrier became -.05. Obviously, somewhere between 2 and 2.5, the carrier value went from plus, through zero, to minus. At the zero (which occurs when the modulation index is 2.405) the carrier completely disappears, and all the power is in the sidebands. This point is useful because it lets us calibrate a deviation meter—we observe the signal on a spectrum analyzer and increase the deviation until the carrier disappears. Of course, we have to be careful because the carrier also disappears at other values, such as at a modulation index of 5.5 and 8.65.

We can see this a bit better if we graph the data from **Table 1**, as shown in **Fig. 1**. Here you can see how the carrier starts out with a magnitude of 1 when the modulation index is 0, then decreases until, at a modulation index of 2.405, it crosses the zero line and becomes negative. It then reaches a negative maximum at a modulation index of about 4, and then goes up again. It keeps oscillating, but generally gets smaller and smaller, while more and more sidebands appear at the right.

Bandwidth

The more sidebands there are, the greater the bandwidth of the signal. At a very low modulation index (below 0.5), there is only one set of sidebands, which makes the total bandwidth about the same as AM. With larger modulation indexes, the number of sidebands increases and the bandwidth goes up.

Fortunately, something else is happening which keeps the total bandwidth reasonable. Remember how we defined the modulation index:

$$MI = \frac{\text{deviation}}{\text{modulation frequency causing that deviation}}$$

To get a large modulation index, you need a large deviation but a small modulation frequency. The modulation frequency, however, determines the

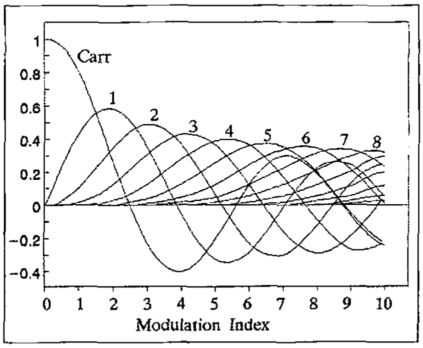

Fig. 1. FM carrier and sideband amplitudes.

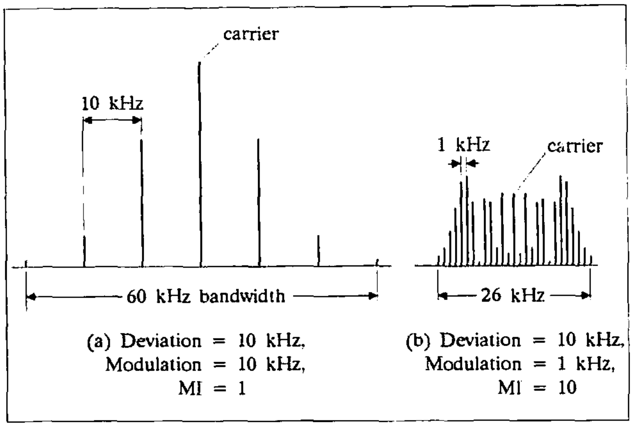

Fig. 2. FM, same deviation, different modulation index.

spacing between sidebands. So at a high modulation index, you may have many sidebands, but they will be close together, so the total occupied bandwidth will not be as large as you might think.

Fig. 2 shows an example. At left, we see the spectrum when the deviation is 10 kHz and the modulation frequency is also 10 kHz; the resulting modulation index is 1, and there are three sidebands on each side. Since they are 10 kHz apart, the total bandwidth is 60 kHz. On the right, the deviation is also 10 kHz but the modulation frequency is only 1 kHz. The modulation index is now 10 and there are 13 sidebands, but the sidebands are only 1 kHz apart, so the bandwidth is only 26 kHz.

In the real world, things are somewhat more complicated than what we've described so far. Our discussion so far has assumed that the FM transmitter is sending out pure tones—much like an announcer whistling a single note into the mike. In practice, regardless of whether we deal with voice, music, or data, the modulation signal consists of many different frequencies at the same time. The Bessel function analysis then becomes much more complicated, because the interactions between all these tones themselves produce additional sidebands.

Then too, even when the modulation is fairly simple, different frequencies exist at different voltages. In music or voice, for example, the high frequencies tend to be much weaker than the lows. Even though FM stations often boost the highs (this is called *pre-emphasis*) to overcome noise, the highs are still generally weaker than the lows, and so produce lower deviation. Commercial FM broadcast stations therefore carefully adjust their audio response to utilize their assigned spectrum as fully as possible.

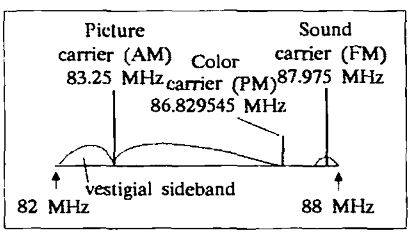

Fig. 3. TV channel 6 spectrum.

Channels

As we mentioned earlier, commercial FM stations are allowed to deviate up to ±75 kHz. Although the frequency response of their broadcast sound only extends to 15,000 Hz, they often transmit modulation up to almost 100 kHz (more on this later). The high-frequency material they may transmit up near 100 kHz is at a modulation index below 0.5 so it generates only one set of sidebands, but even this one single sideband set means their bandwidth may extend out to 100 kHz on each side of their center frequency. Hence, commercial FM broadcast stations are assigned a *channel* which is 200 kHz wide.

The U.S. FM broadcast band extends from 88 to 108 MHz; the lowest FM station on the band would be assigned a 200-kHz-wide channel from 88.0 to 88.2 MHz, with its center frequency at 88.1. The next station up could be centered at 88.3 MHz, with its channel extending from 88.2 to 88.4 MHz. This explains why all the FM stations in your area are at odd tenths of MHz: .1, .3, .5, .7, or .9 on the dial.

In practice, though, two stations in the same area cannot be assigned adjacent channels, because the bandwidth of the tuned circuits in FM radios is not narrow enough to separate two such adjacent stations. So rather than being spaced 200 kHz apart, FM stations in the same city are often 400 or even 600 kHz apart. The in-between channels are used by stations farther away.

TV channels are assigned in the same way. Each TV channel is 6 MHz wide. Starting at the low end, their frequencies are:

Channel 2: 54 to 60 MHz
Channel 3: 60 to 66 MHz
Channel 4: 66 to 72 MHz
Channel 5: 76 to 82 MHz
Channel 6: 82 to 88 MHz
Channel 7: 174 to 180 MHz, and so on.

Note several interesting things: There is no channel 1; channels are usually adjacent, but there is a 4 MHz break between channels 4 and 5; channel 6 is just under the FM band, which starts at 88 MHz; and there is a big break between the "low VHF" channels, channels 2 through 6, and the "high VHF" channels, numbered 7 through 13. The space between them contains the FM broadcast band, aircraft frequencies, the 2 meter amateur band, marine channels, and commercial two-way frequencies. The UHF channels begin at 470 MHz and extend up to 900 MHz.

In any given area, to avoid interference between them, two TV stations will never be assigned adjacent channels. In New York City, for example, there are TV stations on channels 2, 4, 5, 7, 9, 11, and 13. How can there be stations on both channels 4 and 5? Only because there is a 4-MHz-wide space between them—they are not really adjacent.

If you have cable TV, you may be wondering why there can be stations on adjacent cable channels. The reason is that most modern TV sets can (just barely!) separate two adjacent TV stations under the condition that they are both the same strength. The cable network has full control over the strength of all its channels, and can satisfy this condition. On-the-air signals, on the other hand, vary in strength depending on how far you are from the transmitter, and there can often be tremendous differences in signal strength between stations.

While we are discussing TV transmission, this might be a good place to again mention what kind of modulation is used for TV, and how the 6 MHz channel is divided up.

Fig. 3 shows a typical TV channel spectrum. We show channel 6, but all the VHF and UHF TV channels are laid out exactly the same way. Each TV channel takes exactly 6 MHz of bandwidth; channel 6 uses 82 to 88 MHz. The

picture is sent using AM vestigial sideband modulation (which was discussed at the end of Part 7), with the AM carrier exactly 1.25 MHz from the bottom frequency of the channel; in channel 6, this places it at 83.25 MHz.The sound is sent on an FM carrier, whose frequency is exactly 4.5 MHz above the picture carrier; this places it at 87.75 MHz. In fact, if you live in an area with a channel 6, and if you have an FM radio which will tune slightly below the 88 MHz end of the FM band, you can hear the channel 6 TV sound.

3.579545 MHz above the picture carrier (which is 86.829545 MHz in this case) is a third carrier, which carries the color or *chroma* information. Since this carrier is sent as part of the picture signal, it is called a *subcarrier*. This signal uses phase modulation.

Phase modulation

PM or *Phase Modulation* is so similar to frequency modulation that equipment designers often use a PM modulator to produce FM. Because of their similarity, it is difficult to clearly explain the difference between FM and PM, so read this section very carefully.

First, to make sure you fully understand FM, let's talk about a commercial FM broadcast station at 96.3 MHz. The frequency of its unmodulated FM carrier is its center frequency (96.3 MHz). When the audio signal starts, the frequency varies (deviates) from its center value. At any given instant of time, the frequency change at that instant is proportional to the audio voltage at that instant. For example, suppose the transmitter is designed to produce the full ±75 kHz deviation with an input voltage of ±7.5 volts. The signal frequency might then follow the structure of **Table 3**.

Whenever the audio voltage is +1 volt, the transmitter frequency at that instant will be 96.310 MHz. It doesn't matter how the audio voltage got there—the signal could be coming from a 1-volt DC battery, or it could be the peak of a 1-volt sine wave, or it could just be passing through the +1 volt value on its way up or down some strange-looking waveform. At any instant of time, the FM signal frequency depends only on the audio voltage at that same instant.

Another important concept to understand is that if the audio voltage remains constant for a while, then the signal frequency is also constant (though it may not be at the center frequency). When the audio signal changes, the signal frequency changes, and the faster the audio changes, the faster the signal frequency changes.

Now, let us discuss phase. Phase measurements are used to compare two or more signals to see if they are "in step" with each other, and if not, how much they differ. Let's consider a real simple-minded example, in which someone talks about a parade and says "that marcher is 180 degrees out of step with the others." What is meant is that this particular marcher is doing the exact opposite of everyone else—when everyone else steps forward on their left foot, this marcher steps with his right foot, and so on. Zero degrees phase difference means being in step; 180 degrees difference means doing the exact opposite; 90 degrees difference would mean being "halfway out of step," and so on.

Although phase measurements usually compare two or more signals with each other, we can also use them to compare one signal to itself. Let's return to that parade marcher. Suppose you see him (or her) take two steps; based on this, you can predict when the third step should come. If the marcher takes that third step a little sooner than you expected, then that step occurs earlier in phase. To do that, the steps are coming closer together, so the frequency has also increased. So phase changes go with frequency changes.

Hence, frequency modulating a signal produces phase modulation, and phase modulation produces frequency modulation. So what is the difference?

Remember the definition of modulation index:

$$MI = \frac{\text{deviation}}{\text{modulation frequency causing that deviation}}$$

The difference between FM and PM is this: Suppose an announcer steps up to the microphone and whistles a low note (for instance, 500 Hz), followed by a high note (for instance, 1000 Hz) at the same volume (imagine a sound like "boop-beep"). In both FM and PM, these two notes produce both frequency and phase modulation, but in FM the deviation for both notes would be the same (meaning that the modulation index is different), whereas in PM the modulation index is the same (meaning that the deviation is different).

In practice, things get a bit confused here, because radio stations routinely boost the treble to reduce the noise, so the deviation would change slightly even in FM, but let's ignore that little complication. So, for example, FM might produce 2000 Hz deviation for both notes; the modulation index would then be 2000/500, or 4 for the 500 Hz note, but only 2000/1000, or 2 for the 1000 Hz note.

In PM, on the other hand, the 500 Hz note might produce 1000 Hz deviation (for a modulation index of 1000/500, or 2), while the 1000 Hz note would produce 2000 Hz deviation (for a modulation index of 2000/1000, also equal to 2).

This greatly affects the bandwidth of the signal. In FM, lower frequencies produce a higher modulation index; this gives more sidebands, but they are closer together, so the total bandwidth stays pretty constant and doesn't depend on the audio frequency. In PM, on the other hand, the modulation index is independent of audio frequency, so the number of sidebands stays the same regardless of audio frequency, but with higher audio frequencies the sidebands are farther apart, so the bandwidth increases.

The bottom line is that PM is useful for communications-quality audio, whose audio content doesn't go much above 3000 Hz. It would not be good for real hi-fi audio, because the high frequencies in hi-fi audio would require too much bandwidth.

To finish up, here are two more points. First, you can generate FM with a PM transmitter, and vice versa. All you have to do is to process the audio going into the transmitter. For example, an FM transmitter produces too little deviation for high frequencies, so sending the

Audio Voltage (volts)	Frequency Change (kHz)	Signal Frequency (MHz)
+ 7.5	+ 75	96.375
+ 1.0	+ 10	96.310
0	0	96.300
- 7.5	- 75	96.225

Table 3. The signal frequency of a transmitter producing ±75 kHz deviation with ±7.5 volts input.

audio through a high-pass filter (which increases the high-frequency treble) will increase the deviation to that of a PM transmitter. Doing the opposite, cutting the treble with a low–pass filter, will make a PM transmitter send out frequency modulation. In fact, many FM transmitter designs do just that; it results in a more stable signal.

Finally, as we said earlier, things get a bit more complicated because of FM stations' efforts to reduce noise. Since most audio signals contain mostly mid-range signals and relatively little energy in the high frequencies, most commercial FM transmitters boost the treble; this process is called *pre-emphasis*. This makes the signal a bit more like PM, but it's okay because of the low amount of high frequencies to begin with. A *de-emphasis* circuit in the receiver then reduces the treble back to the normal level. In the process, the de-emphasis circuit also reduces any hiss which crept into the signal.

Conclusion

FM and PM are similar to each other, but fundamentally different from AM. All three have a carrier which is modulated in some way, and that modulation causes sidebands, but how those sidebands interact with the carrier is very different.

Because noise basically affects amplitude, you can remove it from an FM or PM signal by clipping (limiting) the signal to a fixed amplitude; this does not change the frequency or phase and so doesn't affect the modulation. However, you cannot remove this noise from an AM signal without affecting the amplitude, and therefore the modulation itself. FM and PM can therefore provide the better signal-to-noise ratio that listeners want for good music, but getting the best signal-to-noise ratio also requires a wide deviation. Hence, FM signals used for music also have fairly much wider bandwidth than most AM signals.

In those communications applications where real hi-fi sound is not required, narrow-band FM (NBFM) with fairly small deviation and a small modulation index can produce bandwidths not much larger than AM. This is the mode that is used for most mobile communications such as amateur repeaters, police and fire communications, business users, and cellular telephones. 73

Number 68 on your Feedback card

From Kilowatts To Femtowatts?

Wrestling with those dog biscuits.

Bill Parker W8DMR
2738 Floribunda Drive
Columbus OH 43209

While your transmitters may be able to provide up to a kilowatt of power to the transmission line connected to the antenna, how much of that power reaches another ham's receiving antenna? And how much is needed to make the receiver work?

Typically, 50 microvolts is needed at the antenna terminals of the receiver to produce an S-9 signal. One S-unit represents a nominal 6 dB (decibel) level change.

Assuming the input resistance of the receiver is 50 ohms, how much power will 50 microvolts provide? Let's consult Dr. Ohm.

P (watts) = E^2/R.

Are we OK so far?

E = 50 μV = 50 x 10^{-6}V.

So $E^2 = (50 \times 10^{-6})^2 = 2{,}500 \times 10^{-12}$.

$P = 2{,}500 \times 10^{-12}/50 = 50 \times 10^{-12}$ watts, which is 50 picowatts, or 50 trillionths of a watt.

An S-9 signal is actually a high level. So what if the level of signal is only S-3? With an S-9 level equal to 54 dB and S-3 equal to 18 dB, it's 36 dB below S-9. A reduction of 36 dB means the signal has been lowered by a factor of 4,000 or 2^{12}. The 50 picowatts, when reduced by 6 S-units, lowers the input signal to 12.5 femtowatts. A femtowatt is 1 x 10^{-15} watt. What is the attenuation (in dB) if a kW is radiated and 10 femtowatts arrive at the DX station's receiver?

Attenuation = 10 Log (1 kW/10 femtowatts) = 10 Log (1 x 10^3 watts/10 x 10^{-15} watts) = 170 dB.

This amounts to one part in 100,000,000,000,000,000 of the original signal that started. Earth-moon-earth (EME) ham operators have attenuation paths of about 250 dB. High gain, narrowband receivers with low noise preamps are needed to work the 480,000 mile EME path.

As the signal travels in space it is also spreading, so only a very small fraction of the original kW is available to the ham located far away. The attenuation due to the signal spreading (the inverse-distance law) is called path loss. 73

BC Band Antenna Switchover Relay

A better way for Icom HF radios.

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

Many of the Icom HF ham transceivers—those with general coverage shortwave reception capabilities—require physically changing the HF antenna connection on the rear apron of the transceiver to enable your ham antenna to also be used as a BC band antenna. The changeover also requires the use of an SO-239-to-RCA phono connector adapter to adapt the normal transmission line PL-259 connector to the phono jack input on the radio. This isn't very handy for most of us—there must be a better way!

Fig. 1 shows one better way. It's a totally automatic system that provides a way around this inconvenience in the Icom IC-745 transceiver specifically; however, the principle can be used in most other Icom transceivers, though the details may vary slightly from one set to another. The receive antenna path is normally looped out the rear of the transceiver to provide access for a separate receiver. This loop is broken, and controlled by a small relay that feeds it to either the RX IN or BC IN inputs. You can use the schematic diagram in **Fig. 1** as a guide for finding the correct BC band voltage pick-off point in your own particular Icom model of transceiver.

The principles

Here then are the principles: The 8 volt "BC band enable" signal is tapped off of the junction of D-14, D-15, C-154, and L-43, and routed to an unused pin (# 24) on the IC-745's rear apron "accessory" Molex connector. It's then brought into a newly-built relay box containing a 9 volt SPDT relay which will be used to switch the HF antenna into the BC band antenna input on the radio anytime the BC band is selected on the dial (and all automatically). Quite a difference in convenience, while still maintaining the isolation of the BC band from the rest of the HF shortwave band as originally intended by Icom.

The three short output coax cables from the new relay box, which are terminated in RCA "phono" type connectors, do the RF signal routing. The only addition inside the radio itself is the single DC wire to accessory connector J3, pin 24. RG-58 or the miniature RG-174 cable would be ideal, but any shielded cable works OK. The relay and its connections can be housed inside any small project box you choose, then tucked neatly away behind the radio and out of sight. The new relay box only handles receiving level signals, so a power relay isn't needed and the transmitter's signal path is completely unaltered.

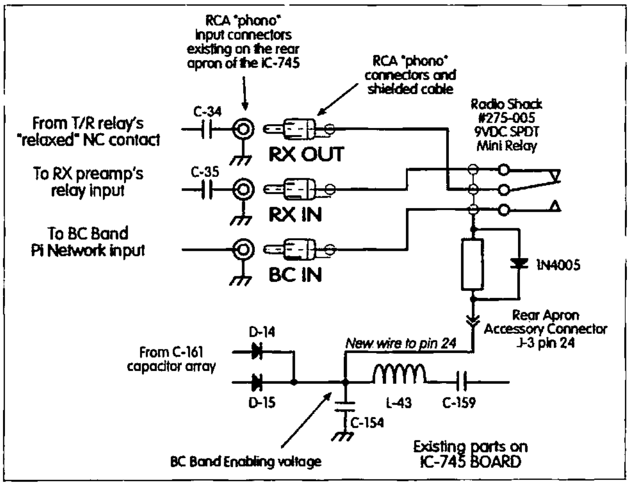

Fig. 1. Schematic diagram of the outboard switch-over relay that enables the HF antenna to be used for BC band reception in the Icom IC-745.

Finishing touch

I housed the relay and cable connections inside a 1" x 2" x 1" Sescom MPB-1* miniature aluminum project box and, in turn, mounted the box on one of the rear screws that hold the IC-745's heat-sink cover in place. Sescom's boxes are interesting because they are in "kit form," using flat aluminum sheet stock for the sides and end pieces, but held together with custom-made extruded aluminum angle at the four corners and then secured with four small Philips-head sheet metal screws on the top and bottom ends. They allow for nearly endless customization. This scheme affords a very neat, low-profile installation, and the aluminum box provides complete shielding for the relay and cable ends. The shielded cables between the box and the transceiver's inputs are literally just a few inches each so they don't affect the transceiver's performance. Once the switchover relay is installed the antenna will change input ports as soon as you go to the broadcast band. You'll never have to fumble with swapping cables on the back of your radio again!

"You'll never have to fumble with swapping cables on the back of your radio again!"

*The MPB-1 used by the author (and other boxes in the MPB series) are available from Sescom, Inc., 2100 Ward Drive, Henderson, NV 89015-4249 (1-800-634-3457 orders only or 1-702-565-3993 for information).

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

Last month I discussed some of the ways that digital information can be impressed onto a single signal. What I left out, though, is the mechanism for putting that signal over a radio wave. After all, the name of this column is "RTTY Loop," not "TTY Loop"!

Recall for a moment that the schemes we came up with last month basically involved assembling a group of on and off pulses into a sequence that would represent one letter, number, or machine function. The idea is to transmit these pulses, sequentially, on an amateur radio frequency.

Early modes

The first scheme tried, way back when radioteletype was first starting out, was called on-off keying. Very simple to understand, and conceptually the obvious first choice, on-off keying just keys the transmitter in step with the code pulses, creating what is in effect a very high speed CW signal. **Fig. 1** illustrates this technique; other figures are also grouped here for comparison. The advantages of this technique are related mainly to simplicity in transmitting: You merely hook the teleprinter to the key jack. Reception is also easy, with no need for the fancy circuits other techniques demand. The disadvantages of this simple mode relate primarily to interference susceptibility and fading. A nearby CW signal can wipe out an on-off TTY station, and fading can remove whole letters.

A better way to send RTTY is by presenting a constant signal for the MARK state, changing it in some way to represent the TTY signal. Changes may be introduced in amplitude, frequency, or by a superimposed modulating waveform. Direct amplitude modulation with the digital signal approximates on-off keying, with its attendant flaws.

FSK and AFSK

Over the years, a frequency modulation technique has arisen as the most-used amateur mode, either with frequency modulation of the RF carrier frequency, FSK (or frequency shift keying), or with frequency modulation of a superimposed audio signal, AFSK (or audio frequency shift keying).

In FSK, a carrier is shifted in frequency to correspond to MARK and SPACE. **Fig. 2** diagrams this nicely. This system, as are all to follow, is a redundant system. That is, information is obtainable by looking at either MARK or SPACE, even in the absence of either one. Remember that in on-off keying, if you lose the SPACE you have a steady MARK, and if you lose the MARK you have nothing. Transmission of FSK is accomplished by shifting the transmitter VFO in step with the digital signal, and reception by decoding either or both the MARK and SPACE. Done properly, this system is virtually immune to interference and, since fading normally affects only one of the MARK or SPACE frequencies at a time, proper use of the built-in redundance makes fading no problem either. The frequency shift involved may be anything from kilohertz to fractions of a hertz, which might be more properly called "phase shift." In amateur circles the original standard, before modern equipment, computers, and band cram, was 850 Hz; nowadays, most FSK signals are shifted only 170 Hz.

"The Radio Data Code Manual *includes just about every teleprinter communications scheme that exists, explained and diagrammed.*"

Unfortunately, FSK presumes very stable transmitters and receivers. The level of shift is certainly less than one kilohertz, and drift in either the transmitter or receiver of any significant degree would be intolerable. VHF transmitters, especially early ones, would not maintain this degree of stability. Use of an audio tone, shifted in frequency in a manner similar to FSK, became the standard on VHF links. This AFSK is more useful than it appears at first glance. Realize that transmitting tones over radio is not that different from transmitting tones over telephone wires, and this scheme forms the basis of all those computer modems, networks, and the World Wide Web.

Other techniques

Now, how about some alternative schemes? Two such techniques employed along the way used brief pulses to encode data, rather than longer segments. For example, with a "standard" 60-word-per-minute radioteletype signal, each data pulse is 22 msec long. What if a brief pulse was sent during each 22-msec window, with either its amplitude or position within the window representing the pulse's state? The resultant Pulse Amplitude Modulation (PAM), or Pulse Position Modulation (PPM), is shown in **Fig. 4**.

Having to transmit pulses sequentially imposes a limit on just how fast you can transmit, given that you can only divide a cycle so many ways.

The solution to that is to assign groups of pulse patterns to different frequencies. Thus, transmitting a sequence of frequency blips may encode quite a few more data bits. For example, rather than have one frequency for MARK and one for SPACE, suppose you had one frequency, say 500 Hz, for the bit pair "00," 1000 Hz for "01," 1500 Hz for "10," and 2000 Hz for "11." You could then send the "RY" sequence, 01010=R and 10101=Y, as 1011011011011011 in five pulses rather than 10. With each pulse taking the same time, you can double the speed. It is not hard to see that by making this a tad more complex, by making each data word longer and assigning more tone steps, speed could be increased even further. Not only that, but by employing data compression, an instruction could lump that sequence of five 1011 data words into a control word which says repeat times five, and the data word only once. This is, basically, how many forms of data compression work, including those involving data transmission.

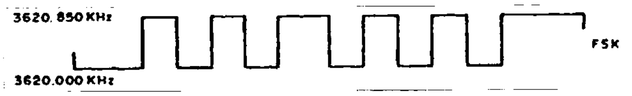

Fig. 2. In FSK, a carrier is shifted in frequency to correspond to MARK and SPACE.

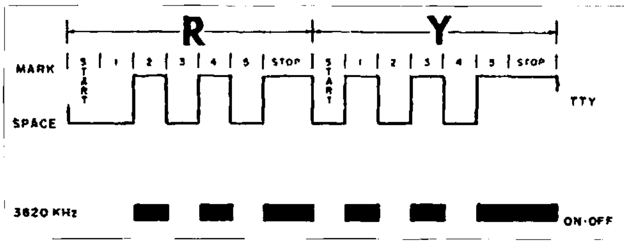

Fig. 1. On-off keying.

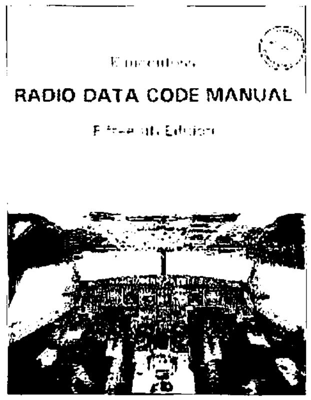

***Photo A.** The* Radio Data Code Manual *is available for DM70 from Klingenfuss Publications.*

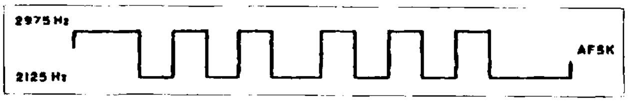

Fig. 3. AFSK, audio frequency shift keying.

All of these schemes have concerned themselves with only one end of the data transmission scheme. But transmission implies reception, and there are quite a few techniques for enhancing data interchange as well, other than the simple "I talk, then listen to you" model. This is where we get to packet, AMTOR, and the like, but this is also for a future discussion.

New reference book

Reference books have long been lacking in this area, but a new one has been published which includes just about everything the digital amateur could want in the way of such information. Our old friend, Joerg Klingenfuss, who has been writing authoritative tomes for about 30 years now, has published his 15th edition of the *Radio Data Code Manual*. It includes a raft of meteorological codes with detailed examples, over 10,000 meteorological stations indexed, aeronautical telecommunications abbreviations, company and aircraft designators, CW and RTTY alphabets for Arabic, Chinese, Cyrillic, Greek, Hebrew, Japanese, and other non-Latin alphabets, and just about every teleprinter communications scheme that exists, explained and diagrammed.

Photo A. shows the cover of this 600-page publication, which is available for DM70 from Klingenfuss Publications. Check out Jeorg's stuff on his home page at: http://ourworld.compuserve.com/homepages/Klingenfuss/ or drop him a letter at Klingenfuss Publications, Hagenloher Str. 14, D-72070 Tuebingen, Germany.

Stop by the RTTY Loop home page as well, at: http://www2.ari.net/ajr/rtty/ for columns, features, and other items of interest to digital amateurs. The full listing for the RTTY Software collection is online there, but it is also available by sending a self-addressed, stamped envelope to the address at the head of this column, for those of you who are not yet online or who cannot download from the Web. I look forward to your comments and questions, as always, at ajr@ari.net, Marc WA3AJR@aol.com, or 75036.2501@compuserve.com.

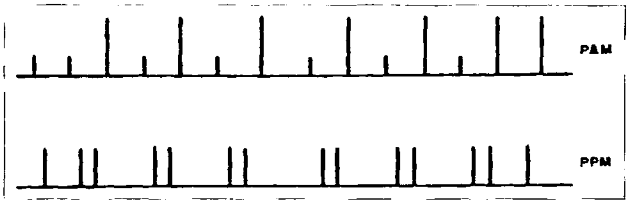

Fig. 4 . Pulse Amplitude Modulation (PAM), or Pulse Position Modulation (PPM).

NEVER SAY DIE

personal computer revolution almost entirely.

Bill Gates and Steve Jobs, the two most successful personal computer pioneers, were both college-dropout entrepreneurs. They're both billionaires now, thanks to the blindness (aka stupidity) of the computer industry professionals.

Today this whole scene is being replayed in the world of physics and power. Will the future titans of power be today's cold fusion pioneers? It's most likely, given the refusal of universities and power industry firms to recognize this new technology's potential. It's the same blindness that killed Centronics, which was the largest manufacturer of printers in the world—for minicomputers. Microcomputers blew them away.

When we're able to generate power at a tenth the cost of fossil fuels such as coal, oil, and natural gas, there will be no power bloc strong enough to stamp this out.

The fuel and power companies are working on the basis of "to hell with tomorrow, let's make all we can right now." So

Above & Beyond

VHF and Above Operation

C. L. Houghton WB6IGP
San Diego Microwave Group
6345 Badger Lake Ave
San Diego CA 92119
Internet: clhough@aol.com

2304 MHz—A Club Project

Members of the San Diego Microwave Group have embarked upon an ambitious construction program, aimed at increasing our amateur ranks with operational transceivers for the 2, 3, and 5 GHz amateur bands. Our intent was to put together the simplest basic transceiver for use at our monthly group meetings. Kerry N6IZW's intent was to construct a transceiver each month for the 2, 3, and 5.6 GHz bands. Sounds like a very ambitious construction project; however, the driving force was to make some of these rigs usable in the June VHF/UHF contest.

This project was not intended to be a backbreaker, but rather an interesting construction project in our lower microwave bands. Nothing was set in stone as a rigid design; the only requirement was that the rig should be capable of operation with either narrowband FM or SSB. This meant that the basic design has to be, at minimum, a local oscillator, a mixer, and an antenna. The most critical part of any system is the local oscillator, as its stability must be sufficient to support operation on narrowband FM as well as single-sideband.

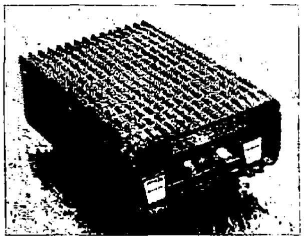

Photo A. Basic cabinet structure (old-style) from Qualcomm. Front panel contains DC power connector, input IF/output RF coax connectors. Toggle switch used for manual RX/TX transfer control.

The 10 GHz band that microwave equipment can be obtained for is just what this column is all about: different material being used to construct transceivers from scrounged material obtained from surplus, in addition to using the Qualcomm 3036 PLL synthesizer chip. This chip and the surplus PC boards our group has available have given us the ability to provide for frequency generation for these converters easily and inexpensively. It is fitting that the local oscillator (LO) is the basic building block of all converters. The main premise here is that if you can find an LO for use in a converter at one or several of our microwave bands, the other parts for construction of a transverter are not far behind.

Our new project

The first rig to be constructed will be for 2304 MHz; the month following, it will be a rig for 3456 MHz; and the month after that, a rig for 5760 MHz. What shows up and who constructs a rig for which frequency has been left up to the individuals wishing to participate. I am sure those who participate will not produce a rig for each of the frequencies as this is quite ambitious, but I am also sure that there will be quite a few different rigs to make things interesting, just to see what shows up for testing in preparation for the June VHF/UHF contests.

The prime ingredients in any project are initiative and direction, and we seem to be blessed with lots of those qualities within our group. Pete W6DXJ had the head start on this frequency as his station was partly assembled prior to the beginning of our building program. Pete had been prodding us to get on 2304 as well as 1296 MHz, but when we announced the fast-paced drive to construct a 2304 MHz rig for next month, he scrambled just as fast as all of us to finish a 2304 MHz transceiver.

Well, the next month came and several 2 GHz rigs were constructed. Pete W6DXJ brought his station, as did Kerry and I. This gathering, at Kerry's home, proved to be quite enjoyable. We made many contacts using both wideband FM and SSB operation. One funny aspect was that we all had selected the same IF frequency on 2 meters (144.1 MHz using a 2160 MHz local-oscillator frequency).

When we fired up the transceivers, we found that all stations being co-located produced very good contacts on 2 meter feedthrough. This produced quite a confusion factor at first, until we separated the 2 meter bleed-through from the 2304 MHz actual RF. We directionalized the test antennas at each other and when we obstructed the direct antenna's path we would get a 5 to 6 S-unit decrease in signal strength. We covered the antenna up with our hands on the receiving end of the path for this test. All stations were located inside the garage or out on the patio for initial tests.

On the next cut of operation, Kerry and I tested a path of some four miles, with an excess margin of 60 dB in signal on this short path. We were using about 25 mW transmit power and a 30-inch dish for this test. While this was a peanut-whistle, it was still a working station.

Construction techniques

First, let's describe Pete W6DXJ's station. This station was started as a kit from Microwave Modules, one of their series of no-tune transverter kits for 2304 MHz. Pete had modified the original PC board circuitry; he removed the crystal oscillator multiplier circuits and replaced them with a microwave synthesizer that our group makes available. This modification was done to provide increased frequency stability for the local oscillator, making exact frequency setting at 2304 MHz a reality.

Now, there is nothing wrong with a crystal oscillator that operates near 100 MHz and its associated multiplier circuits used to increase its frequency to the microwave range. The problem is that the crystal has a frequency stability problem you should be aware of. As with any circuit,

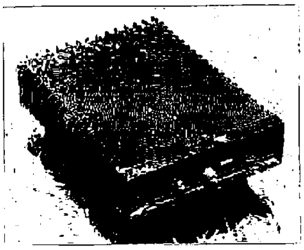

Photo B. New-style cabinet that is shorter in height than old-style cabinet. Cabinet provides a hardened interior for protection of microwave circuitry, and provides an RF tight-enclosure.

there are liabilities and attributes. On the crystal's side of things, it produces a very clean local oscillator signal (low-phase noise products). However, its frequency accuracy (stability) is of concern. Its error increases with frequency multiplication as it is subject to the effects of temperature and voltage shifts.

The solution that our San Diego Microwave Group chose was to replace the crystal circuitry with one of our Qualcomm surplus synthesizers, because we had the material and wanted to make use of it (the prime directive: locating inexpensive materials). The synthesizer was frequency-agile, so we reprogrammed it to provide 2160 MHz directly from a VCO-controlled oscillator co-located on the Qualcomm synthesizer PC board. It maintains high accuracy because it is driven by a 10 MHz reference oscillator which is accurate to 1 hertz in 10 MHz, providing accuracy at 2160 MHz to within a few hundred hertz.

This synthesizer output is about +10 dBm and is a direct connection to the mixer. However, all is not perfect here, as you must realize. While the synthesizer is quite frequency-agile, it does have some noise products. Phase noise is degraded in comparison to a crystal oscillator. With a synthesizer, phase noise is something you have to live with, compared to a crystal operating at 100 MHz and multiplied to the 10 GHz band (a test point for evaluation of the crystal and synthesizer). The crystal oscillator produces a spectral-clean local oscillator signal (at 10 GHz) with phase noise products down about 70 dB or

more. Comparing this to the synthesizer when multiplied to 10 GHz (an equal playing field for measurements), we measured phase noise products 35 dB down.

Now, you say this is worse than the crystal oscillator. Well, yes it is, but consider the simplicity and ease of converting a system that has excellent frequency stability. The synthesizer has a frequency variance at 10 GHz of less than *several hundred hertz!* When used at lower frequencies, such as 2304 or 3456 MHz, it is quite superior to most anything else. (Yes, I make these surplus synthesizers available. When you have something that is relatively inexpensive and operates very well you can't stop beating its drum. These synthesizers can be converted from their original state to a new frequency much more easily and with minimal test equipment and cost, than other methods such as crystal oscillators and associated multiplier strings.)

Crystal vs. synthesizer

There has been much discussion about the merits of crystal oscillator vs. synthesizer-controlled oscillators, and many debates about each method's merits and problems. However, at the amateur level there are no "deep pockets." For me, the bottom line is that when a crystal can be made as accurate and inexpensive as the synthesizer, then I will move over to the crystal. If you have the crystal and it is the only oscillator you have, don't get me wrong—*use it.*

The synthesizer is a very good oscillator and works well when we forget about the mystical properties it is supposed to have. I hope I have helped to show that it can be used with relative ease by modifying commercial material for microwave frequency generation. The prime benefit is very high frequency stability, comparable to VHF radio operation. Having this stability in a system removes one more obstacle, making that rare or interesting contact easier.

Once you have tried high stability operation, you will not miss the hit-or-miss operation of tuning for contacts. It can be done, but take my word for this; when you say, "I'll meet you on 2304.100 MHz," I know I am there. When the other station so equipped transmits, I only have to adjust the clarifier to make contact. If only one station in your area operates with frequency synthesis, then certainly that station can be used to set others on frequency, removing that element from preventing you from making contacts. Your enjoyment will increase when frequency disparities can be reduced or eliminated. My recommendation is: don't rotate the dial up and down the band searching for a 2-kHz-wide signal in the vast megahertz bands.

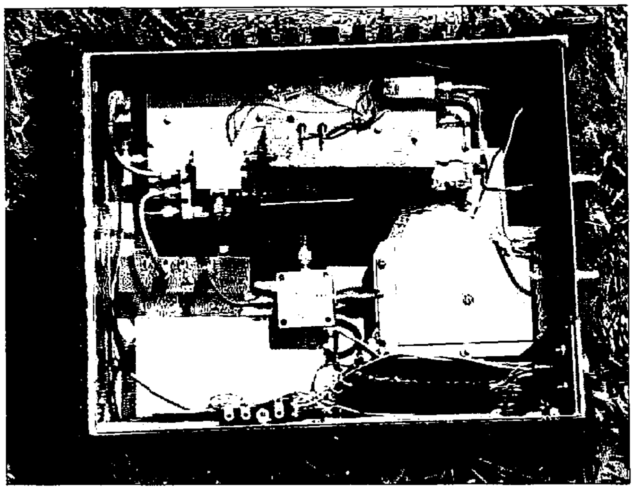

***Photo C.** Interior of 2304 MHz converter. The Qualcomm 3036 synthesizer is at bottom right in the metal container; the 10 MHz crystal is wrapped in black rubber for shock resistance. The amplifiers required -24 volts, so I used an LT-1070 switcher to convert from +12 volt to -24 volts. Top: receive and transmit amplifiers, mixer in the middle.*

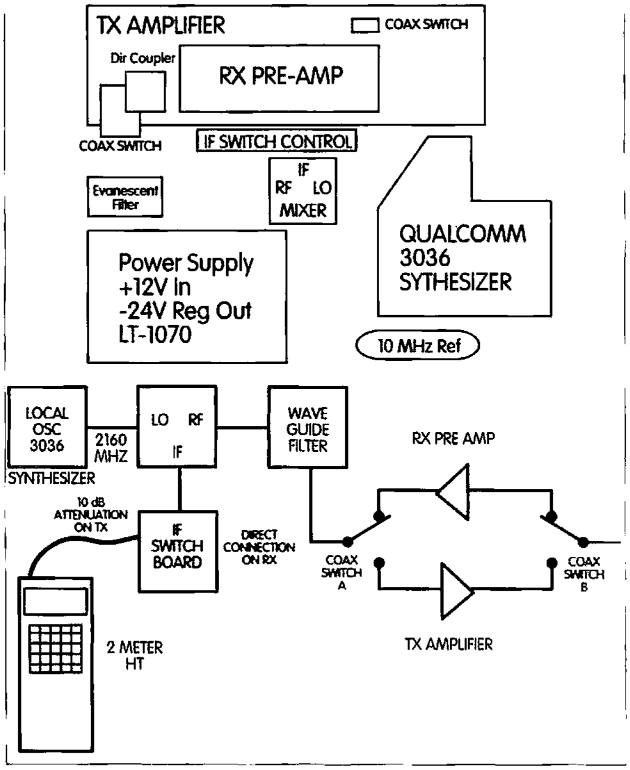

Fig. 1.** Block diagram and parts placement diagram of the 2304 MHz converter shown in **Photo C.

Don't shoot down the vast frequency available on the microwave bands; these lend the amateur operator the ability to explore many new and different modes of communications. There has been much interest generated in the new computer innovations for packet operation using very high-speed modems with very large bandwidths. This type of system, as well as experimentation in video transmission, require megahertz-frequency bandwidths for test and development by amateurs using amateur microwave frequencies. That is one of the reasons that we have attempted to push forward construction on these bands. My construction project might be part of the development of other modes of operation yet to be envisioned.

The ability to do this work on the amateur bands has enabled a free-thinking flow of new experimentation in electronics, for pure research and for developing untried concepts at the amateur level. I can't describe an exact product that has been developed in this manner. However, when ideas can take on this amateur electronics type of development, train and apply them to tests and implementation; new technology may be the result. Amateur radio is not just a hobby to a lot of amateurs employed in the electronics industry today. To many of us, it has become an outlet for personal satisfaction and enjoyment—pursuing new and interesting techniques. It is to these innovators that we owe much, and they provide a source for new and interesting material.

These are some of the benefits and problems associated with these different types of oscillators, like the synthesizer and the crystal-multiplied oscillator. Take a look at the concerns and decide for yourself. The bottom line on what to recommend is what you are able to locate and use inexpensively to construct your system. That's the real choice for the pure enjoyment of the task. That is what surplus is all about to the radio amateur: inexpensive alternatives to solving a circuit problem.

So much for innovation. Let's get back to the local oscillator and the rigs that were constructed.

W6DXJ's project

Pete W6DXJ had a long loop yagi antenna for use at 2304 MHz that coupled to his transverter, purchased from Microwave Modules. Pete made a few modifications to the Microwave Modules transverter's basic circuit. He included a low-pass filter consisting of an RFC and a 20 pF capacitor in the 144 MHz IF circuitry. He did not build the crystal multiplier oscillator string; he used one of the Qualcomm synthesizers instead. Luckily, the output frequency from the crystal string was a frequency that the synthesizer could generate: 2160 MHz.

The remainder of Pete's rig was original microwave modules circuitry. Pete commented that the synthesizer approach was quite easy, but he had plans for a much more personal pursuit for excellence in construction of a crystal oscillator string, providing external phase-locking of the crystal to a high-stability 10 MHz crystal reference. This more expensive approach would yield a great low phase noise oscillator and a frequency-accurate unit.

What Pete intends to construct is a phase-locked loop that will maintain the main oscillator crystal at a precise frequency, eliminating the frequency uncertainty of home-constructed oscillators. It is to be phase-locked to a submultiple of 10 MHz. Kerry and I developed the circuit many years ago to lock Frequency West "Brick"-type oscillators. This is too much to go into this month, so I will cover the synthesizer and the phase-locked circuits next month, along with the 3456 MHz rigs.

Antenna switching was done with only one coaxial relay as the microwave module system used separate receiver and transmitter amplifier strings. Power supply requirements were easier in this system as almost all of the power could come from a single 12-volt DC-regulated unit.

The rigs that Kerry and I constructed were almost identical, mainly because we found two sets of commercial junk to use in our transceivers. An old Collins radio for 2.3 GHz provided us with both receiver preamplifiers and a 100 mW transmit amplifier. The remaining local oscillator and other circuits had to be constructed from scratch or modified from Qualcomm surplus material. We used surplus Qualcomm aluminum cabinets to contain our microwave circuitry. These cases are heavy heat-sinked, ripple-finished, and quite attractive. They afford a nearly bulletproof transportable case for field use of our microwave equipment.

The synthesizer we used was reprogrammed for 2160 MHz, driving a double-balanced mixer. The output of the mixer was fitted with a evanescent (waveguide below cutoff) filter that is reasonably sharp and easy to construct with simple tools.

Next month I will cover the detailed information on the evanescent filter and provide detailed information on converting the Qualcomm synthesizer for amateur radio use. Best, 73 Chuck WB6IGP; clhough@aol.com.

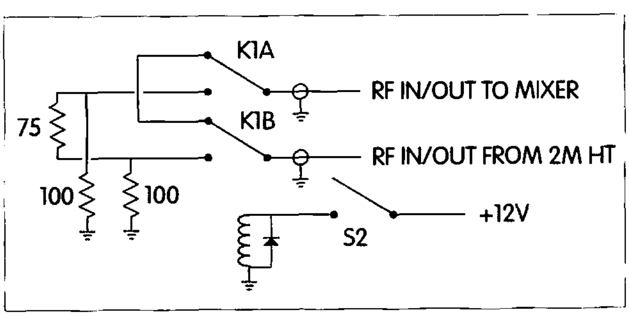

Fig. 2. Simplest IF switch for 144 MHz transfer of RX/TX IF switching. Operation uses toggle-switch actuated coaxial relay. Adjust value for transmitter attenuation. I used a 10 dB attenuator (two each 110-ohm resistors, shunted by 75 ohms); other values are possible (20 dB equals two each 68-ohm resistors, shunted by 270 ohms). Use carbon composition for RF use; 1/2 watt suitable for low power transceivers (less than 1 watt power output).

NEVER SAY DIE

Continued from page 71

how long will the coal last? Fifty-seven percent of our electric power in the US is generated by burning coal, and they're using over one *billion* tons of coal a year. A couple generations or so down the line our descendants will have to make do with a world stripped of coal, oil, and natural gas, just as most of the world has already been stripped of old-growth forests. It's interesting to fly over the Northwest's forests and see thousands of acres of what recently were forests, with every single tree cut down! Clear cutting. I'm thinking more and more as an ecologist, though I haven't been converted into a fanatic. But we sure do need to get cold fusion power generators researched and developed.

So, are you going to be one of the people who reads about what happens or are you going to be one who helps make things happen? Remember, just about every major breakthrough in science has been made by amateurs. Not all of the personal computer pioneers got to be billionaires, some just made millions. Oh, well, there are always winners and losers.

I urged my *73* readers to get into microcomputers 20 years ago and hundreds have thanked me for helping them to break loose from their jobs to start their own companies. I don't think there's ever a hamfest where one or two hams don't thank me for kicking them in the pants. Well, I'm still after you to do better ... for yourself, your kids, our country, and the world. I want you and your family to be healthy and prosperous. So I'm reading every book I can find that I think may help you toward wisdom and a longer life. And I'm finding some amazing books.

How difficult and expensive is it to be a cold fusion pioneer? The leader in America today is Dennis Cravens, a science teacher from a small Texas community college who put together a lab in his garage. His total investment was under $5,000! He's recently moved to New Mexico and is helping Jim Patterson develop his Patterson Patented Cell. Jim is an inventor and he's my age. Dennis is in his 30s.

A Waist Is a Terrible Thing to Mind

A somewhat sobering statistic emerged from my TV. I was tuned to a PBS health show and it was pointed out that of the few people who manage to live to 85, over 80% are seriously impaired. Is that what you want to look forward to? If you are one of the few to make it to 85? Most people drop dead of heart attacks and cancer long before that. Heck, I'm already to the age where half of my contemporaries are already dead.

The comforting thought is that hardly any fat people live that long, so if you've got a big gut you at least won't have to worry about being seriously impaired in your later years, because there aren't going to be any later years. Having been fat most of my life, I know all about the see-saw of diets that about 2% of fatties manage to overcome. I've been there and done that. Done it endlessly.

I know how delicious ice cream is. I know all about Danish and juicy hamburgers. But I also know I'm having enough fun irritating the heck out of you to stick around a while and keep in touch with my fat friends via my Ouija board instead of 75 or 20m. I know about the poisons which can knock down my immune system and allow cancer and other miseries to take over. Anyway, as I've mentioned before, a little over 20 years ago I finally decided that enough was enough. I went on a 1,500 calorie diet and stuck to it through thin and thin, dropping about two pounds a week until I'd lost 85 pounds. And, by changing my eating habits, I've kept it off.

Can the Bioelectrifier reset your appestat, causing your body to shed all that lard, as Bob Beck claims? I haven't heard of anyone else doing it yet, but it's still too early. Most of the research with it has been toward eliminating viruses, microbes, parasites, yeasts, and fungi in the blood. I am hearing from fairly healthy people who've experimented with the gadget and have achieved an even higher level of health. I hope that more doctors will try to overcome their indoctrination by the pharmaceutical industry and help research the potential for this approach.

Record DX on 10 GHz

Although most ATV activity in the US exists on the 70 cm and 23 cm bands (some groups also utilize the 900 MHz band), it's rare to find much going on in the higher frequencies.

One of the best-kept secrets up here is the 10 GHz region. It's one of the final frontiers for ATV, a place where most equipment must be home-brewed. Fortunately, this is one of the easier bands to build equipment for, due to the availability of surplus Gunnplexers™ and satellite TV receivers. The 10 GHz band seems to be used mostly for short-haul dedicated links for repeater systems and special events,

but there are a few dedicated folks who enjoy pushing this band to the limit. Many ATVers are deterred by the misconception that the distances that can be covered fall far short of what you can do on 70 cm. This may be true with low-power systems (the typical Gunnplexer™ system runs less than 100 milliwatts), but when you factor in tropospheric ducting, higher power, good antennas, and the ability to aim your antenna precisely, you can achieve remarkable DX on this band.

Go the distance

On May 18th, F1JSR set up his 10 GHz system on the island of Corsica in the Serra di Pigno (grid square JN42RQ) at a height of 960 meters (3148 feet). His ATV system consisted of a DRO synthesized transmitter on 10.450 GHz fed into a TWT (Traveling Wave Tube) amplifier, which delivered 20 watts to a 40 cm diameter (15.7 inches) Ikea parabolic dish. For receive, he had an off-set feed antenna of 85 cm diameter (33.5 inches), a non-modified Astra LNB, a +500 MHz converter which fed into a standard TVRO satellite receiver, in parallel with a voice receiver, to help aim the dish.

From his vantage point at Sierra de Montseny near Barcelona, Spain (grid square JN11ET and an altitude of 1650 meters, 5412 feet), Michel Vonlanthen HB9AFO set up his ATV system. He had a DRO transmitter on 10.480 GHz driving a 1 watt solid-state power amplifier, which fed a 40 cm (15.7 inches) diameter parabolic dish. His receive setup consisted of a 1 meter (39.38 inches) diameter dish with a high precision az/el gear system to point his antenna accurately.

Photo A. *Michel Vonlanthen HB9AFO successfully completes a two-way 10 GHz ATV QSO of 592 km (368 miles) with F1JSR on the island of Corsica on 10 GHz ATV, from his vantage point near Barcelona, Spain.*

Photo B. *F1JSR sets up his station on the island of Corsica.*

This fed into a modified Astra LNB with a noise factor of 0.7 dB and a modified AR3000 receiver followed by a narrowband ATV FM demodulator, in parallel with a normal TVRO satellite receiver.

The distance between these two stations was 592 kilometers (368 miles). The 10 GHz FM ATV contact was two-way, with the signals varying between P0 and P5 with color. Quick signal fluctuations were observed during the contact, probably due to the strong wind, fog, and intermittent rain in Corsica. Two days earlier, a similar QSO was successful over a 574 kilometer path (357 miles) between F1JSR (at the same location on the island of Corsica) and HB9AFO from a different location on Pic de Nore, in the Department of Tarn in France (JN13FJ). This contact lasted more than two hours. Both contacts were made around sunset.

"You can achieve remarkable DX on this band."

More details will be published in the French and Swiss ATV publications *B5+* (ANTA) and in *Swiss ATV News*. A VHS video cassette will be available soon showing this QSO. If you would like a copy, write: Swiss ATV, P.O. Box 301, 1024 Ecublens, Switzerland. *Thanks to Michel Vonlanthen HB9AFO for the above information and the photos.*

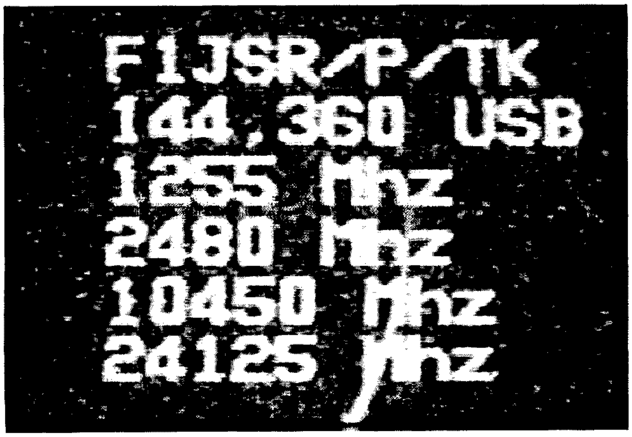

Photo C. After traveling 592 km (368 miles), this is the reception of F1JSR/P/TK's 10 GHz ATV picture as received by EA3/HB9AFO/P. in the Sierra de Montseny, Spain.

NEVER SAY DIE

Continued from page 76

the latest $10 AIDS booklet from Radio Bookshop and invest $10 more for a copy of Bob Beck's talk at the 1996 Global Science Congress. It's a lulu. He lost 85 pounds without dieting, and also regrew a full head of hair. And he was there as living proof. No more fat, bald old Bob. It took years off his age.

It's your choice: an early death via fat, a lingering death via poisons, or vibrant health when you're thumbing your nose at the Social Security people. But this is a choice you have to make now, not after you're in the hospital with cancer, a heart attack, stroke, or tied to a rocking chair in a nursing home as a gibbering veggie.

Cancer

A high percentage of us are going to die of cancer, but how much do you really know about it? For instance, are you aware that despite the 25-year multibillion-dollar war on cancer we've waged, that "medical science" has not extended the life of cancer patients one day? In fact, prostate cancer patients have a longer probable life if they are not treated than if they are. Without treatment you can expect to live around 15 years. With treatment you'll probably live less than five years.

There are several alternative approaches which have been successful in curing cancer, but since they don't involve pills or shots, there is no way for the pharmaceutical industry to make money with them, so they have not been investigated. Plus there's no group to put up the $250 million it now takes to get a new medication or procedure approved by the FDA … a 10–15-year process which keeps thousands of government employees from getting more productive work.

How about it—will I be shaking your hand at Tampa in November?

Lawyers, Lawyers!

Our media compatriots will no doubt try to make a big deal over our lawyer's decision to

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the December issue, we should receive it by September 30. Provide a clear, concise summary of the essential details about your Special Event.

AUG 25

WOODSTOCK, IL The Tri-County Radio Group, Inc. will hold its Hamfest and Computer Show at the McHenry County Fairgrounds located just north of Rte. 14 on Rte. 47, beginning at 6:30 AM for the Flea Market and 8 AM for the exhibitors. Setup available on Sat. by appointment, or at 6:30 AM on Sun. Talk-in on 146.52 simplex. Reservation deadline is Aug. 11th. For more info, or reservations, write to *T.C.R.G., P.O. Box 3107, Skokie IL 60077-6107;* or call *Robert N9KXG, (847) 658-1678.*

AUG 31

ALAMOGORDO, NM The Alamogordo ARC will hold their 12th annual Hamfest at Otero County Fairgrounds, on White Sands Blvd., 8 AM–4 PM. ARRL Forum, MARS Forum, Flea Market, VE Exams, Banquet. Talk-in on 146.80(-). For tables and info, call *Larry Moore WA5UNO, (505) 434-0145;* or *Jim Patton N7IOM, (505) 439-8349.*

SEP 7

ERIE, PA The Erie Hamfest '96 will be sponsored by the Radio Assn. of Erie, 8 AM–2 PM, at Franklin Twp. Fire Hall. VE Exams will be held at 9 AM at Franklin Center Methodist Church (1 mi. north of the Hamfest on Rt. 98). Flea Market: vendor setup Fri. eve. 6 PM–midnight, and Sat., 6:30 AM. For reservations and info, contact *Chris Robson KB3A, 5560 Bear Creek Rd., Fairview PA 16415. Tel. (814) 474-1211; E-mail: crobson @ moose.erie.net.* Talk-in on 146.61(-) (W3GV).

UNIONTOWN, PA The Uniontown ARC will hold its 47th annual Gabfest at the club grounds located on Old Pittsburgh Rd., beginning at 8 AM. Free tailgate space with reg. Talk-in on 147.045(+) and 147.255(+). Contact *Carl WA3HQK* or *Joyce KA3CUT Chuprinko, Rt. 6 Box 231-CC, Morgantown WV 26505. Tel. (304) 594-3779.*

SEP 8

DARTMOUTH, MA The Southeastern Mass. ARA, Inc., will hold their 20th annual Flea Market 9 AM–3 PM on their clubhouse grounds at 54 Donald St., behind the Stackhouse St. Fairgrounds. Setup begins at 7 AM. Talk-in on 147.00 Rptr. Contact *Bill Miller, (508) 996-2969.*

DUBUQUE, IA The Great River ARC, Iowa Antique RC and Historical Society, and the Tri-State Computer Users Group will sponsor a Hamfest/Radiofest/Computer Expo 8 AM–2 PM at the Dubuque County Fairgrounds on Old Highway Rd., west of Dubuque. Dealer, Flea Market, Tailgating and VE Exams at 10 AM. Talk-in on 147.84/.24. Contact *Loren Heber NØYHZ, (319) 556-5755; Jerry Lange KBØVIK, (319) 556-3050;* or *Jerry Ehlers NØNLU, (319) 583-1016.* Write to *G.R.A.R.C., P.O. Box 546, Dubuque IA 52004-0546.*

SEP 13–15

PEORIA, IL The ARRL Nat'l. Convention at SuperFest '96 will be held at the Peoria Civic Center. It will showcase the latest innovations and technologies available to amateur radio operators. There will be forums and seminars on topics ranging from "Improvements for Club Operation" to "Exploring the Internet & the World Wide Web" to "Satellites & Antennas for HAMS." Exhibitors contact *R&B Productions, (309) 693-9667.* For general info, call *Ron Morgan KB9NW, General Chairman, (309) 692-3378. E-mail: SuperFest @ AOL.com.*

SEP 14

PRAIRIEVILLE, LA The Ascension ARC will hold its annual "Gonzales Hamfest" at the Gourmet Catering Inc. bldg. on Hwy. 73. Setup at 7 AM; general admission at 8 AM. VE Exams, Fox Hunt. Dealer and swap tables available. Contact *AARC, c/o Shane Dugas KK5LC. 37150 Swamp Rd., Prairieville LA 70769. Tel. (504) 673-8369.*

SEP 14–15

MELBOURNE, FL The Platinum Coast ARS will host their 31st annual Melbourne Hamfest in the Melbourne Auditorium, 625 E. Hibiscus Blvd., 8 AM–5 PM Sat., and 9 AM–4 PM Sun. Talk-in on 146.25/.85 Rptr. For info on tickets/tables, contact *Larry Sexton KF4EJB, 7005 Dogwood Dr., Cocoa FL 32927. Tel. (407) 636-8826;* or *Al Hudson N4PTM at E-mail ahudson@iu.net.*

SEP 15

HAMILTON TWP., NJ FallFest '96 will be held by the Delaware Valley Radio Assn. at Tall Cedars of Lebanon picnic grove on Sawmill Rd. Open to sellers at 7 AM, buyers at 8 AM. Talk-in on 146.670(-) Rptr. For more info, call *(609) 882-2240.* No advance reg.

MT. CLEMENS, MI The L'Anse Creuse ARC will host their 24th annual Swap and Shop, 8 AM–2 PM, at L'Anse Creuse H.S. in Mt. Clemens. VE Exams at 11 AM; contact Don WA8IZV, (810) 294-1567, Prodigy ID SSTG41a. New and used amateur radio equip., electronic parts and equip., computer and software. Trunk sales. Sep. 7 is the deadline for advance prepaid reg. Talk-in on 147.08(+) and 146.52 simplex. Make checks payable to *L'Anse Creuse ARC,* and mail with SASE to *Ralph Irish WA8GDT, P.O. Box 180122, Utica MI 48318-0122.* For more details call *(810) 731-6760 or (810) 651-7387.*

NEWTOWN, CT The Western CT Hamfest will be held 9 AM–2 PM at the Edmond Town Hall, RT 6 (Exit 10 on I-84). Setup at 7 AM. Talk-in on 147.12/.72. New Equip. Dealers, Flea Market, Tailgating, Computers. Contact *John Ahle N2DVX, P.O. Box 3441, Danbury CT.06813-3441. Tel. (203) 438-6782.*

SEP 21

LEXINGTON, NE An Amateur Radio and Antique Radio Consignment Auction will be sponsored by the Heartland ARA and the Mid-Nebraska Antique Radio Club, at Knights of Columbus Hall, 6th and Taft St. Doors open at 8 AM; auction begins at 11:30 AM. Talk-in on 147.135(+). Contact *Hoppy W4YDN, (308) 987-2161; E-mail: rh84859@ltec.net;* or *Randy WBØSAO, (308) 987-2312.*

SANTA ROSA, CA The Sonoma County Radio Amateurs, Inc. will hold their annual Swapmeet, Auction and VE Exams at the Holy Ghost Hall, one mi. north of Sebastopol CA, at the corner of Hwy. 116 and Mill Station Roads. Setup at 6:30 AM; general admission at 7:30 AM. For more details, contact *Rick Reiner K6ZWB, 2120 Slater St., Santa Rosa CA 95404. Tel. (707) 575-4455.* Or write to *Sonoma County Radio Amateurs, Inc., P.O. Box 116, Santa Rosa, CA 95402.*

SEP 21–22

ANCHORAGE, AK The Anchorage ARC will celebrate its Silver Anniversary Hamfest at the Kincaid Park Outdoor Center in Anchorage. VE Exams, FCC Commercial Radio License Exams, Alaska QSL Bureau, Demos, Guest Speakers, and annual Country Store. For booths, contact *Robert Wilson AL7KK, P.O. Box 110955, Anchorage AK 99511-0955. Tel. (907) 248-0976* or *(907) 271-5304.*

VIRGINIA BEACH, VA The 21st annual Virginia Beach HamFest & Computer Fair. ARRL Roanoke Div. Convention will be held at the Pavilion Convention Center in Virginia Beach. Forums, Guest Speakers. Show hours Sat., 9 AM–5 PM and Sun., 9 AM–4 PM. No smoking allowed in the Pavilion. For more details, contact *Lewis B. Steingold W4BLO, (804) 486-3800,* or *(804) HAMFEST. FAX (804) 486-0757.*

SEP 22

ADRIAN, MI The Adrian ARC Hamfest and Computer Show will be open at the Lenawee County Fairground, 8 AM–2 PM. VE Exams, Forums, Trunk Sales. Talk-in on 145.37(-). Contact *Brian Sarkisian KG8CO, 139 N. Main St., Adrian MI 49221. Tel. (517) 265-1537;* or *E-mail: gbishop@tc3net.com.*

COTTLEVILLE, MO The St. Peters ARC Swapfest will run 7 AM–1 PM at St. Charles County Comm. College Campus, 4601 Mid Rivers Mall Dr. Flea Market, VE Exams. Talk-in on 145.41 MHz and 444.275 MHz. Contact *Jay Underdown WØOGS, 58 Judy Dr., St. Charles MO 63301. Tel. (314) 723-4200.*

SEP 26–29

ACAPULCO, MEXICO The 55th Nat'l. Convention of the Federation of Mexican Radio Experimenters (member of the IARU) will be held in Acapulco. Conferences, Workshops, Extraordinary General Assembly,

Entertainment. For details. write to *Cesar Figueroa V. XE1KFV, FMRE, Apartado Postal 907, 06000 Mexico D.F., Mexico. Tel. 011-52-5-563-1405 (from the USA). Internet: FMRE@supernet. com.mx*. Stay over at the 5-star-rated Hotel Hyatt Regency Acapulco.

SEP 27–29

WALLA WALLA, WA The W7DP Walla Walla Valley ARC will host their 50th annual Hamfest and ARRL SE Washington Sec. Convention at the Washington Nat'l Guard Armory, 113 So. Colville (corner of Colville and Poplar Sts.) in Walla Walla. Skywam Seminar, Scavenger Hunt, Flea Market, and more! Contact *David L. Pence KB7WRT, Hamfest Chairman "W7DP," P.O. Box 321, Walla Walla WA 99362;* or call *(509) 525-2529*. Talk-in on 146.960/.360.

SEP 28

ELMIRA, NY The Chemung County Fairgrounds in Horseheads **NY** will be the site for the 21st annual Elmira Internat'l Hamfest-Computerfest. The event is open 6 AM–3 PM. For VE Exams (on site at 0900), call *Bill (607) 962-1134*. Walk-ins accepted. Dealer inquiries will be handled by *Jay at (607) 733-0761*. For ticket info, contact *Dave Lewis, RD1 Box 191, Van Etten NY 14889. Tel. (607) 589-4523*. Talk-in on Rookies Rptr. 147.96/.36 or 444.20.

HUDSONVILLE, MI "Super Swap 96" will be presented by the Grand Rapids ARA Inc., 8 AM–1 PM, at Unity Christian H.S., 3487 Oak St. Talk-in on 147.26 Rptr. (94.8). Contact *Dave Devos KF8QL, 8111 Hanna Lake Rd., Caledonia MI 49316. Tel. (616) 698-7022.*

SEP 29

FRAMINGHAM, MA The Framingham ARA will hold its Fall Flea Market and Exams at Framingham H.S. on A St. Setup at 8 AM, general admission 9 AM–1 PM. To reserve tables, call *Martin Bayes AA1ON at (508) 435-0564,* and send check payable to *FARA*, to *FARA, P.O. Box 3005, Framingham MA 01701*. To register for exams, send a check for $6.05, payable to *ARRL/VEC*, to *Dick Marshall WA1KUG, 37 Lyman Rd., Framingham MA 01701*. Walk-ins will not be accepted after 10 AM. Talk-in on 147.15(+) Rptr.

YONKERS, NY A Giant Electronic Flea Market will be presented by the Metro 70 cm. Network, 9 AM–3 PM (rain or shine) at Lincoln H.S. on Kneeland Ave. Indoor Flea Market only. New and used equip. for CB operators, amateur radio operators, commercial 2-way radios, computers, stereo buffs, electronic parts and kits and much more will be on sale. VE Exams. Table setups at 7 AM. For registration call *Otto Supliski WB2SLQ, (914) 969-1053*. Talk-in on 449.425 MHz PL 156.7; 223.760 mHz PL 67.0; 146.910 Hz; and 443.350 MHz PL 156.7. Mail paid reservations to *Metro 70 CM Network, 53 Hayward St., Yonker NY 10704.*

OCT 4–5

OTTAWA, CANADA Chapter 70 will host the 1996 QCWA Internat'l Convention at the Citadel Inn at 101 Lyon St. in Ottawa. Many events are being offered to attendees. Queries may be made via *Internet: boØ75@freenet.carleton.ca. Packet: VE3GFI@VE3FD.#eon.on.can.noam*, or *telephone (613) 826-2426*. Advance reg. must be received by Sept. 16th.

OCT 5

TEMPLE, TX "Ham Expo," a Tailgate Swapfest, plus commercial vendors, will be held 7 AM–3 PM at Bell County Expo Center, Belton TX. There will be a T-Hunt at 9 AM. VE Exams for all classes starting at 1 PM. Tailgaters setup Sat., Oct. 5th at 6 AM. Commercial vendors may set up Fri., Oct. 4th, 5 PM–10 PM. There is a $10 table surcharge for early setup. Talk-in on 146.820(-) PL 123, and 147.300(-). Contact *Mike LeFan WA5EQQ, (817) 773-3590;* or *E-mail mlefan@vvm.com.*

OCT 6

SPRINGFIELD, OH The Independent Radio Assn. of Springfield will hold its annual Hamfest at the Clark County Fairgrounds, located 1/4 mi. north of Interstate 70 (exit 59) and State Route 41. The event will be open 8 AM–3 PM. For details, call *Jerry KB8FMW, (513) 568-4070*. Talk-in on 145.45(-). For reservations call *Bernie NBXKF, 9 AM–6 PM, at (513) 882-6559;* or *Bill N8XIW, 7 PM–10 PM, at (513) 324-4082.*

SPECIAL EVENT STATIONS

AUG 24–25

PETERSBURG, NE The Albion ARC will use vintage radios and equip. to operate Station KBØTLX 1800 Aug. 24th–1800 Aug. 25th to help celebrate the Nebraska State Antique Tractor and Horse Plowing Contest. Freqs.: 7.240, 14.240, 21.130 and 28.330. To receive a special QSL card, send name, address, and QSL to *Steve Wright KAØVEU, 929 Park, Albion NE 68620 USA.*

AUG 31–SEP 2

NUTLEY, NJ The Robert **D**. Grant United Labor ARA will operate KB2YCT, the Club station, along with other stations around the country, to honor the working men and women of this great nation. Connect on the General portion of 40m, 20m, 15m, and 28.420 phone-in on the Novice phone band. For a certificate, send an *SASE to station's call* and *P.O. Box 716, Nutley NJ 07110-0716 USA.*

SEP 9–14

LINWOOD, NJ Southern Counties ARA will operate K2BR Sept. 9th to Sept. 14th, from the Miss America Pageant in Atlantic City NJ. (IOTA: NA 111 - Absecon Island) Freqs.: Phone—25 kHz inside lower General class band edge. CW—65 kHz inside lower General class band edge. Novice—28.100–28.500 kHz. QSL with a #10 SASE via *SCARA, P.O. Box 121, Linwood NJ 08221 USA.*

SEP 14

EFFINGHAM, IL Effingham County, EM59. The Nat'l. Trail **ARC** will operate K9UXZ in conjunction with the annual Transportation Festival, 1 PM–8 PM CDT. Operation will be on lower General and Novice 10 meters. For a certificate and/or QSL card, SASE to *K9UXZ, Nat'l. Trail ARC, P.O. Box 903, Effingham IL 62401 USA.*

SEP 16

DANVILLE, PA Liberty-Valley Elementary School will operate KC3HP, WC3A, N3IRN, and N3LQS on the General portion of the 15m, 20m, 40m, and 75m bands, from 1300Z–1900Z. For a certificate, send QSL to *D. Miguelez N3POB, Liberty-Valley School, 175 Liberty-Valley Rd., Danville PA 17821 USA.*

SEP 19–22

LEAVENWORTH, WA Ham radio operators will operate a Special Event Station during Salmon Festival 96 using the special prefix W7F. Operation will be from the fish hatchery located at Leavenworth. Sep. 19 & 20 will be for area schools to talk with out-of-area schools. There will be contact only with ham school stations on these two days. The station will make contact with hams on the 21st & 22nd on 20m (14.252), 40m (7.252), and 75m (3855) bands. Certificates will be issued to stations contacted. Mail your QSL card to *FISH, General Delivery, Leavenworth WA 98826 USA*. All entries must be post marked before Oct. 1, 1996. There will be a prize drawing held on Sat., Oct. 5th.

SEP 28–29

CAPE COD, MA WB1U will operate 1400Z Sep. 28th–2100Z Sep. 29th, to commemorate Marconi Station's 95th Anniversary. Operation will be in the General portions of 15, 20, 40, and Novice portions of 10 and 80 meters (CW and SSB). For a certificate, send an SASE to *Ray Hilson, 6 Sherman Place, Norwalk CT 06851 USA.*

NEVER SAY DIE

Continued from page 77

legally end our old music business companies. This doesn't affect *73*, other than it'll give me more time to get on the air and have some fun and to pursue my work with cold fusion. I enjoyed the music business, but "I've been there, done that." Ten years was more than enough.

I was not surprised by the recent class action suit against the six major music companies (five are foreign-owned) for price fixing. But then the whole industry is corrupt, as I've discussed in my past editorials. The big winners are the six majors and big record store chains. The big losers are 98% of the performers, 100% of the independent record companies, and 100% of the independent record stores. Capitalism works fine until companies get big enough or work in secret groups to control distribution and prices. Lobbyist payments to Congress keeps the Feds at bay. I've testified at Congressional hearings where it was quite clear that the committee chairman was safely in the music industry's pocket. The industry people, whom I knew well, laughed about it.

The majors were candid. They hated the impact I was having in my efforts to build the market share for independent record companies, but my *CD Review* was selling about $30 million of

Heathkit Mania

And all bought at bargain prices!

Shane P. Brady WB2WPM
34 Rosewood Drive
West Seneca NY 14224

I earned my Novice license 22 years ago, after seeing a ham radio demonstration as a Boy Scout some 10 years earlier. Recently married and unable to afford new equipment, when I heard that a local ham was selling a Heathkit SB-102, I went for it. That SB-102 and a 40 meter dipole were my introduction to actual QSOs.

I remember looking through the Heathkit catalogs, trying to imagine a station with all the matching accessories for my SB-102. The XYL got me started by giving me the matching SB-630 station console for Christmas. This had a 24-hour digital clock, a phone patch, an SWR meter, and a 10-minute timer, all in one. I then added the matching SB-600 station speaker. Not a shabby-looking station for a Novice in 1974. The SB-102 is a 13-tube HF SSB/CW transceiver, rated at 180 watts input—80 watts more than most of today's radios—running a pair of 6146Bs as finals.

When I upgraded to Advanced, the SB-102 got me contacts with UA, ZS, VK, and XX. I added the optional 400 Hz filter for CW, and what a difference that filter made!

Sure, I sold the SB-102 and went on to a solid-state synthesized radio with 100 memories and computer-controlled microprocessors, but I couldn't forget my vision: to have a complete line of Heathkit radios and accessories.

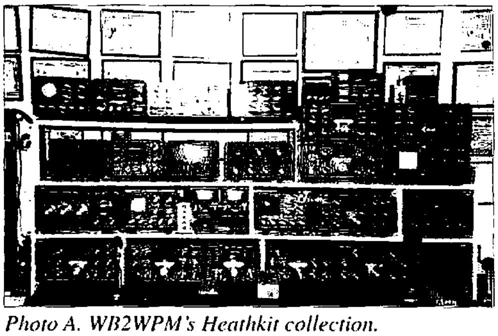

Photo A. WB2WPM's Heathkit collection.

Building the dream

Several years ago I heard about a retired ham with some old gear to sell. That visit changed my shopping habits at hamfests. There was an SB-102 and an SB-200 1 kW amplifier. The SB-200 is still an extremely popular 1 kW amplifier. It uses a pair of 572B tubes in parallel for finals. Together, the SB-102 and the SB-200 were a popular combination in the late '60s and early '70s. We worked out a great deal; he just wanted them to go to a good home and was not interested in the dollars.

> *"So what do I do with all of this outdated equipment? I have fun with it!"*

Clearing a spot on a side table, I made a new home for my old friends. I had kept my SB-600 speaker and SB-630 console; these too joined the new family.

As a Novice in the early '70s, it seemed to me that four out of five QSOs were with hams who had Heathkit equipment. Now, in the 1990s, I was trying to make contacts like I did 20 years ago, with so-called obsolete equipment.

Does that Heathkit combination still work? You bet it does! No, it doesn't have the 100 memories, and I do have to wait a couple of minutes for the tubes to heat up. But what it does very well is make contacts. You're not going to hear signals coming in at less than 0.1 µV on a crowded band, but how often are you really under those conditions? Remember, a clean signal from 20 years ago still sounds the same as a clean signal from a state-of-the-art transmitter today.

Finding the pieces

At a local ham auction, I ran across an SB-610 monitor scope which also matched the famous Heathkit "SB green line" of equipment. Now I had five matching pieces from the SB line. The station was starting to look like the Heathkit catalogs of 20 years ago. I was hooked. I had to have *all* the pieces to the Heathkit SB line!

Packet radio is a nice way to find "wanted" equipment, and I've had great success finding bargains for older equipment. A couple of messages out on packet and soon I had added the SB-650 digital (nixie-tubes) frequency display and the SB-620 spectrum analyzer, for under $25 each. Yes, they both worked when I plugged them in. Another packet request and I had two SB-500 2 meter transverters added to my collection (at next-to-nothing prices). The SB-500 also uses 6146 finals for 50 watts output for SSB and CW.

The next piece took some ads in the ham classifieds. I had only seen one SB-640 in my life, and that was years ago at Dayton. The SB-640 is a remote VFO that interfaces with the SB line of transceivers for working split frequency.

The hardest piece to locate was the SB-110 6 meter transceiver. Most people hang on to these '60s vintage rigs, which use 6146 tubes for finals for 180 watts PEP on SSB and 150 watts CW.

Hamfests will yield a bumper crop of old tube-type Heath equipment. I've purchased complete working HF rigs for $20!

I've since added the SB-300 and SB-303 receivers, along with their

Photo B. WB2WPM at his station. *Photos by WB2JFP*

matching SB-400 and SB-401 transmitters, to the collection. These twins were known as the "poor-man's Collins." HW-100s and HW-101s have joined the family as well, along with many green accessories such as wattmeters, phone patches, keyers, and SWR bridges.

No, not everything works when I get it, but in most cases all that is required is replacing a tube or two and a quick tune-up. At hamfests there are always boxes of tubes for sale. The average price for a tube is $2, but many times they can be found for only $1.

Manuals are worth their weight in gold when working on this older equipment. I make copies of all manuals and store them away. I'm even collecting manuals for equipment I don't have yet, just in case I come across it someday. With the manuals, tune-ups are a cinch, as in most cases all you need is a known frequency source and a VOM. Heathkit's famous step-by-step instructions will lead you through complete tune-ups, if need be.

Naturally, I've added Heath's last line of SB equipment to my collection. At another operating position, sits the all-solid-state SB-104A transceiver and its matching SB-604 speaker and power supply, the SB-614 monitor scope, and the SB-634 station console and its matching SB-644A remote VFO. All working, and all obtained at bargain prices.

So what do I do with all of this outdated equipment? I have fun with it! When visitors come to the shack, most are in awe of all those dials and gleaming knobs. It's almost a shame to tell them that, averaged out, I have less than $35 per piece invested in this sub-hobby. That's less than a used state-of-the-art rig!

Am I finished with my collecting? No way. There is still an SB-313 shortwave receiver out there waiting for me, the last piece I'm missing for my collection! Besides, I still need more basket cases to combine with other basket cases, to come up with working units. Why do I need more and what am I going to do with all of these Heathkit radios? Funny, that's what N2INY, my XYL, asks.

"When visitors come to the shack, most are in awe of all those dials and gleaming knobs."

Things That Go "Woof"

This month, we're going to take a look at the kinds of problems that give service technicians nightmares; the ones which keep the antacid business booming. I'm talking about "tough dogs," those unusual repair problems that, in the long run, aren't unusual enough! Here are a few I recently ran into and solved.

Yes and no

This one was a 2 meter HT that wouldn't transmit—sometimes. Sometimes it would work just fine, but then I'd press the PTT again and the transmit light would just flash for a fraction of a second and go out, resulting in no RF output. Receive was fine. Bad connection, right? I couldn't find one, and wiggling and tapping things had no effect. Once it started transmitting, it would continue for as long as the PTT was held down, but the next attempt might or might not work.

This baby was pretty much screaming "woof! woof!" but I was determined to figure it out. I poked, prodded and couldn't get anywhere. The mystery finally started to unravel, though, when I noticed that the problem only showed up when the radio was in simplex mode; using an offset in either direction made the transmitter work fine every time. Now I was getting somewhere! It had to be in the offset switch, I figured. I checked the switch, and even jumped it just to be sure, but it made no difference. I put the radio down on the bench and pondered that one for a while. OK, I had localized the problem, but what the heck could it be?

Localized ... hmmm, that had to be it! This was a pre-microprocessor radio. What difference could that make? Well, in a micro-controlled rig, offsets are selected in software; the radio simply retunes to the transmit frequency every time you press the PTT. Before micros, though, that was impossible, necessitating another approach: There were three crystals, one for each offset (up 600 kHz, down 600 kHz, and simplex), that set the frequency of a local oscillator which was then mixed with the synthesized one you set with the thumbwheel controls. That way, the circuitry and crystal-generated frequencies required to create the offset were the same, no matter what frequency you selected for operation. (That's also why non-standard offsets weren't available, as separate crystals would have been required for each of them.)

It was the word "localized" that set me thinking in that direction. Of course, an unreliable simplex offset crystal would cause all these weird symptoms. The transmit light would go out because the synthesizer would detect that the final mixed frequency was not there.

Sure enough, that was the problem. Of course, it could have been a capacitor or something else easily obtainable, but any tech can tell you that the part that needs replacing is always the hardest part to get! Furthermore, failing crystals often act just this way. Their activity level goes down, so sometimes they'll start up and sometimes they won't. A quick blast on the crystal with the freezing spray made the rig work every time, until the crystal got back up near room temperature, at which point it got "temperature-amental" again. Case solved. Another tough dog muzzled.

El Zappo

This one was a three-tube HF linear amplifier that used 8874 tubes, which are small high-power metal-ceramic types. The amp was used, and had just been shipped here. It had a serious problem: Turning it on blew its fuses almost instantly, even though the shipper swore it had worked just fine when it left! "Hard shorts" like this can be difficult to diagnose, mostly because you can't put power on the circuitry to see what's going on. As soon as you do, it blows the fuses again, and you're left with a dead circuit.

This amp used step-start protection. That is, it avoided serious inrush current to the massive power transformer by first putting all the current through a couple of resistors, and then bypassing them a moment later with a relay. The first thing I wondered was whether the power transformer had a short. That's tough to know, because the DC resistance of the windings in such a big beast is pretty low to begin with, making simple ohmmeter measurement worthless. The windings read close to zero ohms on a good transformer anyway, so there's no way to tell. I suspected, though, that the transformer was good, for three reasons: First, they almost never go bad. Second, the step-start resistors weren't fried, suggesting that the problem was on the other side of the transformer and didn't kick in until full power was applied. Finally, the meter lights came on for a fraction of a second before the fuse blew. That told me that the primary probably had to be OK, or there wouldn't have been any power at all. Of course, there still could have been a short in the high-voltage winding (which is where I'd most expect to find it).

I went around and around on this one for one or two hours, on the assumption that the transformer had no shorts. The high-voltage diodes and capacitors were all OK, and I couldn't find any shorts anywhere else, either. What the heck was shorting out and taking all that current? Could it be a shorted tube? I checked from anode to ground with my ohmmeter, but they all read open, as they should.

A quick call to the manufacturer exposed my hasty mistake. They suggested I disconnect the anode caps from all the tubes and try turning the amp on. That did it! I fired it up and it worked normally, with the correct high voltage shown on the meter. So, it was a tube after all! Turns out this kind of tube failure is common after shipment. I guess those tubes are more fragile than I'd realized. Apparently, physical shock can cause internal elements to shift just enough so they'll short out when the tube is warmed by the filament and high voltage is applied. So, they look good on an ohmmeter, but they aren't. Putting the caps back on, one at a time, exposed the bad tube. Another weird one solved, though I can't take credit for it. Woof!

> ***"I'd heard of such a thing happening in various kinds of picture tubes, but had never actually seen it."***

Déjà vu all over again

I should have recognized this problem, because I'd seen it before, albeit under very different circumstances. I have a projection TV set that came to me with similar trouble. It would turn on, but the red tube would glow so brightly it practically lit up the room, and the other two tubes barely ran at all. Of course, I couldn't leave it on long enough to work on the set because it would have destroyed the red tube. Projection tubes are about as expensive as transmitting tubes, and much harder to replace: it wouldn't have been worth keeping the set if I'd had to get a new tube.

After going over all the CRT circuitry in the red section and finding it to be the same as that in the other two (identical) sections, I concluded it had to be a short in the tube. I'd heard of such a thing happening in various kinds of picture tubes, but had never actually seen it. So, out came the old ohmmeter, but there was no short to be found; the elements all read open, as they should. Then, I had an idea. Perhaps it was a thermal short, just as I described in the linear amplifier story. I turned the set on, let it run for about 30 seconds, and then pulled the plug and yanked off the CRT socket on the red tube. Naturally, I wore

rubber gloves, because I wanted to live long enough to enjoy watching the set. I quickly measured between the filament and cathode, which were the closest two elements and the ones most subject to this sort of trouble. And there it was: My meter showed a short whose resistance quickly began to rise as the tube cooled off. Within a few seconds, it was gone! I'd found it: now, what could I do about it?

Unlike with transmitting tubes, this type of short can be circumvented in CRTs. All you have to do is isolate the filament, using a 6.3-volt filament transformer. That way, the tube is still shorted, but the short leads nowhere. The fix worked fine, and the set is still going strong. Woof, woof!

Well, I'm dog tired just from thinking about all these tough dogs! Over the years, I've struggled with countless woofers, and I've probably learned more from them than from anything else. Naturally, nobody enjoys tough dogs, but they're out there, and I promise you'll see your share if you keep working on electronic things. I also promise you'll learn a lot.

Until next time, 73 de KB1UM.

CDs a month, so they *had* to advertise. During this time the indie market share went from 4% to 14%, a gain of several billion dollars in sales.

I love music, but I didn't want to spend the rest of my life reviewing new CD releases and giving talks at music industry conferences all around the world.

LETTERS

Continued from page 6

American hams or organizations have the right to unilaterally impose a "Morse Forever" policy on the international community; besides, wouldn't it be nice to have more DX stations to talk to? If Americans truly feel the "Morse filter" works, they would be free to pursue it on a local basis; and if they later changed their mind, they would not be able to blame it on the "international treaty problem."

None of this is meant to diminish the accomplishments of the radio pioneers; CW needs an appropriate shrine next to spark and AM. You can argue in favor of a question or two on spark transmission techniques on the test. In a real emergency, I would not hesitate to kludge a spark rig for a distress call; somehow I find it hard to imagine anyone modifying a modern IC-filled broadcast receiver in an emergency environment for practical use as a transmitter. But this letter is about current and evolving practice, and so I offer the following reality checks :

1. The Coast Guard no longer monitors Morse transmissions.

2. The armed forces no longer need Morse operators.

3. The merchant marine use of Morse is vanishing.

4. The Boy Scouts have dropped the Morse merit badge.

5. The "Morse filter" doesn't work. Check the high ends of 75 and 20 meters or "2 meter CB" in any major metropolitan area. Check how many coded licensees have actions to revoke their license as compared to "those codeless Techs." Our ARRL affiliated club could not function without the new codeless members.

6. The path of choice into the hobby is no-code. About a third of US hams are codeless. Tragically, the hobby is stagnating in growth, primarily due to the Morse requirement for frequencies below 30 MHz. This does not bode well for hams or the hobby in general, or organizations or businesses who derive their income from a healthy, young, ham radio environment.

7. It is very difficult to interest young people enough to jump the Morse hurdle, because it is an obsolete technology. Our club has been in three schools trying to start up clubs. For less money, a young person can learn a marketable job skill, gain access to useful academic information, and meet a wide range of interesting people on the Internet. If we thoughtfully consider the declining ability of our nation as a whole to compete internationally, wouldn't it be helpful to "grow" some technically savvy youngsters?

8. The ARRL has dropped the Novice Roundup (a CW contest for beginners).

For these and other reasons, I believe that no rational argument remains to retain the Morse code as an entry requirement at all. However, if the requirement remains in the ITU treaty, it is my strong feeling that the hobby would be best served by reducing the code requirements for most license classes in the US to a token recognition exam with no speed requirement at all, since that satisfies the "letter of the law." The few remaining "Morse Forever" diehards can still hang out at the low end of the band with their side-swipes, with no harm done. Don't get me wrong, I spend a lot of the limited operating time I have down there. But the choice was clear this year—buy myself a nice new rice box, or get my son the new P100 computer to succeed in school. I really worry because I find a lot of the guys I used to talk to frequently are not even on 2m, but at their keyboards. I urge all hams, the ARRL, the QCWA, and the IARU to do the right thing ... before it is too late.

There is a second important issue that should be taken up at the next WRC ('99). Forty meters, particularly in the northeast, north central, and eastern seaboard of the US after 3 p.m. local time is virtually useless for ham communication. The incursion of powerful foreign shortwave broadcasters, intentionally beaming their programs to North America in violation of agreements, is so pervasive that prosecuting any deliberate jamming of hams by hams is insignificant by comparison. The mess on 40 drives people down to the overcrowded 75m band, exacerbating the problems there. The time for dispassionate negotiation has past. This has been a problem since my entry into the hobby in 1960. As a Novice, I played by the rules and took my precious crystal apart and ground it with a slurry of Bab-O™ cleanser to get out from under the foreign BC. I suspect my friend was more rational; he didn't waste any more money on "rocks"—he built a VFO kit and used it illegally as a Novice (another example of regulations lagging far behind the state of the art).

I propose the following possible scenarios, individually or in combination:

1. Eliminate all amateur power restrictions on 7.15-7.3 MHz. This would provide those with the inclination an opportunity to gain experience constructing and operating some "world class" transmitting equipment. FCC type acceptance would prohibit band switches in commercial units at the 1.5 kW to 100 kW or higher power levels. American commercial manufacturers could turn a tidy profit with little foreign competition. Day/night restrictions, as on the old shared 160m band, could be imposed. If it creates massive QRM in Europe, tough noogies—two can play that game. This proposal is meant seriously, not in jest.

2. There is mandatory use of "split frequency" operation to work DX on 40 phone. This is simple waste of precious spectrum space. Also, the bandwidth restrictions of a compact beam rarely permit optimum performance on frequencies that are separated that far apart. Encouraging the use of optimum directive antennas would reduce interference in at least some directions. Some realignment, at least for upper-class licenses, with the international allocations seems the only sensible solution. To reduce complaints from DX operators, limit power in that segment to the same level they have: 300-400 W. It is probably heresy to suggest we extend that limit to all frequencies, as a matter of fairness. Also, it's impossible to

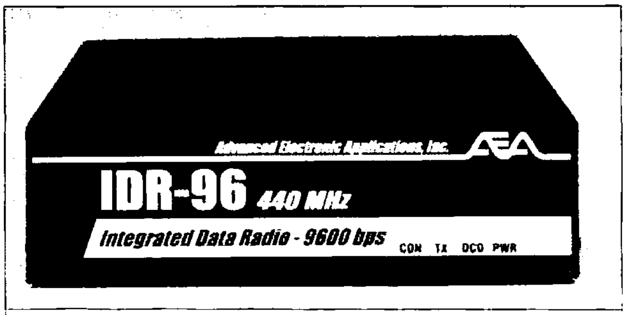
New Products



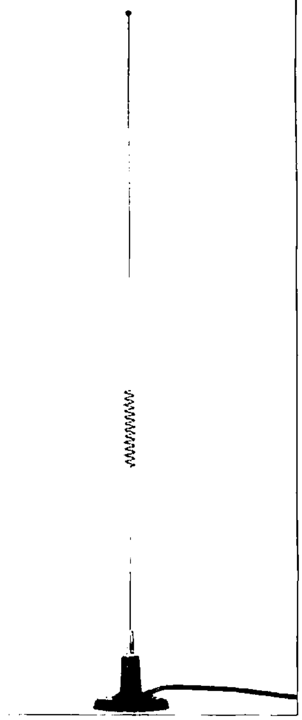
Plug and Play Packet

Advanced Electronic Applications, Inc. (AEA) has the next progression in Packet Radio—an integrated Data Radio called the IDR-96. It integrates the proven technology of the PK-96 TNC with the simplicity and high switch-over speed of a crystal-controlled radio.

The IDR-96 is a 9600 bps TNC with the features Packet users demand: full-featured mailbox; Gateway node operation; advanced Global Positioning System commands; identification of TCP/IP, TheNet, and NetROM stations; and more, for a suggested list price of $499.

The integrated radio is built into the unit, so you avoid the connection and compatibility problems associated with 9600 bps Packet; and two software programs are included with every IDR-96: PC PakRatt Lite™ and APRS™. See your dealer for best price and availability. Call AEA's Literature Request Line at (800) 432-8873 for more information on all AEA products.

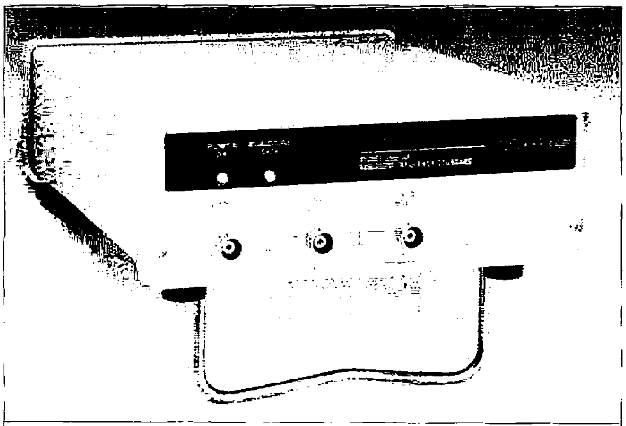
MFJ-1729 *Super*Gain™*



A powerful dual-band magnet mount antenna for ham radio is available from MFJ for only $29.95!

The MFJ-1729 *Super*Gain™* gives you 6.3 dB on 440 MHz and 2.6 dB on 2 meters—the perfect choice for dual-band mobiles and handhelds. MFJ's exclusive 29 3/4-inch stainless steel *SlimLineRadiator™* minimizes wind vibration for less SWR flutter, and besides the working advantages of the MFJ-1729, the thing just looks great! It's sleek, stylish, and the base has a pad to prevent scratches on your vehicle. Of course it comes with MFJ's *NO MATTER WHAT* one-year unconditional warranty.

For more information, contact your dealer or MFJ Enterprises, Inc., P.O. Box 494, Mississippi State MS 39762. Phone (601) 323-589, FAX (601) 323-6551, or order toll-free (800) 647-1800.



Put This on Your Wish List

The Model 2950AR Atomic Resonance Rubidium Frequency Standard from Novatech Instruments, Inc. has simultaneous sinewave outputs of 10 MHz, 1 MHz, and 100 kHz, and at $3,950.00, it's the lowest priced laboratory-type Rubidium Standard on the market. The 2950AR is ideal for use as a master oscillator in labs and ground stations as well as for tests and calibration. For more information, contact: Novatech Instruments, Inc., 1530 Eastlake Avenue E. - Suite 303, Seattle WA 98102. Call (206) 322-1562, FAX (206) 328-6904, or view the complete data sheet on their Website at http://www.eskimo.com/~ntsales.

More Power!

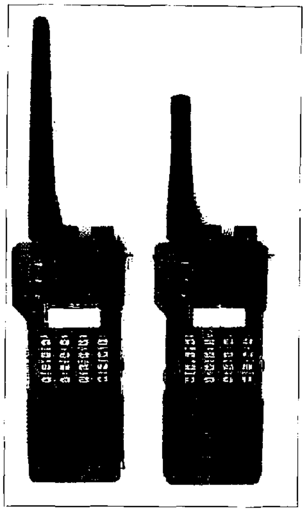
Get 50% more power on 2m and 75% more on 440 MHz than the nearest competitor offers—for $60, less! Mirage Communications Equipment BD-35 is capable of boosting your power to new levels: it features auto-band selection, single connector for dual-band radios/antennas, full duplex operation, reverse polarity protection and much, much more.

This nifty compact amplifier works with all FM handhelds up to 7 watts. You get 45 watts capability on 2m and 35 watts capability on 440 MHz, and Mirage's exclusive *FullDuplexAmp™*, which lets you talk on one band and listen on the other, just like a telephone conversation. The custom wraparound heatsink gives you excellent heat distribution and the reverse polarity protection will save your amp if you accidentally connect the power backward. A free mobile mounting bracket is included, and you get Mirage's legendary ruggedness and a full one year warranty—all for $199!

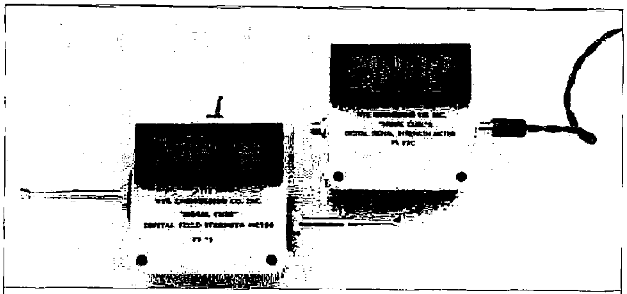
Call your dealer or Mirage Communications at (800) 647-1800 to find the dealer nearest you.

Handies are Dandies

Premier Communications has a couple of winners here, in the AT-200/2 meter and the AT-400/70 cm FM handheld transceivers. Both are equipped with easy-dial VFO, 20 memories, backlit display and DTMF keypad, 4 scan modes, dual watch and call channel. They've also got 38 tone CTCSS encoders and decoders, and DTMF paging for silent monitoring, along with lots of other goodies, but Premier emphasizes their simplicity of operation and solid reliability, something everybody looks for in a handheld. A full line of mating accessories is available.



For more information, contact Premier Communications, 20277 Valley Blvd., Walnut CA 91789; telephone (800) 666-2654; FAX (909) 869-5710.



Signal Cube® from Nye Engineering

Here's a unique little gem from Nye—a 2.5" cube unit designed as a digital repeater of the receiver's S-meter. It connects to the terminals of the receiver's analog S-meter and is powered by a built-in 9V battery. The battery will supply the unit continuously, when the on/off switch is left on, for two months. The unit can be used with hundreds of feet of cable, if required.

The digital readings are in S units 0 through 9 and in dB above S9 to 40 dB, exactly following the analog S-meter. The Signal Cube, with its half-inch digits and high resolution, is much easier to read than the regular analog S-meter.

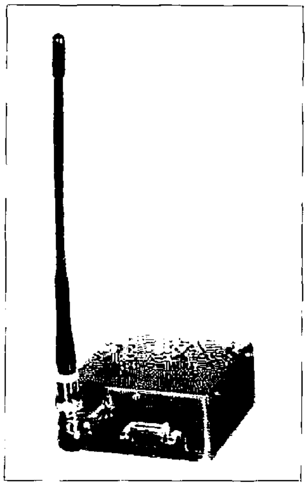
The Signal Cube is available for $189 from Nye Engineering Co. Inc., 4020 Galt Ocean Dr., Suite 606, Fort Lauderdale FL 33308. Phone (954) 566-3997 or FAX (954) 537-3534.

Xtal Set History

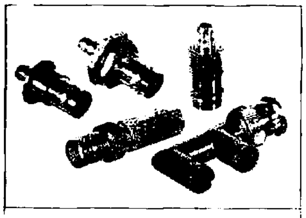
"Crystal Radio: History, Fundamentals, and Design" is a new book from the Xtal Set Society, Box 3026, St. Louis MO 63130. This 124-page, $11 paperback chronicles the history of the crystal detector. It also covers basics such as antennas, lightning protection, grounding, tuned circuits, multi-tuned circuits, wave traps, and detection. Xtal set fans will probably also want to subscribe to the Society's ($10 per year) newsletter.

Neulink 9600 Is Now a Repeater

RF Neulink is now shipping its Neulink 9600 with repeater capability, a no-cost option available in all production transceiver modems. Neulink 9600 is a high-speed, 57.4 Kbps, 9.6 Kbps over-the-air, 2 watt transceiver modem. With its 65,000 unique ID codes, this synthesized UHF modem is capable of point to point and point to multipoint networking. It is an intelligent modem that has the capability to call up the entire network, group calling, or any individual remote in the system. Protocol is full handshake and includes RTS, CTS, DSR and DCD as well as error detection and correction.



For more information, contact RF Industries, Neulink Division, 7610 Miramar Road, San Diego CA 92126-4202. Telephone (800) 233-1728, FAX (619) 549-6345, or E-mail: 102061.2261@compuserve.com.



New 75Ω Connectors

RF Connectors, a division of RF Industries, introduces its new line of 75 ohm connectors.

This series of coaxial connectors include 75 ohm BNC adapters and cable connectors. These connectors are available with both nickel and silver plating, Delrin and Teflon dielectric and all feature gold-plated captivated center contacts.

These new connectors are available from RF Connector Distributors throughout the US, Canada and Mexico. For a complete listing of 75 ohm adapters and connectors, product specifications and availability, call (800) 233-1728 or E-mail: 102061.2261@compuserve.com.

Radio Bookshop

Great ARRL Books!

AR1996 **The ARRL 1996 Handbook** includes the latest innovations in ham radio, plus all the fundamental data. $38.00

AR1086-4 **ARRL Operating Manual** Information on how to make the best use of your station, including interfacing with home computers, OSCAR, UHF-VHF. $18.00

AR4173 **Now You're Talking! All You Need To Get Your First Ham Radio License**–A complete study guide for the Technician and Novice written exam. Practical information every beginner needs is written clearly and simply and in small doses. $19.00

AR4734 **ARRL Antenna Book**. Best and most highly regarded info on antenna fundamentals, transmission lines, design, and construction of wire antennas. $30.00

AR4971 **ARRL Repeater Directory 1995-1996** Over 19,000 listings with digipeaters, handplans, CTCSS(PL(TM)) tone chart, frequency coordinators, ARRL special service clubs, and beacon listings from 14MHz to 24GHz. $7.00

AR0402 **Solid State Design** Good basic information, circuit designs and applications; descriptions of receivers, transmitters, power supplies, and test equipment $15.00

AR3177 **ARRL Spread Spectrum Source Book** From a deceptively simple beginning, a group of experimenters set out to develop first theoretical and later practical systems for spread spectrum communications. This book consists of articles, papers and government reports that document the process whereby amateur spread spectrum progressed from the drawing board to the airwaves. $20.00

AR4661 **ARRL's Antennas & Techniques for Low-Baud DXing** can be your ticket to low-band success. $20.00

AR3851 **Hints and Kinks** Ideas for setting up your gear for comfortable efficient operation. $10.00

AR3185 **The Satellite Experimenter's Handbook** by Martin Davidoff K2UBC Expanded and revised. Focusing on satellites built by and for the international radio amateur community $20.00

AR4645 **Satellite Anthology** The latest information on OSCARs 9 thru 13 as well as the RS satellites, the use of digital modes, tracking antennas, RUDAK microcomputer, and more! $10.00

Radio Bookshop

Phone 800-274-7373 or 603-924-0058. FAX 603-924-8613. or see order form on page 88 for ordering information.

The Last Skeptic of Science by René. We all know there have been a bunch of ice ages, right? Wrongo, says René! And that the moon causes the tides. That volcanoes are caused by magma leaking from the earth's core. That the transmutation of elements is difficult. That the earth, with it's iron core is a big magnet. Plus a bunch of other blasphemies, which René disproves most convincingly. Heck, we all know that two materials of different weight will fall at the same speed in a vacuum. Galileo proved that once and for all. Could Galileo have been wrong? You betcha. René spins out one after another of thoroughly accepted scientific truths and slays them. Boy, will you have things to talk about after reading this baby! 179p, 81/2 x 11. Order **SK** $25 from Radio Bookshop.

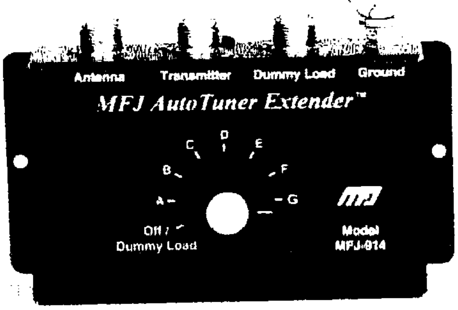
NASA Mooned America by René. The proposition that the Apollo flights were all faked and NASA never got anyone to the moon is patently ridiculous. I'm still waiting to hear from anyone who has read this book and still believes the moon landings weren't the biggest hoax in history. René has done his homework thoroughly and cites 30 darned good reasons why he thinks we've all been lied to. 176p, 8 1/2 x 11. Order **NA** $25 from Radio Bookshop.

Cold Fusion. Look, you ignored my blandishments to get involved with repeaters, which would have led you into getting rich via cellular telephones. Then you ignored my pleas to get involved with personal computers. So you're not a Bill Gates, Paul Allen, or Steve Jobs. You can't say I didn't try. The next biggie is going to be cold fusion. You can get an Overview report on the subject for $2 (order **CFO**) from Radio Bookshop. Or you can jump in and subscribe for 12 issues. The special *73* subscriber rate is $75 instead of $98. Warning, some of the articles are technical, some are on experimental systems. Order **CF-sub** from Radio Bookshop. Motorola and Bechtel are already jumping in on this new technology, yet the leading American researcher in the field had his lab in his garage and had less than $5,000 invested. He's now working for Clean Energy Technology Inc. (CETI).

The Book List by Wayne Green. This is a list of 83 books that I say you are absolutely crazy if you don't read. And none of this "I don't have time to read" crapola. These books are the best books I've found in a whole bunch of fields. Many were recommended by readers as being top notch. It's time to become educated on health matters, our school system, our corrupt government, history, science, communicating with plants and animals, child development, the occult, and so on. Order **BL** $5 from Radio Bookshop.

AIDS Cure. Can a simple $19 electrical (for the parts) gadget you should be able to build in an hour cure the dread "incurable" AIDS virus? Plus clean out any other virus, microbe, yeast, parasite, or fungus in the blood? This approach was discovered by the Albert Einstein College of Medicine and then kept secret. The medical industry's worst nightmare is a cheap cure for expensive diseases. Are tens of thousands of people dying unnecessarily? This has the original Beck device, plus a reprint of the May *73* Miller unit. Can this even cause a weight loss for fatties? And can the magnetic pulse unit used to zap the HIV virus out of lymph glands be used to regrow male pattern baldness? Order **AIDS** $10 from Radio Bookshop.

More New Products



MFJ-914 *AutoTunerExtender™*

Now you can match nearly any antenna automatically! The MFJ-914 is a heavy-duty wide-range impedance transforming device, carefully designed for the flattest frequency response and the lowest loss—it will transform your antenna impedance up or down by as much as ten times, and it's only $59.95!

Extremely easy to use, the MFJ-914 can be used with any transceiver from 160 through ten meters at up to 300 watts. It connects between your transmitter and antenna with supplied SO-239 connectors—just bypass your transmitter's auto tuner and adjust the knobs on the MFJ-914.

For more information or to order, contact your dealer or MFJ Enterprises, Inc., P.O. Box 494, Mississippi State MS 39762 or call (601) 323-5869, or (800) 647-1800; or FAX (601) 323-6551.

Tape-Jay™ Stealth 2m J-Pole from HAMCO

HAMCO, an acronym for *Hidden Antenna Manufacturing Company*, is living up to the name with a new concealed antenna for 2-meter FM aficionados. *Tape-Jay* is just the ticket to get the HT and base units into the repeater from fringe areas. It is made from 3.5 mil sticky-back copper foil, and will adhere to almost any household material—windows, walls, chimneys, or even fabric, to make a portable roll-up J-Pole.

The easy-to-assemble kit comes with pre-cut elements, coax connector, cable clips and clear assembly instructions. No soldering, no special tools required. It's strong, durable, usable indoors or out, and like all HAMCO *TapeTenna™* products, you can paint it to match your mounting surface and render it virtually invisible! Order for $19 plus $4 S&H by check or money order from HAMCO, Dept. A3, P.O. Box 25, Woodland Park CO 80866.

September promises to be a good month for HF band propagation. Seasonal conditions are improving and, hopefully, solar flux will begin to rise again after a long period of 60s and 70s, although sunspot minimum has barely passed.

The only Poor (P) times this month surround the 14th and 27th, with possible atmospheric as well as ionospheric disturbances. As we're well aware, this is still hurricane season, so keep a sharp lookout for the possibility of tropical storms on or near these two days.

The week of the 6th to the 13th is likely to be the best week during the month, with Good (G) conditions on the HF bands. The remainder of the days are expected to be Fair or trending, as you can see from the calendar.

29 F-G	30 G					

10-12 meters

Generally Poor, except for occasional transequatorial propagation with F2 openings on the best days—most likely South and Central America.

15-17 meters

DX to Africa and Latin America on the Good days possible, with short-skip out to about 1,000 miles or so in the U.S.

20 meters

Your best band for DX openings around the world from dawn to dark, and openings to the Southern Hemisphere after dark in evening hours. You can expect excellent short-skip during the daytime to 2,500 miles or so.

30-40 meters

These bands ought to be open for DX from just before sunset to just after sunrise. Signals from the east should peak until midnight, and after midnight to other areas. Daylight short-skip of about 500 miles will be possible, and nighttime short-skip to 1,500 miles or more will be available.

80 meters

Occasional DX to various areas of the world should be possible between sunset and sunrise when QRN levels permit on Good (G) days (see calendar), and also short-skip during hours of darkness to 1,500 miles or more.

160 meters

Following the usual summertime slump, this band ought to begin to come alive again during the hours of darkness when QRN permits. Try the days marked (G) on the calendar for best results. DX toward the east until midnight, and to other areas afterwards until dawn. Short-skip to 1,500 miles will prevail when the band is quiet. W1XU.

LETTERS

Continued from page 83

enforce. But it would be a big step in reducing RFI to consumer goods and QRM due to habitual widespread use of more than the necessary power to sustain communications (even by well-known ARRL OO stations ... clean up your own act, guys!) Maybe a few surprise FCC inspections are in order after passing rules stating possession of such high power amplifiers is prima facie evidence of power limit violation.

3. In view of the declining Novice ranks, consider dropping the 40m Novice CW allocation and expanding the phone band downward for Generals. I am sure some other frequencies would be a fair exchange for the Novices—how about giving them 25 kHz of AM/SSB at 7.275-7.3 in exchange? It is open throughout the sunspot cycle, unlike 10m. The AM privileges might encourage them to restore or build simple equipment and progress in the hobby. Some real phone privileges might whet their appetite for a General upgrade. Otherwise, consider dropping the Novice class altogether or merging it with Tech, once the code requirement is eliminated. (In reality, there are too many classes of license. Novice and Tech should be merged, as an entry level class. Leave General the way it is. Merge Advanced and Extra. Think up some names that are less goofy sounding, like class A, B, and C. The no-code Advanced guys won't clutter up the bottom 25 kHz code segment and bother us old buzzards anyway. Make the lower 25 kHz an exclusive CW-only segment to keep those pesky bit bangers out, if you are worried about it, but are you really sure that guy with the new call that blew your ears off with the 45 wpm CW wasn't using a key that said IBM on the front? Let's get real!

4. If the rumored expansion or trade of 6.9-7.0 MHz for the largely wasted upper end of 40 comes through, let's consider something sane this time for a change as far as subband operating modes. Consider something fresh, like making the low end from 6.9 for phone, a 7.0-7.025 a CW window, a digital modes segment, an "internationally aligned" segment phone portion for upper classes, possibly putting the general CW or digital segment on the top end, where they can compete successfully with the foreign broadcast. (Think of the strong commercial incentive to move to a quieter frequency when listeners complain about multiple 1 kHz beat notes from a bunch of kW CW stations. But with a good filter, they aren't going to bother hams at all. "Please" didn't work; let's try something new.)

5. Here is something really radical: Eliminate all subbands on 40 meters altogether. That way, the more popular modes will spread out as needed, without the constant expensive "tweaking" of regulations. It seems to work OK on 160m. During the 160 CW contest the "CW band" magically grew all the way past 1925 kHz. Two days later, it shrunk back to the old 20 kHz bottom. The sun still came up. In fact, many foreign countries don't have any subbands at all. The downside is that we might have to make up some meaningful license test questions instead of mindlessly memorizing the junk on a chart everyone keeps at their operating positions. Hmmm ... the other bands? Nahhh! Too easy!

These suggestions, while offered in a humorous way, are meant as serious alternatives to the perpetuating of a problem which has been around as long as I have been in the hobby. Let's fix it this time, either through the ARRL and FASC, or take it on internationally if necessary, in spite of the resistance to change from here in the US. We could lose our frequencies due to lack of use, or due to selling of new ham gear (at truck stops) to bootleggers. I am bothered by the fact that I have not received any sort of opinion poll regarding the Morse issue, nor do I know anyone who has. I had to call ARRL HQ in order to find out who to write to, though the article I mentioned at the beginning of the letter seemed to invite comments. I hope this is not the sign of "business as usual" from the "Morse Forever" bunch. This could be our last opportunity to set a number of critical matters right.

Troublemaker. You're trying to use reason to argue what is a religious matter. Waste of time... Wayne

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The entire contents ©1996 by 73 Magazine. No part of this publication may be reproduced without written permission of the publisher, which is not all that difficult to get. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromat Way Ltd. of Hancock NH.

Contract: Upon reading this agreement, you have entered into a legally enforceable business arrangement whereby you WILL write a report on your latest ham gear and submit that manuscript for publication in *73*.

Bioelectrifier Update

The May article by WA8YKN has generated a good deal of controversy. FAR Circuits is making a circuit board for the unit and has been doing a brisk business. One chap in Hollywood with a number of friends with AIDS bought a bunch of boards and put them together for his friends.

In another couple of months I hope we'll have laboratory-confirmed AIDS cures to report. One fellow, who was in bad shape with AIDS, used the unit for several weeks, then called Mike (who makes the units commercially) to say he had astounded his doctor by rebuilding his T-cell count. Another chap had a mother who was all bent over with Lyme disease. Two weeks later she was in excellent health and walking straight. But these, and a bunch more, are just anecdotes. I want to see carefully done lab reports of before and after. If this is the placebo effect, it sure seems to be powerful.

Mike reported one other effect. The unit apparently raises the temperature of the blood, which may also help to discourage viruses, as well as the 50 µA hotfoot.

Mike sent me a copy of his Bob Beck-approved circuit, which is a little different from the Miller circuit in the May issue. Let me know if you're interested in my publishing it.

Diplomacy

Details are seeping out of the meeting between the League and the representatives of the group asking that the ham 144 and 450 bands be re-allocated for low Earth orbit (LEO) satellite communications. The League team went into the meeting angry as hell over the audacity of a commercial group even suggesting such a thing. Either they take the two ham bands off their list right now or the League would sic the hams on them and Congress.

Our beloved postal service is already making billions delivering tons of such complaints to Congress from citizens whipped into a letter-writing frenzy by the professional lobby groups, so what's a few thousand more? Big deal! The LEO group was unimpressed.

So El League-o ran an editorial in *QST* asking the members to flood the LEO group, the FCC and Congress with mail. This was repeated in hundreds of obedient club newsletters, with apparently no one involved giving any thought to the ramifications. Well, people often do really stupid things when they get mad, and the Leagsters were not just mad, they were outraged.

The predictable happened. The LEO group was not only not intimidated by the mail, they got mad and their interest in a diplomatic solution to the problem blew away as the war escalated.

The League initiated a war. An unnecessary war. Worse, they did it without any real ammunition. The League seems to have forgotten that amateur radio, for all the "service" rhetoric in the FCC rules, is a hobby, pure and simple. Oh sure, within my memory amateur radio contributed to the advance of communications technology, and helped save our country's collective ass in WWII by supplying some 40,000 hams for the military. But on a "what have you done for us lately" basis, we are running on empty.

Of course if you count providing communications for walkathons as public service, then we get a few Brownie points. Let me ask a question. How many of you even know a ham who has provided a valuable emergency service in the last five years? I doubt that 1% of us has provided a truly valuable public service in years.

The courts, by the way, have rejected our claim of being a service and have ruled that amateur radio is a hobby. Well, our courts aren't always wrong.

From the FCC's viewpoint we're a whole lot of trouble and expense, with few redeeming qualities. And please remember that like most of us, gratitude is one of the FCC Commissioner's least-felt emotions. So the marvelous things we were doing before the League's even less-thought-out "Incentive Licensing" debacle of 30 years ago gutted the hobby (and the industry), are no longer even talking points, much less ammunition for a war with commercial interests.

If the League officers and directors would get over their unfounded feelings of self-importance and recognize that the reality is that they are the publishers of a ham magazine devoted to a hobby which is of interest primarily to elderly white men, they might be in a better position to deal with what is obviously going to be a flood of seekers after our bands.

Sure, there are things the League could do which could rebuild the value of amateur radio as a true service, and I've discussed these in my editorials. But I haven't seen even a hint that the League (aka *QST*) is open to making any changes which would help our (and their) future.

Old QSLs

While looking through some boxes in the barn I came across a carton of old QSLs. Ah, memories. I'll never forget the morning in 1947 when I heard a faint signal in the 20m DX band calling CQ. I heard "W...portable...." i couldn't make out the call or where he was portable so I called "W question, portable question" a couple of times and stood by. His signal gradually got better and I found I was in contact with W7IMW/C7 in Tientsin, China. Wow! Bill was modulating a 10th-watt signal generator and using a longwire. AM, of course. His penny postcard arrived via an FPO in China. My signal with a kW was only S-5, so you can imagine how weak his was. Talk about QRP!

The PK1AW card isn't very remarkable except that I made the contact as a result of a CQ call for Asia. I'd just finished a round table where we had stations on five continents. I needed that sixth for a 20-minute WAC, so I called CQ Asia and back came PK1AW. A small coup, but memorable.

I also ran across some cards left over from my operating on Fiji, Tahiti, and the Samoan Islands. No, I won't forget one minute of those DX operations.

If I'd Only Known Then What I Know Now!

You *would* have known then—if you'd read my editorials. So I don't want to hear you whining when you have a heart attack, a stroke, or I visit you when you're tied to a rocking chair in a nursing home (like they did to my mother). But no,

LETTERS

From the Ham Shack

Mike Woolard KE4MTM/DA4WM. I must say that I look forward to getting your magazine in the mail every month, second only to my paycheck. After reading your "Welcome Newcomers" column in January, I'm sure that the majority of the Techs shown in your graph felt put down! Please stop calling us CBers. We have as much ambition, interest, and learning ability as the next guy. I am now in my 40s, and a respectable GS-12 with the government as an Equipment Specialist. While I respect the skill and talent required in both golf and code, and see the enjoyment offered in both, for me and others they're about as interesting as watching mud dry! Don't take me wrong. I'm not knocking either one, they're just not appealing to everyone. Back in 1976 I got sick of CB but interested in electronics. I bought a used ham rig, book, code tape, and went for it. In a short time I was ready to ace the written test, but I had trouble with the code. Eventually I sold everything. In 1990 I heard that the code requirement had been dropped for the Tech license and there was a world of things I could get into—like packet, satellites, etc. In 1991 I took my no-code Tech exam in Savannah. My son (then 15) followed suit, prompting my wife to get her license as well. Meanwhile, I practiced the code, passed my written General exam, practiced the code, learned my Advanced material, and practiced the code! I know every square inch of the 10 wpm wall. Perhaps my trouble is ... I never intend to use code. I don't know; it's just a means to an end for me, and a silly one. Now I'm in Vilseck, Germany, and work right across from the MARS station, where I thought I would find a few hams. These young men do everything: packet, satellites, HF, digi-pictures, and have some real nice equipment. Yet, I haven't met one person there so far who knows code or what the ARRL is! I want to learn theory, application, fundamentals, and the like, not the code! I am never going to walk around with a key in my pocket, or report an accident with a key. With so much to learn, I prefer to use my time learning theory, thank you. I still enjoy turning on my Yaesu on 20m to listen, and would enjoy getting on if I could.

Two points, Mike. One, as I explained in my editorial, the license statistics tell us loud and clear that no-code Techs are not upgrading. There has been an enormous growth in the Tech ranks, and no change in the General growth. Second, if you have reached a code plateau that's proof positive that you have not been paying any attention to my editorials. With my code learning system there is no wall, no plateau. You and tens of thousands of Techs are being frustrated by trying to learn code the ARRL way (and most other code courses too), where you start slow and gradually speed up. That is a terrible way to try and learn the code. In a few hours, almost anyone can copy code at 20 wpm. Forcing you to learn the code is the ham radio form of hazing, like being paddled to join a college fraternity. And, for many, it's almost as painful ... Wayne.

Peter Bergman NØBLX. Thanks for the tip about cayenne pepper. I don't know what else it does for me, but it sure helps with my sinus problems.

I'm getting tired of the whining about the code. Like you've said many times, it isn't that tough to learn if you really want to. Unlike theory, code classes can coach you, but you have to learn it yourself. My biggest thing right now is coaching my six-year-old daughter for the Novice ticket. She nearly made the written on her first try! As a result, two of my junior ops and my XYL are working on it.

Have you read Temple's *Sirius Mystery*? It's the most scholarly book I've seen in the anomalous knowledge field.

Yes, I have the Temple book. I've also seen a couple of excellent TV reports on this incredible report on extraterrestrial contact. I may add this to my list of books you're crazy if you don't read. This is part of my fairly fruitless effort to get people to become better educated ... Wayne.

Roy Pollitt KD4HC. Wayne, your editorial in the August issue was dead-on and highly appropriate for amateur radio circa 1996. The Atlanta Hamfest, from what you described, sounds like just another proof of the impending demise of our hobby. The signs are all around: (1) No real participation or interest by anyone under the age of 30. (2) No activity on the non-phone portion of the low bands (160m through 40 m), 75% of the 24-hour day. (3) Club activity in most areas is either dull or non-existent. (4) Cliques and good-ol'-boy networks on VHF-FM. (5) The cancellation of the Novice Roundup due to a lack of interest. (6) The transformation of ham radio into CB.

I have not attended a hamfest since 1992 because I've heard nothing but complaints about hamfests from other hams since 1985, and the complaints keep getting stronger and more detailed. Why should I drive miles and spend money on a motel room, only to find a hamfest similar to the one you described in Atlanta? Ham radio community, wake up—the end is near, unless we do something to turn the situation around.

Some suggestions: Make sure your local and school libraries are well stocked with ham magazines and books (a good club project). Find an active local club and join it. If there isn't any, start one. Get on the air and do something more than rag-chew. Start sending QSLs for your new contacts. And join the ARRL. Sure, the League has done some stupid things, but how can you influence them if you are on the outside looking in? Join and make your viewpoints heard.

Those are some good ideas for attracting newcomers, but that isn't going to make hamfests more fun. Hamfest committees are running on empty when it comes to ideas, despite my many suggestions in past editorials. Hamfests have hardly changed since my first hamfest in 1938. One more thing: In the almost 60 years I've been an ARRL member I can't recall a time when the members were paid any attention. Most of the ARRL directors I've known have held the members in contempt as sheep. You have a lot more clout as a prospective member they have to woo. Once they have your money, you've lost your clout (voice). Please remember that the ARRL is primarily a multimillion-dollar publishing business ... Wayne.

Mike Grimes K5MLG. It is rare that an author can write about complex concepts using simple, understandable terms and be interesting without talking down to the reader. Such is the case with Peter Stark and his series of articles, "Communications Simplified."

I would like you to know how much I am enjoying the series and his approach. I have covered the literature for many years, and even though I am not a beginner, this series has been one of the best and well-written I have ever encountered. The illustrations and analogies support the ideas extremely well; and, although I know the subject, it held my attention, was not boring, and expanded my understanding. He must be an excellent teacher at the community college!

Thanks for an interesting set of articles. I hope there will be more.

Robert White DDS I read the "Bioelectrofier" article, which one of my referral patients brought to me, with great interest. He was referred by Paul Keys DDS, who is undoubtedly the world's foremost infectious disease expert in the dental field. Unfortunately, tooth decay and gum diseases have been treated, and continue to be treated, primarily as non-infectious diseases. In other words, dentistry targets fixing the damage, not finding the causes, which are specific microbes, fungi, protozoans ... maybe even viruses. I'd like to get a Bioelectrofier so I can begin to further my research with electrical current therapy.

QRX . . .

Toby Metz KB7UIM named 1996 "Young Ham of the Year"

(Saugus CA) Toby Metz, a 16-year-old amateur radio operator from Meridian, Idaho and Agoura Hills, California, has been named the 1996 "Young Ham of the Year," according to Award Administrator Bill Pasternak WA6ITF. The award is jointly sponsored by Pasternak's Saugus, California-based *Amateur Radio Newsline*, Yaesu USA Corporation of Cerritos, California, and *CQ* Magazine of Hicksville, New York.

Metz, whose ham radio callsign is KB7UIM, recently moved to California from Idaho. He was selected based on his work with introducing amateur radio to the deaf in the community of Boise, Idaho. Toby explained that his involvement with the deaf came as the result of a scouting project that quickly became a public service.

"I knew I needed an Eagle project, so I began brainstorming with my friend Rich Dees (AA7WG) on how I could bring the handicapped into this picture while also using ham radio. We began talking about the possible ways that the deaf might use ham radio and realized that it would be natural for them to use packet radio."

Toby decided to start a ham radio training class for the deaf. He enlisted the help of a woman from his church who worked with deaf people in Boise. Through Toby's perseverance and her assistance, a small but enthusiastic training class came into being. Metz says that it was a class that quickly grew.

"We started off with three people but the class became larger when family members decided to come as well...(one student) even learned code using a device that converts sound to vibration that you can feel with your fingers."

Toby Metz's Eagle Scout project drew praise from the handicapped community in Boise. It also brought Toby to national prominence when he was asked to write up the project for last November's *73* magazine.

In addition to his work with the deaf, Toby assisted in the creation of a Ham Radio Explorer Scout Post in Meridian Idaho and spent over a year hosting an on-air discussion group known as the "Discovery Net." Toby presided over this gathering until a few nights before he departed Idaho late this spring. At its peak, Toby's "Discovery Net" had almost three dozen ham radio operators taking part.

New to southern California, and now a student at Agoura Hills High School, Toby says that two of his priorities are joining another ham radio club similar to the one he enjoyed in Boise and to become an Explorer Scout.

"Now I am interested in the adventure aspect [of scouting]. I want to do high-adventure camping, 50-mile hikes, rafting, and those kinds of things."

Toby Metz was nominated by Rich Dees (AA7WG) of Meridian, Idaho. Dees, who helped bring Toby into the exciting world of Amateur Radio, describes his young protégé as a born leader.

"Toby Metz KB7UIM epitomizes what young folks need to be like today. He is a hardworking young man and one of his goals is to make a difference. He took on a project aimed at making a difference [in these peoples' lives] and he did," says Dees.

Dees adds that Toby continues to want to make a difference in the world: "... and I think that young people need that as a role model."

Metz will receive his award on August 17th at the Huntsville (AL) Hamfest Grand Banquet. The presentation of the award as a regular feature of this prestigious amateur radio convention has been made possible through the generosity and kindness of the Huntsville Hamfest Planning Committee and its chairman, Scotty Neustadter N4PYD.

Making the presentation will be *Newsline* producer Bill Pasternak WA6ITF and Judging Committee chairman Larry Zettwoch KR4IF, along with representatives of Yaesu USA Corporation and *CQ Magazine*. These two companies are the corporate underwriters of the "Young Ham of the Year" award. They will be joined by three former award winners: Kevin Boudreaux N5XMH (1993), Allison Zettwoch KD4CKP (1994), and Adam Weyhaupt N9MEZ (1995).

As "Young Ham of the Year," Metz will receive (courtesy of Yaesu USA) an expense-paid trip to the 1996 Huntsville Hamfest along with a gift of Yaesu ham radio equipment. *CQ Magazine* will treat Toby to a week at Spacecamp-Huntsville, and will present him with a variety of *CQ* products. *Newsline* will provide Adam with a commemorative plaque at the award ceremony.

Both corporate underwriters of the "*Newsline* Young Ham of the Year Award" are world leaders in their respective areas of amateur radio product support. Yaesu U.S.A. Corporation is a trailblazer in the design, manufacture and distribution of high quality amateur and commercial two-way radio equipment. *CQ Magazine* is published by CQ Communications, Inc.

On learning of the selection of Toby Metz as this year's winner, Kevin Karamanos WD6DIH, Yaesu's Amateur Radio National Sales Manager, released a statement congratulating him.

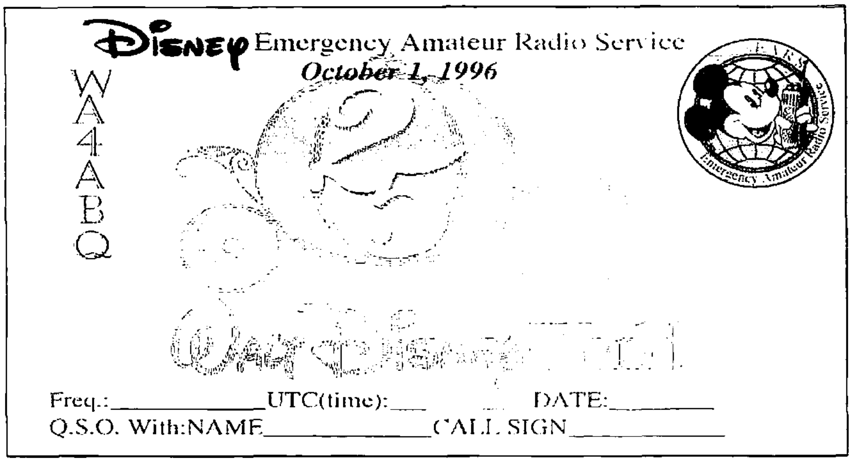
Karamanos said: "Yaesu is pleased to see so many fine young people nominated for this award and who have become so deeply involved with Amateur Radio. This is the primary reason that we support this award program. To us, Toby Metz is an excellent example of today's American youth and we join with all of the nation's radio amateurs, young and old, in commending him on his great public service and other achievements at such a young age."

CQ Publisher Richard Ross K2MGA agreed with nominator Rich Dees that Toby sets a good example for American youth: "Any time you worry about the youth of this country, and the kids with problems who are so often in the news," Ross commented, "you can look at kids like Toby and take heart. The kids in trouble are not typical. And while Toby is not typical, either, you realize that there are many more young people out there who are like Toby than those who are like the kids in trouble. They are tomorrow's mainstream and tomorrow's leaders."

The Amateur Radio Newsline is the premiere on-the-air news and information service to the worldwide ham radio community. The *Newsline* "Young Ham of the Year" award program, (formerly the *Westlink Report* "Young Ham of the Year") now entering its second decade, is presented annually to a licensed radio amateur who is 18 years of age or younger and who has provided outstanding service to the nation, his community or the betterment of the state of the art in communications through the amateur radio hobby/service.

Past recipients of the "Young Ham" award include Shawn Alan Wakefield WK5P, of Bartlesville, Oklahoma (1986); David Rosenman KA9PMK, of Muncie, Indiana (1987); Jonathan Binstock NK3D, of Potomac, Maryland (1988); Erin McGinnis KAØWTE, of Topeka, Kansas (1989); Mary Atestra KB2IGG, of Staten Island, New York (1990); Richard S. "Sammy" Garrett AAOCR, of St. Louis, Missouri (1991); and Angela "Angie" Fischer KBØHXY, also of St. Louis (1992); Kevin Boudreaux N5XMH, of New Orleans, Louisiana (1993); Allison Daneen Zettwoch KD4CKP, of Louisville, Kentucky (1994); and Adam Weyhaupt N9MEZ of Alton, Illinois(1995).

TNX to Bill Pasternak WA6ITF.



Isn't that just the DEARest thing?

D.E.A.R.S., Disney Emergency Amateur Radio Service, marks its 25th anniversary of public service this year. Does everybody have to transmit using the Mickey voice?

Ultimate Power!

Station power from a dead UPS.

Paul Blum KF9GQ
1138 Cardinal Lane
Green Bay WI 54313

One of the main reasons I became a ham is that I love to build elec tronic gadgets. This hobby gives me plenty of excuses to build things to better equip my station. Sometimes the gadgets I build actually work, and occasionally I build something that turns out better than "store-bought."

Recently I was offered a broken UPS (Uninterruptible Power Supply) for the right price (free). I gladly took it, thinking of salvaging some parts and that maybe the gel cells were OK (a free battery for my QRP rig!).

The unit sat around collecting dust for a while, until one day as I was cleaning up the shop I noticed it and decided to pop the cover off. There is quite a collection of parts to scavenge inside one of these, and I especially noticed a stout power transformer, and numerous power transistors mounted on heat sinks. There were also four 6-volt gel cells in good shape (yes!).

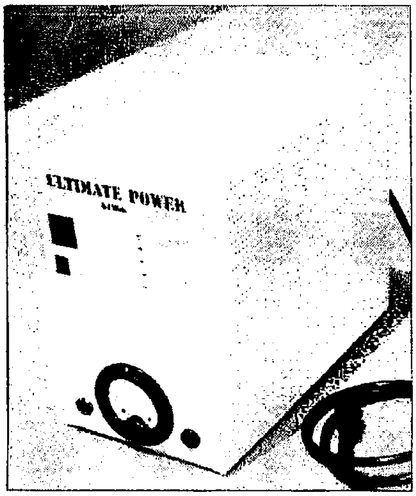


Photo A. The completed "Ultimate Power."

"The crowbar can save any equipment hooked up from destruction–especially your expensive radios!"

Inside the UPS

For those unfamiliar with UPS units, they are used to power critical electronics devices with 120-volt AC. If the commercial power fails, the UPS will provide power from batteries almost instantaneously. Usually they are used to provide short-term power for computers, providing power during an outage long enough for the computer to do a "clean" shutdown. This prevents "crashes" and data loss. Uninterruptible Power Supplies come in many sizes and shapes, depending upon current duty and battery size. Electronically, a UPS consists of a battery bank, a DC-to-AC inverter, and the sensing/switching circuitry. Some also "condition" the AC power, removing noise and RF, and also provide surge protection.

I looked up the numbers on the power transistors and found out they were N-channel power MOSFETs, with very good current handling specs. These transistors can be very useful, as they are high gain, low "on" resistance (less than 0.5 ohms), and you can parallel them directly without bulky current-balancing resistors. It turned out I had 16 of all the same type, already mounted on heat sinks.

I was intrigued by the large power transformer. In theory, the UPS takes low-voltage, high-current DC, switches it on and off to drive the transformer primary, and the secondary produces 120-volt AC. I wondered what voltage I would get if I reversed the transformer and powered it with 120-volt AC, so I tried it and got 14 volts AC (rms)! From the size of the secondary winding conductors I could see it would handle a lot of current.

A good estimate of the power handling capability of a power transformer can be found in the power supply chapter of the *ARRL Handbook*. Measure the central core of the transformer with a ruler and refer to the chart, which will give you a watt rating for the transformer.

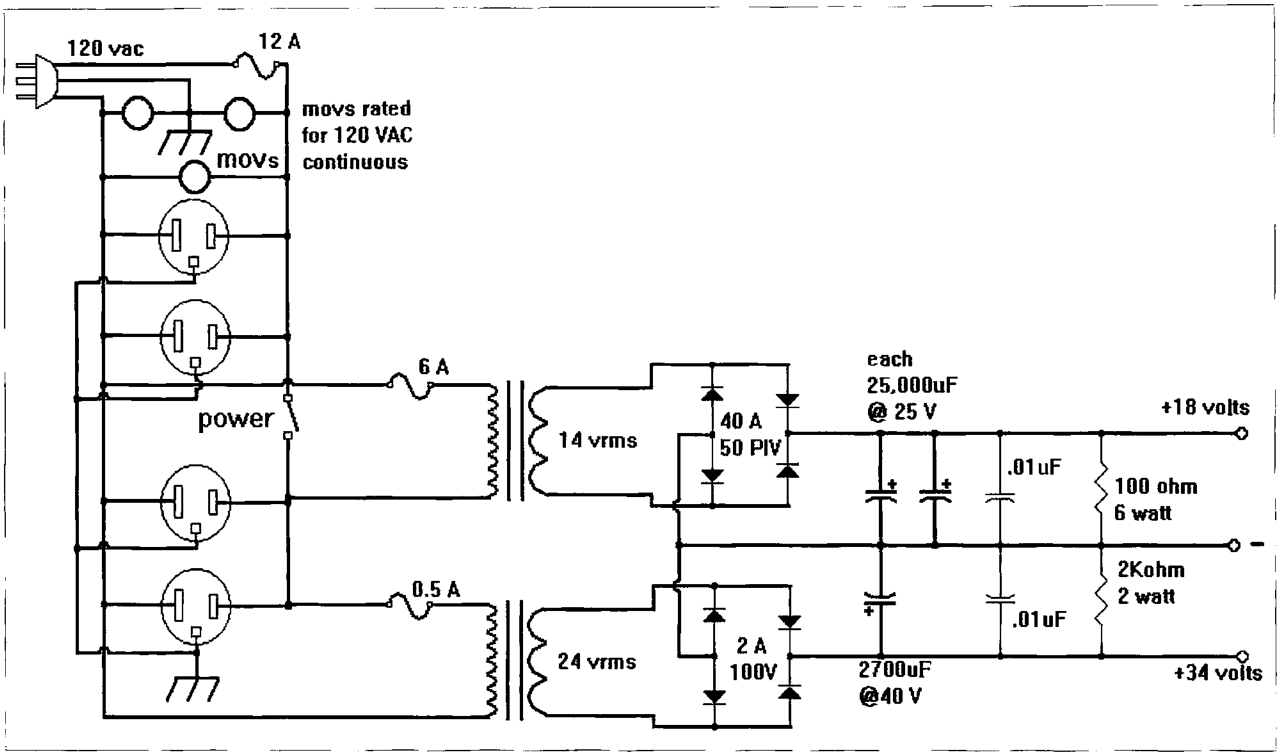

Fig. 1. "Ultimate Power" AC distribution/rectifier schematic.

Building the power supply

A UPS unit provides many of the components necessary to build a station power supply, all in one box. First, there is the box itself. If you've drooled over any parts catalogs lately, you know that a nice cabinet is expensive. Next is the power transformer, another expensive, hard-to-find item. Inside, there's a good supply of power transistors, already mounted and heatsinked. Lots of other miscellaneous parts can be used as well. I found diodes, filter capacitors, MOVs for lightning protection, and other goodies. Best of all, mounted on the rear of the cabinet are a string of AC outlets, so I set about building a "central power source" for my ham station, providing switched and unswitched AC, and 13.8 volts DC at 25 amperes.

I started with the 120 VAC side of the circuit, wiring some outlets "on" all the time and some switched. I added three MOVs across the AC input for surge protection. I fused the AC input and the two transformers separately for safety. After stripping the chassis of its dead "brain" board, I began the low-voltage circuitry. I fed the 14 VAC to a set of four 40 ampere stud mount diodes, mounted to the chassis sheet metal to dissipate heat. The diodes form a bridge rectifier, giving me 18.5 volts across the filter capacitors. I used some computer surplus filter caps; approximately 2000 µF per ampere is a good rule of thumb.

In designing the regulator, I came upon a dilemma. The MOSFET transistors would work excellently as pass devices to reduce the voltage to 13.8, but required +3 to +5 volts gate-source for turn-on. This meant that I couldn't use the same supply for the regulator drive. The other alternative is to use P-channel devices, but I had none. Luckily enough, there was another small transformer in the UPS used for charging the batteries and powering the "brain" board. It just happened to be a 24-volt transformer, so the small transformer powers the 723 regulator and the gates of the MOSFETs.

Referring to the regulator schematic, I used the ever-popular LM723 voltage regulator IC in a standard configuration. For best accuracy and minimum temperature drift, use precision 1% or 2% tolerance resistors for the sample voltage divider (the 680-ohm resistors). The high side of the divider should connect directly at the output connector, after any ammeter used, for best regulation. Use a good quality trimmer pot (250-ohm) and adjust for 13.8 volts. Make sure the pass transistors (the power MOSFETs) are adequately heat-sinked, as they may need to dissipate significant power, depending on the transformer you have. I bolted a chunk of fin stock to the UPS heat sink (heat-sink grease is a good idea) as extra insurance. Use heavy-gauge wire for high-current circuitry (#10 or #8 for 25 amperes), to and from the pass transistors and the negative return wiring.

The extras

One item that separates good power supplies from the cheapos is a crowbar circuit. I have been the unfortunate repairman of a repeater powered by a supply without one more than once, and it's definitely worth the few dollars as insurance. The crowbar circuit senses when the voltage goes too high (when you short out a pass transistor) and becomes a short circuit, blowing the fuse. The other cheap insurance policy, of course, is to have the proper size fuse! The

crowbar can save any equipment hooked up from destruction—especially your expensive radios! Hook up the crowbar circuit across the +13.8-volt output of your supply.

Other accents you may add to this project are an ammeter and some method of indicating output voltage. You may prefer analog meters, or some sort of digital meter or bar graph (the 3914 bar graph IC comes to mind). That's the fun of building things yourself—being creative and original.

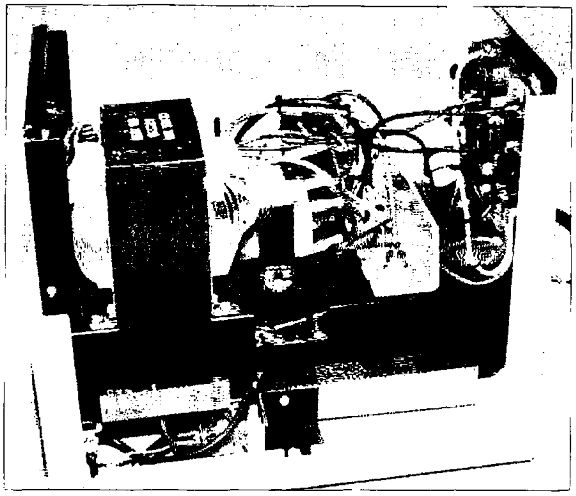

Photo B. Inside the "Ultimate Power."

How does it work?

Well, by now you want to hear how it performs. I stress-tested the supply by powering my 100 watt 2 meter FM amplifier with it. From 0 to 23 amperes, I measured less than .05 volts change in output, and less than 10 mV of ripple. The heat sink became only slightly warm after three minutes keydown.

The AC outlets allow me to power other station goodies from the same box.

All in all, I am very pleased with the performance. Credit goes to my eight-year-old son, Jeffrey, for giving me the idea to name it "Ultimate Power."

So, keep your eyes open for surplus UPS units—hamfests, auctions, or your friendly neighborhood computer geek—don't pass up a real home-brewer's bargain!

NEVER SAY DIE

Continued from page 4

the stuff I sure wish I'd known years ago and am telling you about now is going in one eyeball and out the other, while you are foolishly depending on your doctor for your health as much as I was depending on mine. Well, the sad fact is that your doctor and mine don't know much about health. Doctors don't take any courses on health or its maintenance in medical school. Few are taught even one day about illness prevention or nutrition. The result is that doctors don't know a darned thing about health. They're taught how to make repairs when things finally break down and what sledge-hammer drugs to prescribe.

For instance, though it was considered totally crazy by the medical profession just a few years ago, now there's a grudging agreement that, yes, there's a (mumble) psychological component to every illness. But you aren't going to find any doctors anywhere who are making an effort to find these emotional triggers and treat them as well as the resulting physical symptoms. If it hurts, hey, take an aspirin, and never mind that the hurt is nature's warning signal that the body is in trouble. It's like the fuse in your rig. So, if the fuse blows, put in a bigger one, right?

Are you going to come bounding up to my table at the Dayton CompuVention in 2010, or will you be doddering with a walker to reminisce with me about how ham radio used to be before we lost our last two bands a couple years back?

Colorado QRP Club's Field Day Operation

Field Day the hard way.

Marshall Emm AAØXI
2460 S. Moline Way
Aurora CO 80014

Who says the bands are dead? We are at or near the absolute bottom of the barrel in terms of solar activity and, hence, HF propagation. The bands are dead, so this should be an extended period of thinking, and building, and saving dollars to buy kilowatts, right? Wrong! Once again the Colorado QRP Club* has proven that you can do with skill, persistence, and antennas what others do with power, even when the bands are "dead."

Field Day is a trial at the best of times, and the constraints on site preparation and the logistics of manning a club operation are a challenge, but operating QRP really separates the sheep from the goats. CQC (Colorado QRP Club) has a core local membership of experienced and talented operators, who saw QRP operation in Field Day as, well, nothing out of the ordinary at all.

The results speak for themselves—close to 1200 QSOs for 10,000 points, all of them at 5 watts or less, and high ranking in the 2A Battery division, if not outright dominance. The formal results are not yet in as this is written, but the QRP grapevine functions very well. Once again, the CQC proved that if you can do it at all, the odds are pretty good you can do it QRP.

Of course, anyone with a ham license knows that power is probably the least productive of the factors that go into a QSO. We all had to learn the power equations that prove the difference between 5 watts and 100 watts is roughly two S-points at the receiving end—go to a kilowatt and you pick up another one and half S-points! To put it another way, the difference between a watt and a kilowatt is 30 dB, or five S-points.

QRP operators are also aware that losses are more critical at low power levels, so there is a lot of concentration on antenna efficiency. It follows that a large part of CQC's Field Day effort centered around the antenna farm, and what an antenna farm it proved to be!

Photo A. The 60-foot tower, ready for launching. FD Chairman KF7MD, right background, looks a bit anxious. Photos by ABØCD.

Remember, we started "planting" our farm on Friday afternoon. Despite the traditional Field Day thunderstorm, we got our crop in and here's what we were ready to harvest when the starting gun went off:

BAND	ANTENNA
ALL	G5RV @ 40'
160m	Sloper at 55' on the 60' tower
80m	2 element delta loop array, apex @ 65'
40m	3 element delta loop array, apex @ 55'
40m	Sloping dipole @ 60' on the high end
20m	3 element delta loop array apex @ 45'
20/15/10m	Tribander @ 45' w/ rotator
15m	Monobander @ 35' w/Armstrong rotator
6m	5 element @ 65' w/rotator
2m	11 element @ 65' w/rotator
6m/2m/70 cm	Beams for packet and Novice stations

Three (count 'em!) towers, and for most of us a much better selection of antennas than we enjoy at home!

We set up two HF stations with specific band and antenna assignments, as well as a separate VHF/UHF/packet station, and, of course, our Novices set up their own station (including the G5RV at 40 feet). We used computers for logging, and decided that we would forgo the all-emergency-power bonus for the sake of data security—it was our first real attempt to use computers and we didn't want to take any chances with power fluctuations or blackouts. We could have rented a generator, but the noise would have spoiled the peace and quiet of a superb site on a ridge about 50 miles southeast of Denver. A hundred feet of extension cord to a nearby house allowed us to power the computers and lights.

Operators were assigned in teams comprising an operator and a logger for each station, and the teams were rostered to cover the entire Field Day period, and we also had "site hosts," gofers, and even a chef. In fact, breakfast on Sunday morning was one of the highlights of the event.

Field Day is always a test of adaptability, and we had our share of problems to fix. Being forty miles from the nearest parts store or home QTH forces one to

be prepared, and to be flexible. There's always something you have to cobble together, and you tend to hear a lot of guys going around muttering, "It's not a contest. It's NOT a contest."

Operationally, everything went pretty much according to plan apart from an emergency rig replacement on Sunday morning. And I was a bit late for a 3 AM operating shift because a small-town policeman took exception to my velocity (but fortunately my ham license plates or my Field Day mission convinced him to write a warning rather than a ticket).

The delta loop arrays on 80, 40, and 20 were the real powerhouse antennas for HF, and we noticed an average 1-2 S-point improvement toward the east using the 3 element deltas. If you want to refer back to what I said about QRP power levels earlier, you'll see that switching antennas was as effective as going from 5 watts to 100! No activity was noted on 160m and very little on 10m CW, but for the most part we were as busy as the QRO stations.

Conditions? Well, "conditions" turned out to be pretty good, but I remain convinced that they depend as much on good antennas and operating skills as on solar phenomena. And it's surprising how often you can call CQ on a "dead band" and get an answer.

QRP operation does indeed engender skill, and knowing how to break a dogpile or the ability to copy a "1/1/9" signal can make a big difference. Probably the only significant operational difference is that it's often difficult to "hold" a frequency with a QRP signal, so we spent more time in search-and-pounce mode than calling CQ TEST. If we could hear them, we could work them. As usual, 20m phone was an alligator pit (all mouth and no ears).

It was definitely a successful Field Day, a real team effort and a credit to all who participated. But if there is one person who should be singled out, it's CQC's Field Day Chairman, Paul (KF7MD), who was responsible for planning and coordination, and kept it from falling apart. As we took down the towers on Sunday afternoon I saw him staring off into the distance and asked him what he was looking at. He replied, "I think we could run a V-beam down there next year!"

440 Yagi Link Antennas

Improve your repeater system by building new antennas for about $2 each!

Marty Gammel KAØNAN
1703 Hewitt Ave. West
St. Paul MN 55104-1128

Recently I was asked to make two pairs of link antennas for one of our local repeaters. The transmitter and receive sites were about three miles apart. The new receive sites were about eight and 10 miles from the transmitter, and only 3 watts of power was to be used between the links. (The old antennas had only three elements each, with a bad match.) Even white noise was present—not good for a repeater in the process of adding more receive sites, as well as a 6 meter input and output. So I had the task of coming up with better antennas to help improve the repeater system.

The new 434 MHz link antennas I came up with were each four elements. In accordance with good engineering standards, I chose to use different sized spacing between each of the elements for maximum forward gain on this point-to-point installation for repeater link use. I used simple gamma matches and old aluminum TV antenna booms. The new antennas worked perfectly, with a 1.1 to 1.2 SWR. They are full quieting; no more white noise on the system.

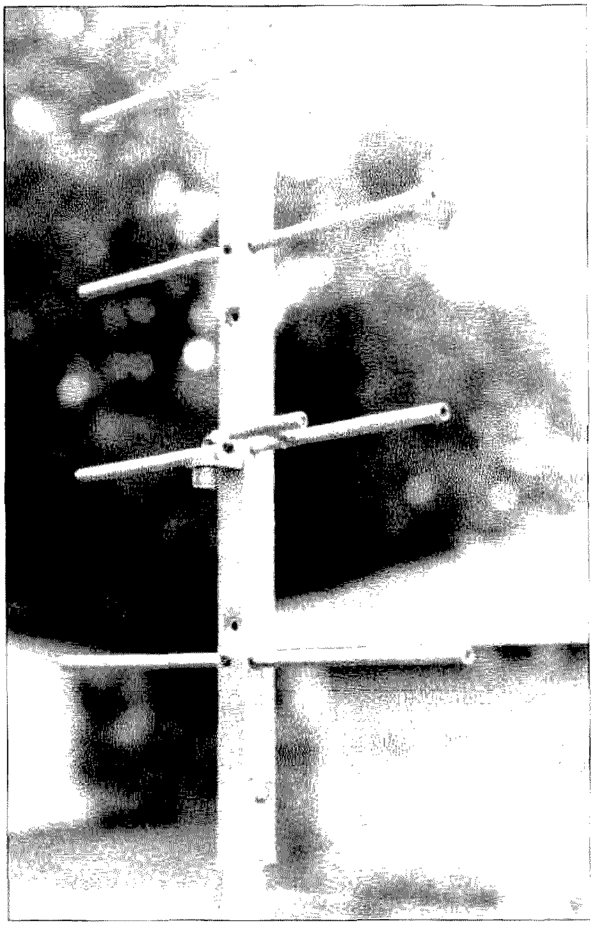

Photo A. One of KAØNAN's completed 440 yagi link antennas.

"My cost for each antenna was only a little over $2."

People are always giving me old TV antennas, so the only thing I had to go to the hardware store for was the stainless steel self-tapping screws. My junk box supplied the SO-239 fitting for the feed point, some RG-8 coax, some thin sheet aluminum for making gamma straps, and the SO-239 mounting bracket.

My cost for each antenna was a little over $2.

Building the antenna

I started by gathering together all the materials and tools needed to complete the project. First, I stripped the unwanted parts from the TV antenna boom. Usually, I drill out the rivets that attach the elements to the boom. Please remember to save all straight pieces of tubing for use in future VHF antenna projects (about the only things I throw away are the plastic element mounting pieces). If you don't have an old TV antenna to strip parts from, and you are having trouble finding 3/8" diameter aluminum tubing in your area, try your local scrap metal dealer or metals dealer. They usually sell this tubing by the pound.

Applying the formula

To determine the correct lengths for cutting your tubing for the target frequency, use the formula: 468 divided by the frequency times 12. This will

give you an answer in inches. This will give the length for the driven element; for the reflector, add 5%; and for each director, take off 2% to 3% from the driven element length.

Cutting the parts

With a hacksaw, cut a 18" to 20" piece of boom material for each antenna you are going to build. You can use a hacksaw to cut the pieces of tubing, but a tubing cutter, like plumbers use, will give a much smoother cut.

Cleaning everything

If the boom material is very corroded, you may want to use a Scotch-Brite™ pad or fine steel wool to clean it; clean the tubing for the elements while you are at it. The few minutes you spend cleaning the parts will give you a more professional-looking antenna.

Drilling the holes

Measure in 1/4" from the edge of the 1" square aluminum boom, and scribe a line for drilling the holes to mount the elements. I use a small bit first, drilling a 1/8" pilot hole for the 3/8" drill bit. Place the element holes so you have the right amount of space between each element (see **Fig. 1**).

Mounting the elements

Make a mark 1/2" each way from the center of each element, then push each element through so that you can see your marks. At this point, drill a 3/32" hole through the boom and element to secure each element permanently to the boom, using the 1" #6 screws.

Making the gamma match

I had some short pieces of 3/8" aluminum tubing in my junk box, and RG-8 coax is the perfect diameter coax to fit inside 3/8" tubing to make the gamma. Cut a strip of thin sheet aluminum or brass for the gamma strap; a piece 3/8" by 3-1/2" will make a suitable strap (if you don't have any in your junk box, you can get some at a hobby shop or craft store). Bend one end of the gamma strap around the gamma tube, using pliers to get a snug fit. You will want 1/2" of space between the gamma tube and the driven element to get the antenna to

"You can use a hacksaw, but a tubing cutter will give a much smoother cut."

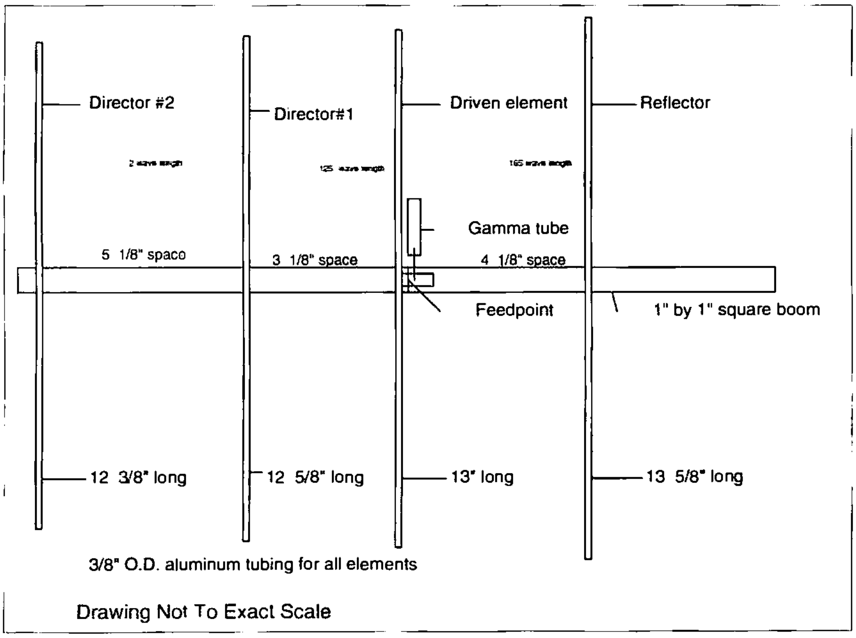

Fig. 1. Construction details.

load properly. Use the pliers again to bend the strap around the driven element to get a good snug fit. Drill a small hole through each end of the gamma strap as close to the tubing as possible, and install a small nut and bolt with a lock washer in each hole (see Photo A). Strip about 1/2" of the dielectric off one end of the RG-8 after the outer covering and the shield have been removed. Bend the stripped end of the RG-8 so that you can solder this end to the SO-239 fitting. Drill two small holes in the other end of the feed point mounting bracket, and attach this bracket to the boom with self-tapping sheet metal screws.

Making the feed point

While you still have the tin snips out, cut a piece about 7/8" by 2-1/2" for the feed point mounting bracket. Next, cut or drill a hole 1/2" in diameter to mount the SO-239 threaded fitting (this depends on the fitting you choose to use) near one end of the 7/8" by 2-1/2" feed point mounting bracket (look closely at **Photo A**).

Now compare your antenna to the one in the photo. Recheck all your measurements before proceeding with the tuning procedure.

Tuning the antenna

To check the SWR, I mounted the four-element yagi link antenna onto the end of a piece of tubing so that it pointed straight up, away from any nearby wires and objects. Then I slid the gamma strap along the driven element to find the best match. After that, I tried sliding the gamma tube in or out until I found the best SWR reading.

Anyone with questions about my antenna design may write to me at the address above. For a prompt reply, please enclose a #10 S.A.S.E. along with your questions.

Parts List
For <u>each</u> antenna:
Tools needed:
Hacksaw
Screwdriver
Pliers or wrenches
Drill bits
Tin snips or shears
Tape measure
Tubing cutter (optional)
Drill press (optional)
Scotch-Brite™ pad or fine steel wool

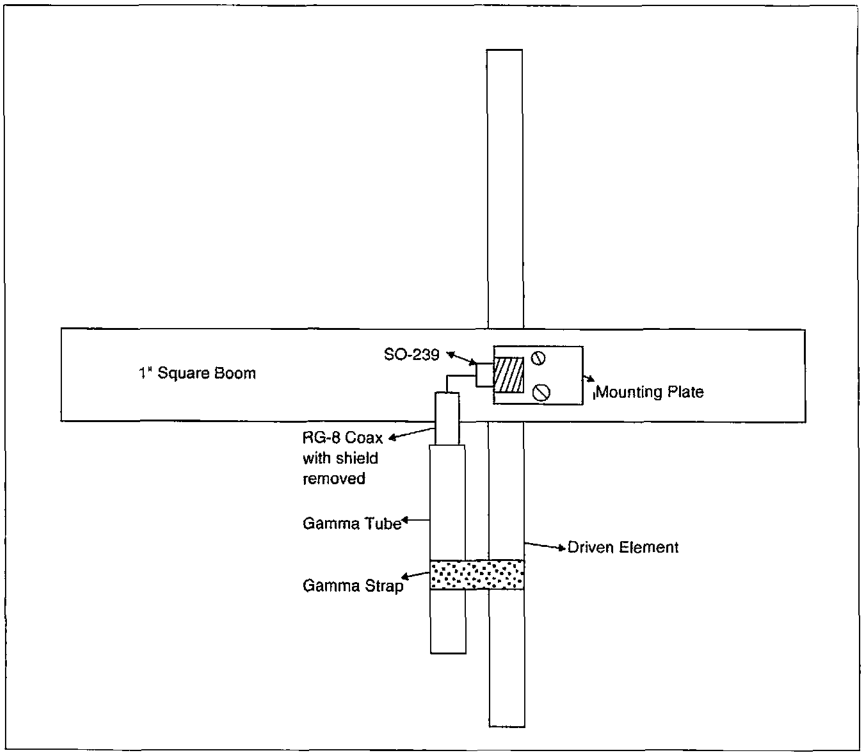

Fig. 2. Gamma detail.

A Versatile QRP Random-Wire Antenna Tuner

A quick way to tune up your QRP rig in the field.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30 - c/o Defendini
Salinas PR 00751-0030

When QRP rigs are taken on camping trips, you usually use an end-fed random-length wire tossed up into a tree for an antenna. To match the unknown impedance of the antenna, a tuner is necessary, and an SWR meter is needed to adjust the tuner.

An L-network is the circuit normally used to match the antenna to the rig. However, there are three possible L-network circuits, only one of which will produce a minimum SWR match with a particular length antenna wire and operating frequency, especially when modified by local conditions and structures in the vicinity such as wire fences, trees, and overhead wires. The height of the antenna, the conductivity of the ground, and Murphy's law can also complicate matters.

Usually, L-network tuners require input and output connections among three specific points in the L-network to be swapped around until the proper circuit configuration is discovered. This is not only tedious and time-consuming, it is also no longer necessary.

The tuner described here is designed so that once input and output connections are made, a twist of a knob allows the operator to select among the three possible circuit configurations, allowing rapid tune-up using whichever internal circuit provides the best match and lowest SWR, which equates to the lowest reflected power.

This tuner also includes a simple circuit which allows you to monitor reflected power. It does not require calibration because it is the minimum reflected power which indicates the best match possible between your transmitter and the particular antenna in use. Further, the reflected power meter sensitivity is made variable with a panel control so this tuner can be used equally well by QRP and QRP_p operators. The reflected power meter doesn't measure SWR: it only shows the point of best antenna matching.

For those of you who say, "But I want to *know* my SWR!" I offer the following facts:

1. The rationale for using any antenna tuner is to obtain the *best match possible* between the rig and the available antenna.
2. Minimum reflected power indicates the *lowest SWR possible* with the rig and antenna.
3. *Knowing* the exact standing-wave ratio at the lowest reflected power will not reduce the reflected power even a microwatt.

The point is that you don't have to know the actual SWR figure in order to get the optimum match between your transmitter and a given antenna.

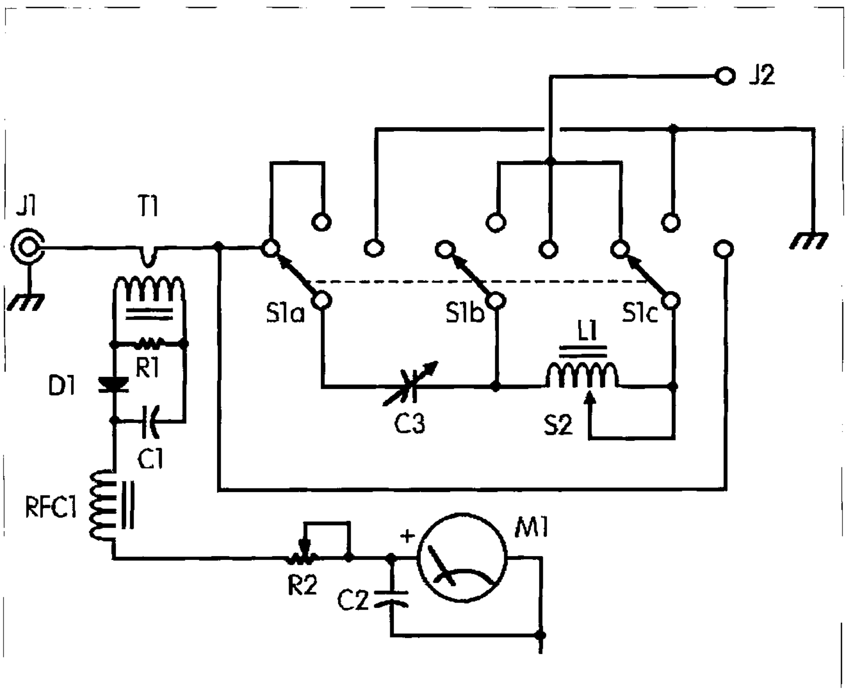

Fig. 1. Schematic diagram of the Random-Wire Tuner.

The circuit

Refer to **Figs. 1** and **2** for the following discussion. The heart of the circuit is the L-network, consisting of C3 and L1. Switch S1, a three-pole, three-position rotary switch, allows you to change the configuration of C3-L1 among each of the three basic circuits illustrated in **Fig. 2**. The numbers assigned to each circuit are the same as the positions of S1.

L1 is a tapped toroid with taps every two turns to allow the greatest flexibility in tuning. The taps are selected by S2, a one-pole, 12-position rotary switch. C3 is an air dielectric variable capacitor. Both capacity and inductance are controlled by knobs on the front panel.

RF applied at J1 flows through the primary of T1 to the L-network selected by S1, then to the antenna at J2.

The voltage developed in the secondary of T1 is rectified, filtered, and applied through sensitivity control R2 to meter M1. R2 allows you to keep the meter needle on scale while adjusting C3 and L1 to obtain the best match, indicated by the minimum dip of the needle on M1.

Construction

Although this tuner will function equally well if built on a breadboard, it's best to construct it in an enclosure so it will not be damaged when jammed into a backpack. I recommend using an aluminum box, or one made of blank printed circuit board material.

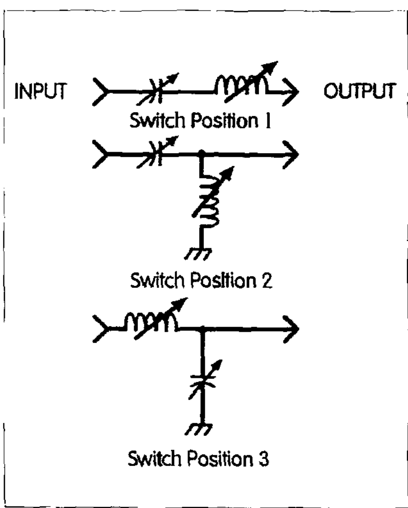

Fig. 2. L-network circuits.

C3 *must* have both rotor and stator insulated from ground! If possible, use an insulated shaft coupler and a short piece of 1/4" rod through the panel; the control knob can be affixed to this rod later.

You can make an insulated shaft coupler from a short length of 1/2"-diameter Plexiglas™ or Lucite™ rod, available from hobby and model shops (see **Fig. 3**). Drill a 1/4"-diameter hole lengthwise through the center (use a slow speed so the drill bit does not melt the plastic!). Then drill and tap setscrew holes through one side of the rod to accept 6-32 screws to secure the shaft of C3 and the short rod extending through the panel. Taking apart a defunct potentiometer will supply both a short piece of 1/4" shaft and a panel bearing.

To prepare T1, wind six spaced turns of AWG-22 wire on an FT37-43 ferrite toroid core. Space the turns evenly to cover about 70% of the core. Leave an inch or so of wire at each end for later connection. Coat the winding with liquid polystyrene, such as General Cement Q-Dope®. Allow it to dry for several hours, then add a second coat and allow that to dry.

L1 must be wound with 24 turns of AWG-24 wire on an FT50-43 ferrite toroid core, tapping it every two turns. Taps can be formed most easily while winding, by forming a loop about an inch long and twisting the wires together. See **Fig. 4**. These twisted loops will be cut, stripped, tinned, and soldered directly to the terminals of S2 later.

After winding L1, check to see that you have a twisted loop tap every two turns. There should be exactly 11 taps, with two turns of the main winding at each end. Then coat the winding with liquid polystyrene as detailed for T1, making certain not more than 1/4 inch of the twisted taps are covered where they leave the surface of the core.

Using a small piece of perf board, mount and connect the following components: T1 (mount upright with the bare core portion on the perf board and secure with a bit of epoxy or hot glue), R1, C1, D1, and RFC1. Connect a short piece of insulated wire to the junction between R1, C1, and the ground end of T1, and leave the other end free. Connect another short piece of insulated wire to the bottom end of RFC1 and leave the other end free. These two wires will be connected later. Set this assembly aside.

Prepare the panel and cabinet as desired, with the proper holes for C3, S1, S2, R2, and M1. Lead lengths are not important but should be made as short and direct as possible when wiring later.

Since the capacitor you will use for C3 is unknown, you will have to make certain it is mounted so it will be *insulated* from ground, as well as lined up so its shaft is directly in line with the panel hole for its control.

Connect jumpers between the proper terminals of S1 as shown in **Fig. 1**. Solder insulated wires a few inches long to each of the wiper contacts of S1a, S1b, and S1c. Leave the other ends free. Now mount S1 on the panel.

Mount the following components: J1, J2, R2, and M1. Solder a length of wire between J2 and the point indicated in **Fig. 1** on S1. Double-check to make sure that you have connected this wire to the proper point on either S1b or S1c, which are jumpered together.

Secure the insulated coupler to the shaft of C3. Mount C3 on its insulated mount and make certain its shaft is lined up exactly with the matching hole in the panel. If you install the panel bearing in this panel hole and insert the short length of shaft through the bearing, it must insert easily into the insulated shaft coupling before tightening the mounting of C3. With an ohmmeter make sure that both the rotor and the stator of C3 are not grounded. Tighten the setscrew on the short shaft extending through the panel, making sure it is not pushed so far into the insulated shaft coupling that it shorts the rotor of C3. Place a knob on this shaft and rotate C3 through its range. It should rotate smoothly without binding. Correct any misalignment until it rotates freely.

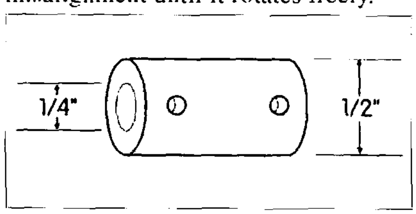

Fig. 3. Home-brew insulated shaft coupler.

When L1 is dry, clip the loops of each tap at its outer end. Strip the enamel off both wires of each tap, twist them together, and tin them with solder. Leave them long; they will be trimmed later.

Bend each tap so it is perpendicular to the flat surface of the toroid. Refer to **Fig. 5**, which shows the proper connection of L1 to S2, with the switch terminals assigned numbers. Carefully slip the taps, and the end of L1 connected to terminal 1, into the switch terminals. Use care so each tap enters its assigned switch terminal.

Snug L1 to within about 1/4" of the rear of S2, which will support L1. Solder taps 2 through 12 only. Clip off the long ends of the tap wires extending through the switch terminals.

Connect a short length of wire between the wiper terminal of S2 and terminal 1. Solder the wiper terminal only. Mount the S2-L1 assembly on the panel.

Route the free end of the wire connected to the wiper terminal of S1c and connect it to S2, terminal 1, then solder. Clip off any excess wire. Locate the loose end of L1 near tap 12 and route it to the wiper terminal of S1b, then solder it. Connect the free end of the wire connected to the S1b wiper terminal to *either* the rotor or stator terminal of C3, then solder. Clip out excess wire.

Connect the free end of the wire from wiper terminal 1 of S1a to the remaining unused terminal of C3, then solder. There is a jumper already installed between terminal 3 (clockwise, looking from shaft end) of S1a to terminal 2 of S1c. Connect a wire from either terminal to ground and solder both connections.

Mount the perf board assembly previously wired so a wire from the center connection of J1 can pass directly through the center hole of T1; this will form the primary winding. Solder a wire to the center conductor of J2, route this wire through the center of T1, then solder it to S1a, terminal 1 or 2, which are already jumpered together.

Connect the wire leading from RFC1 to terminal 3 (clockwise looking from the shaft end) of R2, and solder. Strip about half an inch of insulation from a short length of wire and feed this bare end through the remaining two terminals of R2, and solder both terminals. Connect the other end of this wire to the positive terminal of M1. Connect C2 between both terminals of M1. Connect a short length of wire to the negative terminal of M1 and solder both terminals of M1. Connect the free end of the wire from the negative terminal of M1 to ground.

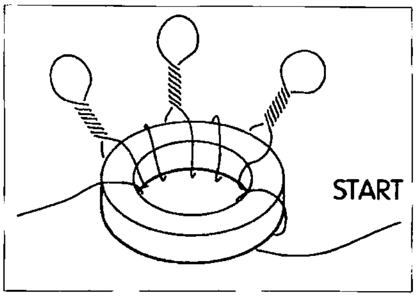

Fig. 4. Winding L1 with taps (partial).

Check all solder connections and compare your wiring to the schematic in **Fig. 1**. Repair any errors and double-check to make certain that both terminals of C3 are insulated from ground *only* with S1 in position 1, furthest counterclockwise. One terminal of C3 connects to ground through L1 at S1 position 2, and directly at S1 position 3.

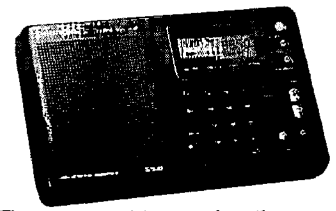
Operation

Connect the output of your QRP transmitter to J1 and an end-fed wire antenna to J2. Rotate R2 fully counterclockwise (maximum resistance). Set C3 at mid-range and S2 at position 6.

Key the transmitter and adjust R2 for an indication of reflected power on M1. Switch S1 back and forth, watching M1 for any dip, however slight. Leave S1 where the dip occurred, and adjust C3 and S2 for the deepest dip, adjusting R2 clockwise a bit as the meter needle falls.

Although this is probably the best match, leave R2 where it is after noting the position of the needle on M1, and try adjusting C3 and S2 with S1 at each of the remaining positions. If either position of S1 provides a *deeper* dip—less reflected power—than that first obtained, this is the correct S1 position for the best obtainable match.

It should be possible, adjusting the tuner as just described, to get the reflected power indicated by M1 at or



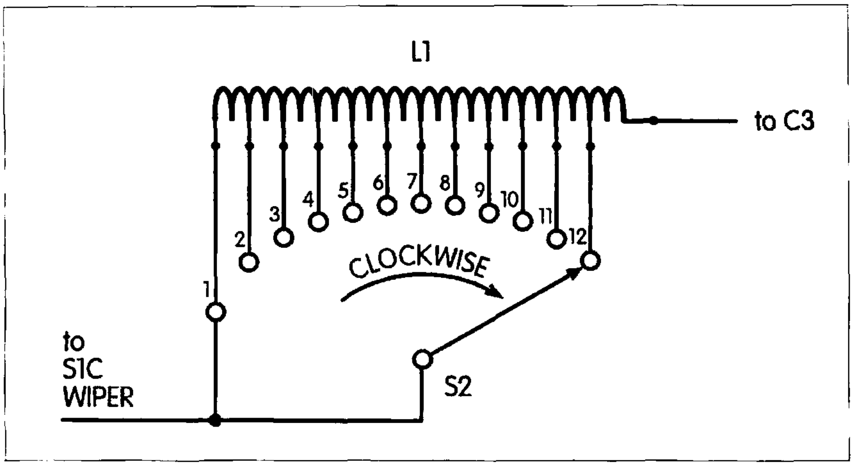


Fig. 5. S2-L1 connections, expanded rear view.

very near zero, even with R2 fully clockwise (minimum—zero—resistance). You may or may not achieve an exact 1:1 SWR—no reflected power—but properly adjusted, this tuner can achieve less than 1.5:1 SWR with just about any combination of transmitter, antenna and frequency over the HF bands, and usually *much* less than that.

It may be impossible, because of the simplicity of the reflected power circuit and the RF inside the tuner, to achieve a zero reflected power indication on M1, especially with R2 set for maximum sensitivity—no multiplier resistance in series with M1. Normally, there would be a fixed resistor in series with R2, or R2 would be a set-and-forget trimpot establishing the maximum reflected power at full scale of M1 in a calibrated circuit. However, I purposely made this circuit to have the maximum sensitivity possible, controlled by the operator, so the reflected power circuit would produce meaningful results when operating in the milliwatt range.

Regardless of the above, when you have achieved tuning which provides the deepest dip on M1, this is the *best match* you can achieve with the antenna and frequency in use. When you have achieved the deepest dip you can, adjust R2 to place the meter needle on any convenient scale marking. Then as you operate, especially if you change frequency by very much, check the position of the needle. If it has risen higher, a slight tweaking of C3 will usually return it to its previous setting.

A few hints

Some operators stick a long nail into the earth to ground their outdoor stations. Others use a wire counterpoise in addition to an earth ground, or instead of one. Properly chosen, a counterpoise will work very well, as long as *it is not a multiple of a half wavelength at the operating frequency.* A half wavelength or multiple thereof of wire, open at the far end, places a very high impedance at your station ground point, the exact opposite of the low impedance necessary. A counterpoise a quarter wavelength or an odd multiple thereof in length and open at the far end is also an impedance transformer, but in this case it inverts the high impedance at its open end to a very low impedance at the station ground post, exactly what is desired. However, when changing bands, make sure your quarter-wave counterpoise is not a half wave long on the new band!

If you use a monoband rig, carry a quarter-wavelength counterpoise for that band, regardless of the length of your random wire antenna.

If yours is a multiband rig, prepare a quarter-wavelength counterpoise for *each* band. Connect them together at one end and attach to your station's ground post. This way you will always have the correct length counterpoise as you hop from band to band.

Rather than using separate wires to make the multiple counterpoise, consider using a length of indoor telephone wiring cable which contains four, six or eight separate wires. Cut it to the length needed for the lowest frequency band. Choose the number of wires needed—one for each band—and connect them together to a spade lug or similar which will connect to your station ground. With a pocket knife or X-Acto® knife, make a slit a quarter wavelength from the ground post end in the outer insulation, clip one wire, and remove the unwanted portion of this wire from the other end of the cable. Do this for each band for which you need a counterpoise. Now you have a neat insulated cable which contains all the counterpoises your multiband rig will need in the wild. This cable will be equally useful at the home station, especially if you live above the ground floor or your ground connection is fairly long. 73

Parts List

C1, C2	0.01 µF disc ceramic
C3	Variable capacitor, 300 pF to 400 pF maximum
D1	Germanium diode (1N34, 1N60, 1N90, 1N270, etc.)
J1	RF connector, builder's choice
J2	Insulated binding post
L1	24 turns AWG-26 on FT50-43 core, tap every two turns
M1	100 or 200 µA DC meter
R1	51 Ω S% 1/2W carbon resistor
R2	25k Ω linear taper potentiometer
RFC1	1 mH miniature RF choke
Toroid	FT50-43 (L1)
T1	6 turns AWG-22 on FT37-4 core (see text)
S1	3P3T rotary switch
S2	Single pole 12-position rotary switch

Operating RS-12

It's easy!

Luis F. Orozco N5UHB/XE2MXU
Montes Claros 3413
Monterrey NL 64949
Mexico

Whenever someone mentions satellite communications, we tend to think about expensive rigs and complex antennas. Fortunately, there is one satellite out there for those who don't have a "satellite station," or who just want to get started in satellite communications. The minimum equipment required to use RS-12 is an HF radio capable of operating "split" on 10 and 15 meters, and a 10/15 meter dipole. This means that most people who use HF already have all they need to get on the air with RS-12!

How do I do it?

RS-12 was launched on February 5, 1991, and it orbits the earth at an altitude of about 1,000 kilometers. You probably won't work any "long haul" DX (maybe in a few years!), but you should have no problem making cross-country contacts (see **Fig. 1**).

Presently, RS-12 operates in Mode K. The uplink frequency is from 21.210 to 21.250, and the downlink from 29.410 to 29.450. The ideal setup to work this bird would be to have two different radios with two different antennas. However,

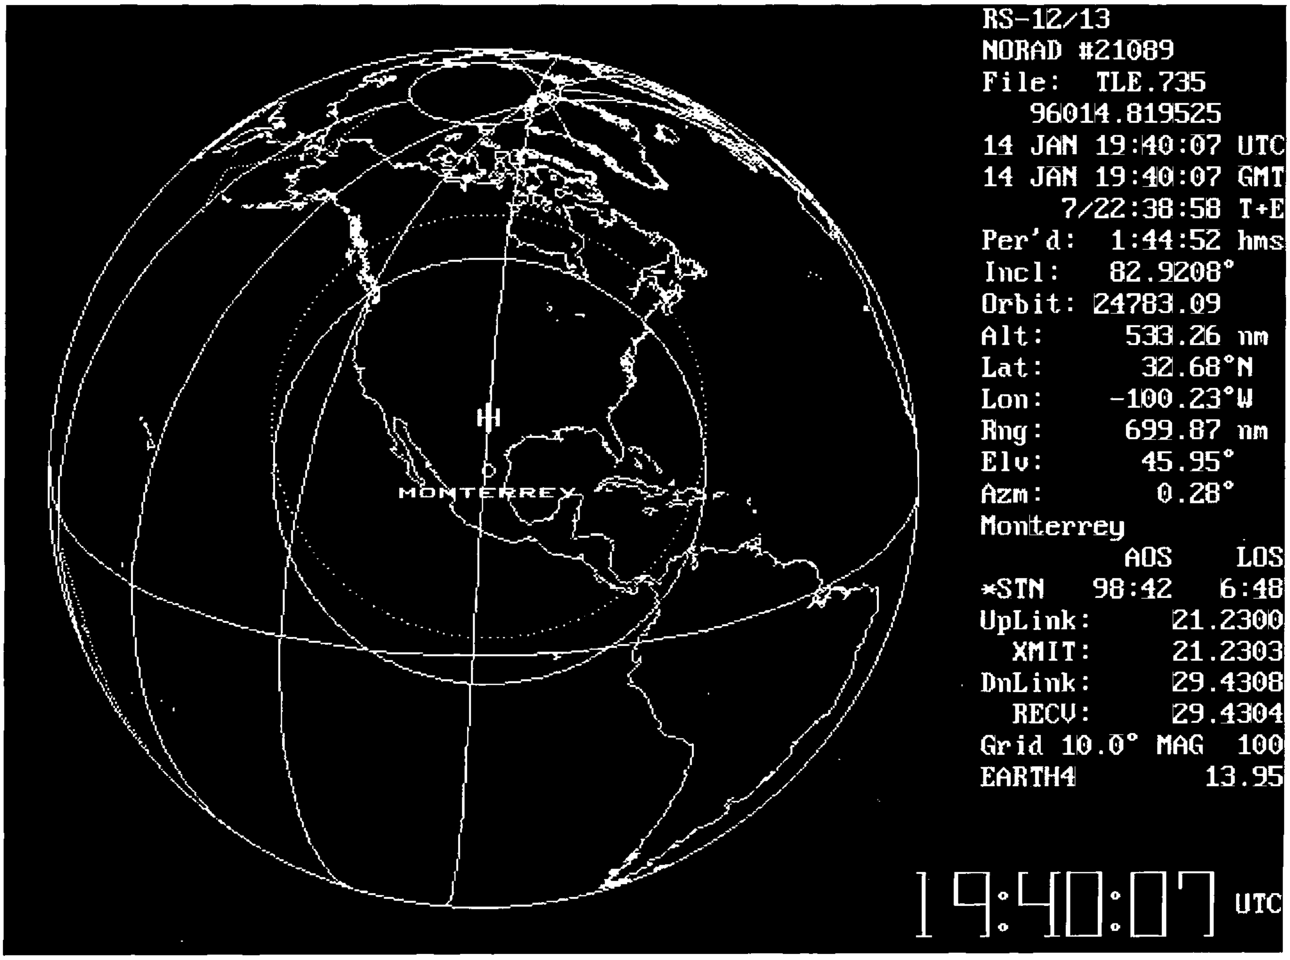

Fig. 1. Screen dump from STSPLUS's orthographic projection showing RS-12 passing over northern Mexico and the central US.

most hams have just one HF radio, which is fine as long as it has two VFOs. You still have the choice of what kind of antenna configuration to use. You could use just a 15 meter dipole since you won't be doing any transmitting on 10 meters. However, if you want to pull all the weak signals out of the noise, I would recommend making a dipole for each band and feeding them with the same coax. The antenna height is not very important here, as long as it has a somewhat clear view of the horizon (well, as clear as you can practically get without buying a new tower).

In order to know when the satellite will pass over your QTH you will need a satellite tracking program. There are quite a few of them out there, but I would recommend using STSORBIT PLUS, by David Ransom. Besides having great graphics, it is very accurate and fairly easy to use. If you have Internet access you can get the latest version at http://www.ozemail.com.au/~dcottle/. **Fig. 1** is a screen dump of STSORBIT PLUS's orthographic projection. If you don't have Internet access, find a local ham who does and ask him to get the program for you.

"Besides having great graphics, STSORBIT PLUS is very accurate and fairly easy to use."

In order to make accurate predictions with STSPLUS, or any other tracking program, you will also need Keplerian elements. These are a specially formatted set of numbers that specify the location of the satellite at a particular time. You simply plug them into the tracking program and let it do the number crunching. Files with Keplerian elements for all amateur satellites (plus many, many other satellites!) are also available at the above address. Keplerian elements are also distributed through packet bulletins, so you don't need Internet access to get them.

Getting to work

Now that you have all the gear set, you need to know how to use the satellite. This is fairly simple, and you should have no problems working anyone you hear after a little practice. First, put your radio in "split" mode and set the transmit frequency to 21.230. Your signal should be "coming out" on 29.430 (plus or minus the Doppler shift; more on this later). From there you can move up or down to whatever frequency you want (within the satellite's passband, of course). Since this satellite has a linear transponder, if you move your uplink up by 1 kHz you should also move your downlink up 1 kHz.

One final thing that you should take into account is the Doppler shift, which is caused by the satellite's motion. If you're using STSPLUS ORBIT, enable the Doppler shift prediction feature using the F8 key while the map is displayed. If your program doesn't have a Doppler shift feature, you can operate by trial and error. First choose an uplink frequency and tune your receive VFO to your corresponding downlink frequency, without taking into account the Doppler shift. Then make a call, and start tuning around your downlink. When using RS-12, the Doppler shift can be up to about 2 kHz, so tune 2 kHz up and down from the initial frequency until you hear someone answering your call. As the satellite goes by the Doppler shift will change, so you will need to continually readjust your receive frequency. You should also make sure you are not transmitting on top of someone else.

Finally, a word about power: Don't run the linear when 100 watts will do the job just fine. And don't run 100 watts when 10 watts will do it! If too many people get on the satellite and are using too much power, signals will start to fade and it will be a lot harder to work other stations.

Working satellites is a lot of fun, and RS-12 is the perfect bird for those of us just starting out. See you on the air! 73

A Multiband Trap Dipole Antenna System

This easily-constructed HF antenna system is a perfect combo for use with portable rigs.

L. VanProoyen K8KWD
8330 Myers Lake NE
Rockford MI 49341

It's been said, "there's nothing new under the sun," and so it is with this antenna system—its basic design dates back more than 40 years. What's unique about this antenna, however, is that it's a complete system, including a matching unit that I've found ideal for use with the newer compact HF rigs that do not include a built-in tuner (Kenwood's TS-50, ICOM's IC-706, etc.). And it's easy to build using components and parts which you should be able to locate at your local hardware store and/or in your junk box.

Trap dipoles

I've built several trap dipole antennas over the years, but the design that's worked best for me is that originally described by C. L. Buchanan and subsequently modified by Arthur Greenberg a number of years ago (see Bibliography). It used a single pair of traps resonating somewhere around 7.2 MHz to give "five-band" coverage, and this basic design, or some modification of it, has been carried for many years in various handbooks and antenna manuals. I've further modified this original design to use coaxial-cable traps in place of the open-wound inductor style originally used, to make the antenna a bit more rugged. **Photo A** shows the construction details of the traps I currently use.

While the original traps worked fine, but turned out to be high-maintenance items. No matter how well I tried to shield them, water invariably found its way in. Also, the originals, having a somewhat larger diameter, were good wind-catchers, which caused the antenna to come down a lot—usually resulting in something getting broken, like one of the ceramic capacitors. This type of capacitor has proved to be somewhat hard to find, and is usually expensive when you *do* find one. Since changing to coaxial cable traps, I've had a version of this antenna up for several years without having any of these problems.

"A multi-tapped coil, selector switch, variable capacitor, and a couple of coax connectors are all the components needed to build this L network."

Most trap dipole antennas represent a compromise over a full-length antenna, either in terms of bandwidth or performance, or both. This antenna by itself really worked satisfactorily on 40 meters and on a portion of the 80/75 meter band. Operation on other bands and/or full 80/75 meter coverage really requires the use of some type of matching unit. Previous rigs I've used having internal tuners worked fine, generally managing to load the antenna even on WARC bands. Since acquiring a TS-50, I needed some kind of external matching unit in order to use this antenna effectively, but I didn't want to use some big, bulky, or expensive tuner—thus the L network. **Photo B** is a picture of the L network matching unit I came up with.

L networks

L networks have been used as effective matching devices for a number of years. Their popularity fell off some during the heyday of TVI, however, because an L network's attenuation of harmonics or other spurious signals is not as good as that of a Pi or T network. From a simplicity standpoint, though, an "L" is hard to beat. Also, newer rigs typically use well-designed bandpass filters that do an excellent job preventing radiation of harmonic signals, making this shortcoming somewhat less of a concern.

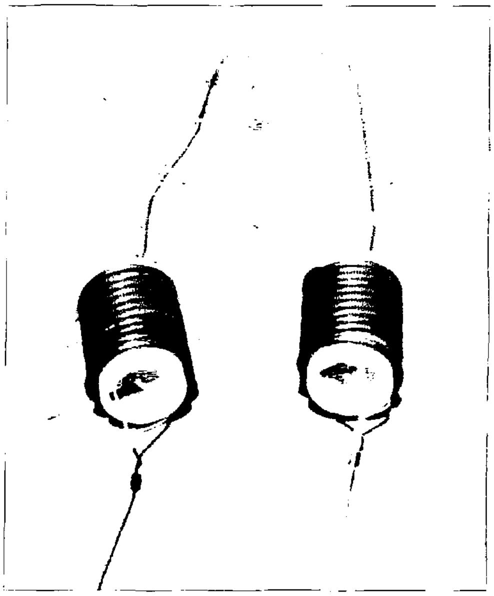

Photo A. Coaxial cable trap construction details.

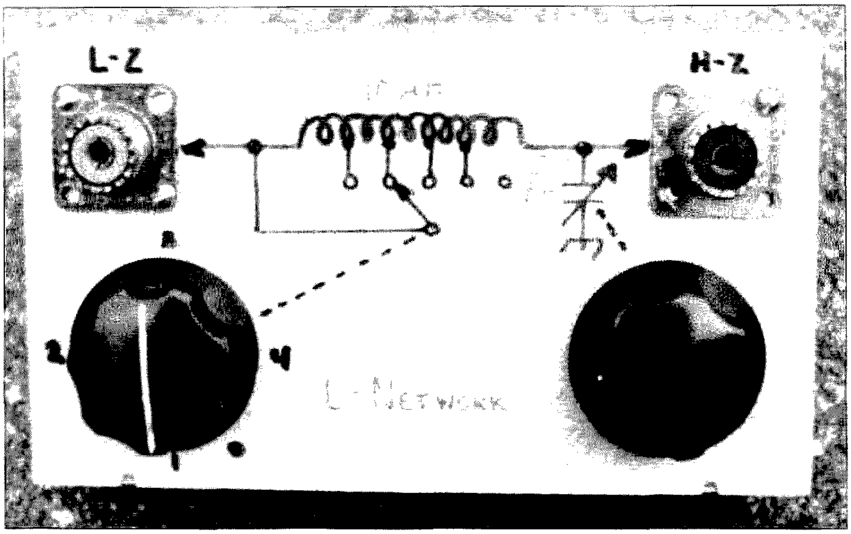

Photo B. The L network matching device.

The unit I use is small (see **Photo B**), measuring just 2" x 3" x 5", so it works quite nicely for portable operation. L networks can be arranged in a series/shunt (or shunt/series) fashion using capacitor-capacitor, inductor-inductor, or inductor-capacitor arrangements. The configuration I used has a series inductor with a shunt capacitor (see **Fig. 1**). This style permits matching low impedances to high when connected normally, and high to low when reverse-connected. L networks are bidirectional in terms of input and output, which makes them extremely useful in a variety of matching applications.

While originally intended for use with my trap dipole, I've since found this L network to be generally useful in both portable and mobile operation. It does a good job, for example, in matching my TS-50 to a variety of antennas, including random wire types and a mobile whip. If I can't find a match with it connected one way, I simply reverse it and try again. However, 75 meter mobile operation does require use of an additional base loading coil.

Building the L network

As shown in **Photo C**, a multi-tapped coil, selector switch, variable capacitor, and a couple of coax connectors are all the components needed to build this L network. It's built in a mini-box enclosure similar to one available from Radio Shack (#270-238, which is 5-1/4" x 3" x 2-1/8"), and wired as shown in **Fig. 1**.

The inductor used was made from an available section of mini-ductor stock, but a custom-wound coil can be made using a 3" piece of 3/4" PVC tubing as a form. It should be 23 turns of #16 or #18 wire, spaced to fill the 3" form to give approximately 10 µH inductance. (Some brands of PVC tubing are more suitable than others for RF applications. A quick test can be made by heating a sample section in your microwave for 15 to 30 seconds. If the sample appears to have warmed appreciably, I'd recommend trying another brand. I'd also suggest using some technique other than touching the sample to determine if it has been warmed by the microwave—the wrong stuff could be *very hot!*)

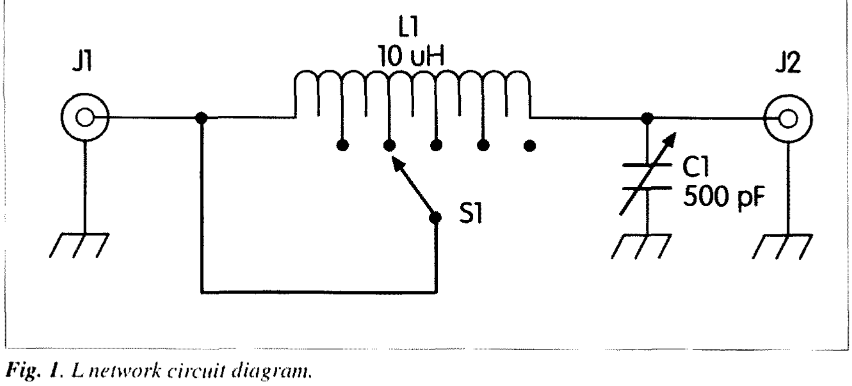

Fig. 1. L network circuit diagram.

For my matching network, a five-position ceramic switch was used to select five tap points on the coil. The tap points were distributed evenly along the coil every four to five turns to match the switch positions. A switch with more positions would be better, as finer inductance steps could be selected, but this one was available from the junk box. A suitable substitute would be the 12-position switch sold by Radio Shack™ (#275-1385). Using a switch like this would require tapping the coil about every second turn, but would give great incremental resolution.

The capacitor used is an old broadcast replacement type having a maximum capacity of around 500 pF. Capacitors like this are getting harder to find but show up frequently at hamfests. Should your junk box fail you, Antique Electronic Supply of Tempe AZ carries a capacitor similar to the one used here, as well as others, as standard catalog items.

"I've found this system ideal for use with the newer compact HF rigs that do not include a built-in tuner."

Another viable option for the required shunt capacitor would be using the 12-position switch previously mentioned to select a series of 50 pF fixed capacitors. This switch is a shorting type which would make wiring something like this fairly easy. Should you try this option, I would suggest selecting capacitors with 500-volt or higher ratings.

Constructing the antenna and traps

My original five-band antenna's traps used a pair of 5 µH inductors shunted with 100 pF capacitors. Since the overall length of a trap dipole is largely governed by the inductive component of the trap coils, I wanted to get as close to the original design parameters as possible because I didn't want to alter the antenna's size significantly (at just over

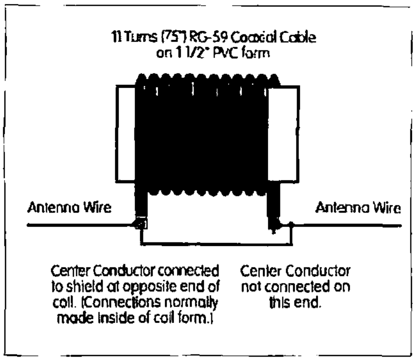

Fig. 2. A) Coax-cable trap circuit.

100 feet overall length, it fits nicely in the space I have available for it). With this objective and a desire to build traps with reasonable "Q," I chose RG-59 foam cable which has about 17 pF per foot as a good compromise for my new traps.

The traps are wound on a 1-1/2"-diameter by 4-1/2"-long PVC pipe forms which have a 2" outside diameter. I ended up using 75" of cable per trap in 11 close-wound turns to resonate near 7.15 MHz. This works out to approximately 100 pF and 5 µH, which is very close to the original design values and doesn't significantly affect my overall antenna length (or performance). **Fig. 2a** shows the trap circuit, and the construction details are shown in **Fig. 2b**.

After winding the cable on the forms, I drilled termination holes for the cable and wired the shield from one end of the coax to the center conductor of the other end, as shown in **Fig. 2a**. I then drilled two 1/8" holes, directly across from each other, at each end of the PVC form and ran some bare #12 wire through to form connecting points to tie the traps to the antenna wire. Finally, after soldering all connections, I sealed the coax cable ends with RTV sealant, coating everything completely to ensure that no water would get into the cable. **Photo A** shows details of the completed traps.

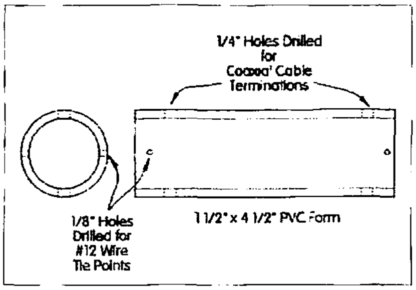

Fig. 2. B) Trap construction details.

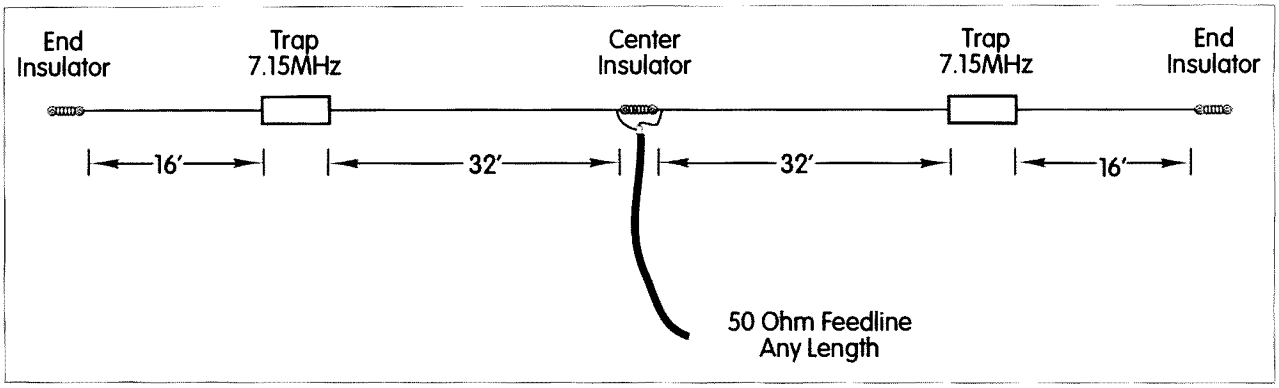

Fig. 3. Trap dipole construction details.

I originally intended to run egg insulators through the centers of my traps to provide strain relief, but I never got around to it. So far, the 1/8" holes in the PVC forms have not pulled out, and the antenna is still up, but using some type of strain relief is a good idea.

The antenna wire was attached to the traps using the dimensions shown in **Fig. 3**. I used #12 electrical wire with the insulation left on for the actual antenna wire. I typically buy Romex™ cable and strip it down to recover the individual wires. This stuff is cheap and makes good antenna wire.

I'm currently using RG-8 cable to feed the antenna, but I have used RG-58 or RG-59 (70-ohm) in the past with equally good results. In fact, the 70-ohm stuff is probably a better choice for this antenna, especially when using it with an L network matching device.

Tuning and operating

If this antenna is built using the dimensions shown and used with the L network described, no further antenna tuning should be necessary. Should you want to fine-tune it a bit, the 32' lengths (see **Fig. 3**) could be adjusted for resonance at 7.2 MHz or so, and the 16' lengths adjusted for your favorite part of the 80/75 meter band. If you have access to a grid-dip meter, you might also want to check the traps for resonance. However, I've built several sets of these traps and have found that when using 75" lengths of RG-59 cable (Radio Shack #278-1319), they always resonate where expected.

Having a built-in SWR indicator would probably facilitate adjusting the L network since my TS-50 does not include this metering function. I initially used an in-line meter with it until I became familiar with its operation. Now, I simply tune it for maximum output power as indicated by my TS-50's meter (relying on its SWR protection power cut-back circuitry). I generally use the 50-watt power level when tuning in order to offer some protection to the transceiver.

As previously mentioned, I've had this antenna and matching system for a few years now, and its performance has been excellent. I have on occasion had a full-length 80 meter dipole up, and in most instances my signal reports have been as good or better with this antenna system whenever I've made comparison tests. 73

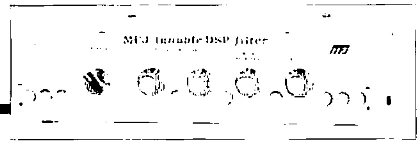
73 Review

The MFJ Tunable DSP Filter

So little noise, you might think you're the only one out there.



Jeff M. Gold AC4HF
1751 Dry Creek Road
Cookeville TN 38501

If you can't hear 'em, you can't work 'em, so your receiver has to be able to separate the noise and signals. Sometimes the unwanted noise appears in the form of adjacent signals, especially during contests. There have been considerable advances in using computer technology to help you zero in on the signal you want and get rid of other signals and noise. Many new transceivers come equipped with Digital Signal Processing (DSP).

What are the rest of us to do? You add a good DSP unit to your existing rig. MFJ's 784B is a tunable DSP filter that has many functions. It is a 16-bit machine that runs at a 12 MHz clock speed. This allows the DSP to interpret the incoming data very rapidly and decide what is information and what is noise.

This unit has so many noise fighting features that the manual is more like a textbook. The good news is that there is an easy-to-follow section in the beginning of the manual that allows you to get up and running right away. I work with computers for a living, so I hate to read manuals when I get home. I unpacked the MFJ filter and wanted to get it on the air in about ten minutes. I chose to use the quick start suggestions and had it in line in a very short time. You will find that to take advantage of many of the features, you *will* need to read the manual. It is reasonable to expect to put in 8-10 hours to really master all the functions of this filter.

The MFJ DSP unit is made to work with SSB, CW, AM, packet, AMTOR, PACTOR, RTTY, SSTV, WeFAX, FAC, weak signal VHF, EME, and satellite modes. The filter has fifteen pre-set filters for these modes. Five of these filter settings are locked in. You can customize filter settings using ten programmable filters. The custom settings allow you to save desired center frequency/bandwidth, low pass/high pass cutoffs, auto/manual notch, noise reduction or other settings. You can select a pre-set filter and then kick in some of the other noise-fighting features to meet the current band conditions.

The unit goes in between your transceiver/receiver and an external speaker or headphones. It uses 12 VDC or you can buy the MFJ-1315 ($14.95) adapter. The unit comes with MFJ's one-year "No Matter What" guarantee. They will repair or replace the unit for one year, no matter what you've done to it. The filter lists for $249.95, and it's an experimenter's dream. If you like to fiddle with knobs and buttons, this unit will keep you busy for quite some time.

"It's excellent for contesting because it allows you to get rid of overlapping signals."

General features

•5 factory pre-set filters
•10 programmable pre-set filters
•Tunable spotting tone—works even in narrowest CW filter position
•Adaptive tuning—center frequency tuning automatically becomes finer as you narrow the bandwidth; makes it easier to use very narrow filters
•Automatic notch—can vary aggressiveness
•2-1/2 watt audio output
•Ability to turn speaker off and use phones, or use both phones and speaker
•Reporting of active filtering (uses Morse code)
•Automatic filter bypass during transmit to monitor CW sidetone, voice or data
•Manual notch in CW mode
•Noise reduction, automatic notch and tunable notch can be used in memory mode
•Mark-Space frequency and baud rates for data modes
•Adjustable line level output
•Self-testing for all digital circuitry, switches and controls

Automatic notch filter

This filter is designed to find and eliminate unwanted heterodynes very rapidly. CW and RTTY signals can also be eliminated. The filter is extremely narrow, yet doesn't degrade voice signals. This filter is also useful for getting rid of unwanted tuner-uppers (a favorite pastime of a number of operators on 20 meters). In addition to the automatic notch, there are two manually tunable notch filters. These can be effective for separating out a CW station you want to talk to from other unwanted CW stations. On SSB the DSP did the best job when set at the least aggressive setting.

Adaptive noise reduction

This filter gets rid of background noise. In many instances during noisy band conditions, it can make the difference between picking a signal out of the noise or not. The noise reduction mode works with all the other filter modes and will work on random noise, white noise, static, ignition noise and power line noise. The filter gives up to 20 dB of noise reduction.

Tunable high-pass/low-pass filters

These filters work for both voice and data. The lower cutoff frequency can be tuned from 200-2200 Hz and the upper cutoff frequency from 1400-3400 Hz.

You can tune out unwanted signals very close by. This is an effective filter for SSB contesting because it allows you to get rid of overlapping signals. I found this filtering ability to be excellent. On shortwave listening it helps kill heterodynes from stations 5-10 kHz away.

Tunable bandpass filters

These filters work well with narrow band signals such as CW and RTTY. You can tune the center frequency from 300-3400 Hz and then vary the bandwidth from 30 Hz-2100 Hz, which gives you very sharp CW filtering (good for contesting), and wider sharp RTTY, etc. filtering. By narrowing the bandwidth you can eliminate signals that are 60 Hz away. The filters don't appear to have much problem with ringing; I used them quite a lot on CW.

Comments

One important factor with the DSP unit is to set the input level correctly. The procedure for doing so is quite clear in the manual. If you start to use the DSP and think it isn't working right, you most likely have the level set incorrectly. In most cases the pre-set filter settings did what I needed to operate in almost any type of band condition. In the two months I tested it, the unit did everything the other DSP units I have used did and a whole lot more.

The one area where this filter really excelled was when using it with the digital modes. "Out of the box, the pre-set digital modes sounded like a commercial tape. That unit works the digital modes like nothing I have ever used," Conard WS4S commented. Using the double bandpass (dbp) filter capability you can set separate Mark and Space frequencies and really get rid of unwanted signals.

I tested the filter on a Yaesu 757GXII, a Ten-Tec Argosy II, and a Kenwood 930S. Conard WS4S summed up the testing in these words: "You can get real lonely using this filter. You can crank up the filters to the point where you think there's no one else on the band. Then before depression sets in you take the filter out of line and realize that you are not alone."

Build the FOX Controller

A sneaky device to make foxhunting even more fun.

Bob Johansen WB2SRF (Sly Red Fox)
61 Burnside Ave.
Staten Island NY 10302

Once upon a time, the Staten Island Amateur Radio Association (SIARA) held a foxhunt in the Great Kills Park on Staten Island to test the DF units several club members had made. George (The Bear) NA2V volunteered to be the fox. He hid in the woods and periodically transmitted on his HT. We took bearings to determine his location, but we didn't locate him very quickly because we were getting many false nulls that were probably due to multipath.

I can still hear George growling that he had outfoxed us. Rich KB2OH finally located him. After the foxhunt was over we discussed how we might improve our direction-finding technique. Sy AA2RT asked if the transmitter could be operated automatically. Sure, with an automatic ID unit. I set out to build one.

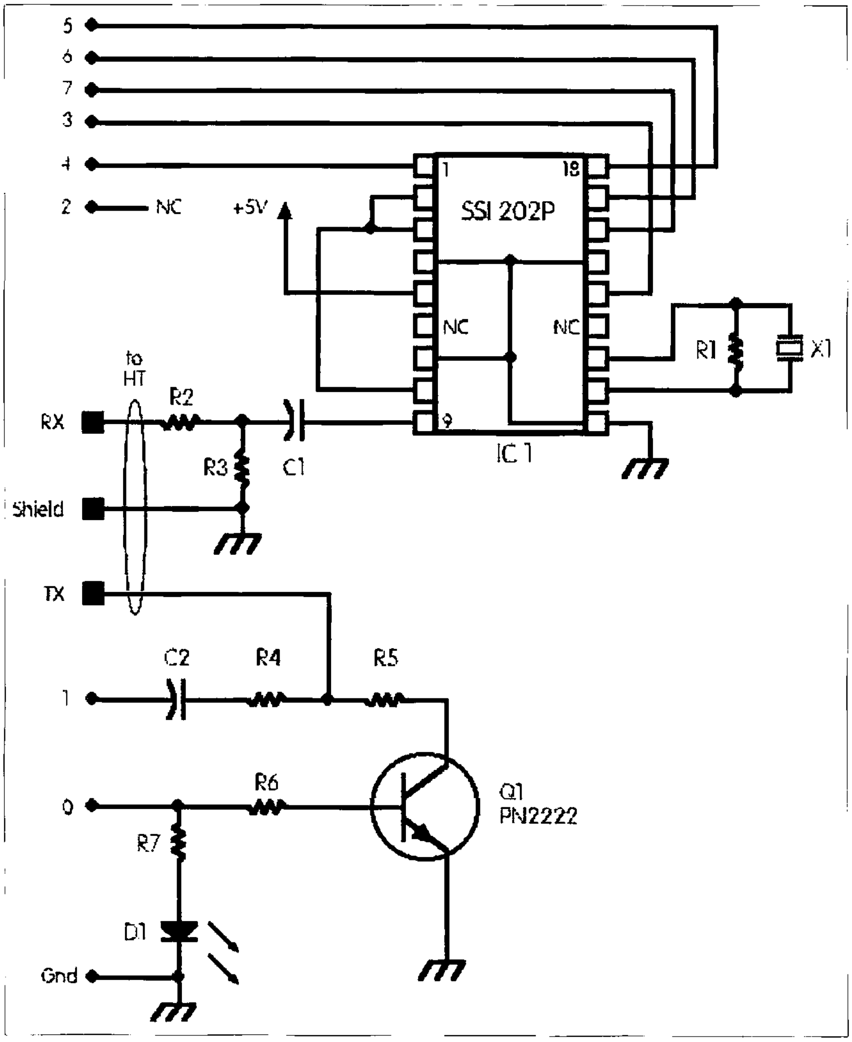

Fig. 1. Circuit for the FOX Controller. *Numbered terminals indicate connections to BASIC Stamp module.*

The BASIC Stamp

Through *73* I have learned about control circuits using devices like the 555 timer, counters, gates, and a diode matrix (a type of ROM) to serve as a controller and ID unit for experimental beacons and repeaters. Then I read about a new toy that I just had to get, Parallax Inc.'s BASIC Stamp, so I ordered one complete with the development system, from Digikey. Application Note #8, "Sending Messages in Morse Code," provided a flash of inspiration, so I adapted this program to suit my foxy needs.

The BASIC Stamp is a really neat 9V battery-powered computer/controller about the size of a large postage stamp, hence the name. It has eight I/O lines and 256 bytes of memory that can be programmed in the BASIC language using a PC development system. The BASIC Stamp board has a small prototyping area that can be used for adding custom circuitry. I used this area for a DTMF decoder and the PTT keying and audio coupling components. The FOX controller decodes DTMF commands received on a separate receiver, and keys the foxhunt transmitter accordingly. This provides for wireless remote control that can be very handy during a foxhunt. Alternately, the FOX controller can receive commands on the fox's own receiver.

Construction

You should be able to build this project for under $50 if you have any kind of a junk box. There are three different versions of the BASIC Stamp. I used the original discrete component version, which has a removable 93LC56 EEPROM and PIC16C56 BASIC interpreter IC. There are newer SMD versions that allow for a more compact assembly, but these versions do not have

a removable EEPROM (see note in Parts List).

Install and wire the DTMF decoder, PTT keying transistor and audio coupling components into the prototyping area (see **Fig 1**). I used #30 insulated wire-wrap wire as jumpers soldered between the connections. A three-pin header was used to make the connections to the HT's audio, PTT, and ground. I put the HT and controller inside a surplus ammo box equipped with a BNC antenna connector and it was all set.

Operation

Once you've built your foxy controller you'll need two HTs to transmit and receive on the same frequency. You'll probably want to offset the frequency of the fox's receiver or use the tone decoder mode of your HT so that only you can control the fox. Sneaky, huh ? The FOX controller can also listen for commands on one band (UHF) and control the fox on another (VHF).

Set your HT's volume control to the middle of its range and attach the plugs from the controller. The controller then listens for a DTMF command to start the operation. When a "*" is received the PTT line is enabled, "OK" is transmitted in Morse code, a high-pitched beep is emitted, followed by 10 seconds of carrier, then a low-pitched audio beep, then the carrier drops five seconds before resuming. This lets you know that you've contacted the FOX controller, and that it's about to key up for 4.5 minutes. If a "#" or "0" is sent at this time the operation is canceled. After 4.5 minutes it sends an ID message (WB2SRF/FOX in my unit) before releasing the carrier.

When a "#" is received, the unit will test the operation without going through the long sequence above. The PTT line is enabled, "OK" is sent, and the carrier is released.

When a "0" is received, the unit will transmit "HI HI" and then silence the transmitter (this is for when you feel someone is getting too close). Of course, when using a single HT as both the fox and the FOX controller receiver, you need to wait until the 4.5 minute timer expires before sending additional commands.

Use the lowest output power setting of the fox HT to conserve battery life and make it more difficult to find.

What next?

The BASIC Stamp/DTMF decoder combination can be used for all kinds of things. For instance, I intend to write software for selective calling and a DTMF display using a LCD panel. The EEPROM can be overwritten or removed and replaced with one loaded with different programs to suit different applications. What applications can *you* think of for this neat hardware? 73

A 30m Through 80m Loop

Great indoor antenna for QRP.

Jay Jeffery WV8R
3819 Parkdale Road
Cleveland Heights OH 44121

The reasons for designing a relatively small antenna for 80 meters are usually to get around antenna restrictions or to solve the problem of lack of space. There is another good reason, however, and that is convenience.

Consider an antenna that fits easily into a room of a house, is easy to build and repair even during the worst weather, and is simple to tune. Isn't that convenience? The difficult thing is coming up with one that's small but capable, even at QRP levels of power (5 watts or less).

The design

Having had good QRP results on 40 meters with a small, single-turn loop based on standard designs, I decided to try to scale it up to 80 meters. Using proportions, I estimated the size needed and laid it out on the dining room floor using ordinary zipcord and a 250 pF variable. I was lucky and was able to tune up on 80 meters the first try. By pruning it, I was able to use the full extent of the capacitor. I found that I could tune the 30 and 40 meter bands, as well as the 80. I also found that the loop, though technically a small loop, was not exactly tiny. It was approximately 64 inches square.

Since the antenna was to stand upright to save space, I made it 66.5 inches high and 62.5 inches wide. This favors the vertical wires, which do most of the radiating. Two advantages of having the loop upright are that it is less sensitive to being near ground level than a horizontal loop, and it has some gain along the plane of the loop. Also, interference can be reduced because of the sharp tuning characteristics of a small loop and by means of the null associated with this type of antenna.

> ***"This antenna fits easily inside a house, is easy to build and repair even during the worst weather, and is simple to tune."***

Since my house is constructed of wood, the antenna works well in almost any location; some homes or buildings have a lot of metal in their construction that could shield the antenna and cause it to work poorly. Even so, there may be a spot that will work, such as a porch or an attic space above the metal.

One drawback of an antenna in the home is the danger of an RF burn. Insulation of the exposed parts of the antenna can help prevent this, but an indoor antenna must be treated with respect when it is being used to transmit.

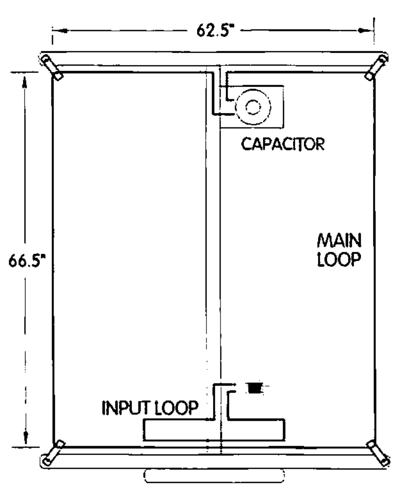

Fig. 1. The 80 meter loop antenna, showing the construction details.

Construction

Insulated house wire (#12 stranded) was used to form the loop. However, a wire loop requires a frame to hold it. I built a simple frame of furring strips designed to put as little wood between the radiating wires as possible. The frame holds the loop, the variable capacitor (240 pF), and the coupling loop firmly in place, yet it is lightweight and easy to reposition. See **Fig. 1.**

The sides of the loop are separate pieces of wire, supported and connected with plastic terminal blocks (Radio Shack™ #274-678). Since bolts and screws hold the frame together and the wire sides are held by the terminal block screws, it is easy to disassemble the whole antenna to move it. The capacitor is mounted on a Plexiglas™ plate screwed to the central support. (A plastic enclosure would be safer, but the plate was quicker.) The actual construction took about two hours.

Looking at the circuit design in **Fig. 2**, you can see the small loop that couples the coax to the main loop. The coupling loop is made of solid insulated #12 wire. This makes it more rigid for easy shaping and positioning. The top of this loop is held by part of a

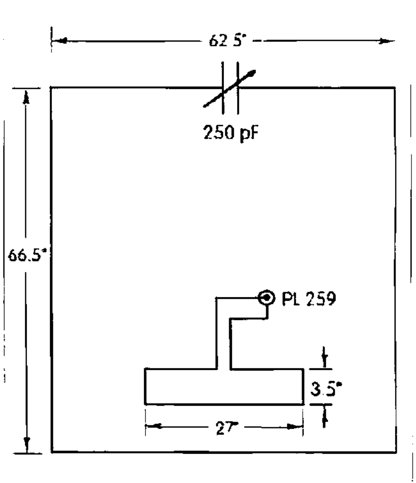

Fig. 2. Loop antenna circuit design and dimensions.

terminal block. The bottom is taped to the main loop itself. The small loop is 27 inches by 3.5 inches.

Operation

The antenna must be tuned to the frequency to be used, by connecting the antenna to a transceiver set for the desired frequency. Turn the knob on the capacitor until resonance is reached. At this point the background noise or signals will be heard, and they will be at a maximum. If the frequency is clear of traffic you can transmit briefly at low power to peak the output, using a field-strength meter. Marking resonance points on the plate that holds the capacitor makes retuning very quick and simple.

By inserting a tuner and an SWR meter in the circuit, the impedance seen by the transmitter can be improved and a wider range of frequencies can be used without retuning the antenna. Only the tuner needs to be touched up if the changes in frequency are not drastic. Recording tuner settings for future use will allow you to leave the tuner in the circuit, set it, and then resonate the loop.

Using an antenna analyzer, the resonance can be found more quickly and accurately without having to transmit.

The antenna sends out maximum signals along the plane of the loop. At the same time there is a pronounced null perpendicular to the plane at its center. These properties can be employed to enhance received and transmitted signals. Also, aiming the null at a noise source can cut down or eliminate that noise. I keep the antenna flat against a wall in an upstairs bedroom. By moving the left side or the right side out, I can easily change direction.

Since this antenna was intended for QRP use, or as much as 10 or 15 watts, the capacitor from an old 300-watt tuner served the purpose. At greater power levels a capacitor with a higher breakdown voltage should be used. Also, much more care should be given to safety considerations.

Comments

It's a pleasure to operate CW or SSB QRP on 80 meters using a relatively small antenna while still getting very good results (not getting TVI complaints is also pleasant, even when the TV is in the next room). The antenna works as well on 30 and 40 meters as it does on 80. Give it a try.

Desoldering

Damage control for the PC board.

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

A lot of paper has been run through the world's printing presses describing how to solder electronic components onto a circuit board. Now, I'm going to tell you how to *unsolder* those same components.

The process of removing solder from a PC board can be as basic as reheating a connection or as advanced as using surface-mount hot air desoldering equipment. Surface-mount parts are not that hard to replace, but most of us don't have access to the replacements needed. For now, let's just keep to through-hole construction. That's what most of us come up against when working on a home-brew project or a kit.

Through-hole desoldering

As the name implies, through-hole desoldering involves removing solder from a hole on a PC board. There are several methods used today, and I've added a few hints and described some kinks I've discovered along the way.

You're building a kit and you have noticed a solder bridge between two adjacent pads. The kit uses a single-sided PC board.

Now, I get madder than Jim Bowie with a dull knife over solder bridges on a circuit board! It only takes a whisker of solder to stop a circuit dead in its tracks. They're so easy to make and so hard to spot! But once you have found the solder bridge, it's usually easy to get rid of.

To remove this kind of solder connection, you can try a few tricks. First, wipe off all the solder on the soldering iron's tip. The tip should be hot, clean and dry. Now, apply heat to *one* side of the solder bridge. In most cases, heating up the pad will cause the solder to wick up the tip of the soldering iron, removing the solder bridge.

If that doesn't work, clean the soldering iron tip again and apply heat to the *middle* of the bridge. Again, the solder should wick up the tip, eliminating the solder bridge.

Here's another variation you can try: Turn the PC board over, so gravity helps the molten solder move towards the soldering iron's tip. Using these methods, you can remove a solder bridge between IC pins and adjacent solder pads without much fuss. However, there are times when you need a bit more help.

"My SBY method really works."

Desoldering braid

Several different manufacturers make desoldering wicks. I use a product called "solder wick." I also have had good luck with Chem-Wik™ brand. Basically, a desoldering wick is a web of fine copper wires braided together and soaked in a chemical flux. As a matter of fact, you can use the braid from a piece of junk coax and some soldering flux to make a hunk of emergency solder wick. To remove solder from a PC board, you apply heat to melt the solder and the braid wicks the molten solder up.

The first step is to determine the proper size of the wick braid. The stuff comes in various widths. Desoldering wick is not a one-size-fits-all product. The thinnest material is great for removing solder between IC pins. The larger width is used for larger and more heat-resistant joints. You can purchase desoldering wick in .030" through .190" widths.

The idea is to heat up the wick and the solder joint at the same time. If you use a wick that is too large, you risk damage to the PC board. Plus, if you've inserted a part backwards and plan to use the part again, too much heat can damage it. Also, too wide a wick will suck up the heat from the iron, making it more difficult to remove the part. I use .062"-wide desoldering wick for most IC pins and quarter-watt resistors.

Let's say you want to remove an IC chip from your circuit board using desoldering wick. Select the proper size wick for the job. If you can, replace the soldering iron tip with one that is wider than it is pointy. You want to get heat to the joint in the shortest time possible. A needle-type iron tip is fine for soldering the part in, but you need something blunt to remove it. Be sure the tip of the soldering iron is clean and dry. You may want to "tin" the tip by melting solder onto the tip and then wiping off the molten solder. Excess solder on the tip will just get sucked into the soldering wick, leaving the solder on the PC board untouched!

Now, put a clean piece of desoldering wick on top of the joint. Apply heat to the joint and in a second or two the solder will melt and be sucked up into the desoldering braid. You may have to repeat this procedure if the joint had an excess amount of solder.

The secret to using desoldering wick is getting the joint hot as quickly as possible. In most cases a 15 watt soldering iron will not have enough "oomph" to heat up the joint, the solder, and the wick. As a rule of thumb, if it takes longer than three seconds to desolder a joint, then the iron is too small or the joint is too large. I keep a soldering iron at my side just for desoldering—a 45 watt iron with a large flat tip.

Tools, tips and suckers

All the examples I've given so far deal with single-sided PC boards. Double-sided PC boards with plated through holes require an entirely different approach.

As the name implies, plated through holes have a layer of copper deposited in each hole on the PC board. This plating is about .003 inch thick and connects the top half of the PC board to the bottom half. For most of us, that's all we'll ever see. However, it is possible to have up to 16 different layers connected to each other by plated through holes. But for right now, let's just worry about double-sided boards with plated through holes.

Unless you're really into pain, using desoldering wick on a double-sided PC board with plated through holes can be a real pooper! The wick will get the solder from the top side. Flip the board over and you can get the solder off the bottom side. However, you'll still have solder hiding inside the hole, clinging to the copper plating.

All right, here's how to get a part out of the PC board without spending a bundle on vacuum-desoldering equipment. Well, actually, there are two ways. The first is my personal favorite: the slash/burn/yank or SBY method.

Resistors are the easiest to remove using my SBY method. Since resistors are cheap, it doesn't pay to save them. So grab your side-cutters and clip one lead of the resistor as close to the resistor's body as possible (you can also just cut the resistor in half). With needlenose pliers, hold the resistor's lead and apply heat to the lead from the *top* side of the PC board. When the solder melts, yank the lead out of the hole.

Now that the leads are out of the board, you need to remove the solder from the holes. This is the second part of my SBY method.

You'll need a stainless steel needle. A needle, not a pin. You'll need something small to hold the needle, and the best tool to use is? Needlenose pliers, of course! From the top side of the PC board, place the tip of the needle on top of the hole. Heat the needle with your high-wattage iron. As the solder begins to melt, push the needle through the hole. Remove the needle. Since the needle is made out of stainless steel, the solder will not stick to it. This opens up the hole, allowing you to install the replacement part.

As simple as my SBY method sounds, it really works. But what about those parts whose leads you can't get to? Crush 'em! For disk capacitors, cut them in half. Use a small screwdriver to pry off the tops of electrolytic capacitors, leaving only their leads. Use slip-joint pliers to crush the bodies of tantalum capacitors.

For ICs you'll need a small sharp side-cutter. At the *body* of the IC, clip off its leads. Now you can remove the pins one at a time. Clean out the holes and install the new IC.

It doesn't take Mr. Wizard to tell you that the parts you remove are history when using my SBY desoldering method. However, there is a certain amount of vengeful pleasure in crushing the dog snot out of a part that took three hours to find!

> ***"Neglecting this simple cleaning step will destroy most irons."***

You always want to apply enough heat to the joint to have the solder flow freely inside the hole. If you don't, you may pull the copper plating out of the holes. You can easily tell by looking at the leads of the part you just removed: If you see a copper ring around the leads, you've pulled the plating out of the hole. With the plating no longer inside the hole, you must solder the top and bottom foils to the component lead of the replacement part. And sometimes you can't get to both sides of the board, so be sure to use enough heat to get the solder molten before you start yanking out the leads.

Super suckers

Using the needle works for small jobs, but it's time-consuming. There are other methods of getting the solder out of a hole.

The cheapest is a desoldering bulb. You squeeze the bulb, heat up the joint and place the tip of the desoldering bulb on the hole. When the solder is molten, you release the bulb. In theory, the molten solder is sucked up into the bulb. In real life, I find, it works better if I *blow* the solder out of the hole from the top side.

Spring-loaded solder suckers work just like the bulb, but are spring-loaded to supply a faster and more powerful sucking action. Alas, these things work even worse for me than the desoldering bulb! I'm sure there are many hams using these things with great success, but I'm not one of them.

Super super suckers!

If you have the money, the best bet is to get a vacuum desoldering station. Usually they come with interchangeable tips and heater elements. Always be sure to check out replacement tips if the price of the iron seems unreasonably cheap.

I purchased a unit with a built-in pump. I chose a Weller model. Other companies, such as Pace and OK Industries, also make desoldering equipment.

Because the desoldering irons have higher wattage heating elements and an instant vacuum they are able to suck the solder out of a hole in a few seconds. It's best to allow the iron to heat up the joint until the solder becomes molten. Then hit the vacuum. In an instant, the hole is clear. Sometimes it helps to wiggle the lead with the iron's tip to make sure the lead is clear from the sides of the hole. They are worth the money if you need to repair double-sided PC boards on a daily basis.

Because of the flux and old solder, desoldering equipment can be a maintenance problem. Be sure you always have gaskets, seals and other necessary replacement parts on hand.

Unlike that old soldering iron, desoldering irons need to be cleaned each and every time they are used. Neglecting this simple cleaning step will destroy most irons. In some cases, if you use the desoldering iron for hours on end each day, you may need to run some thinner through the vacuum pump to prevent the pump from seizing up. Just don't do it with the heating element on!

The best way to prevent damage to a PC board and to find the screwups is to put the right part in the right location the first time. But then you would miss all the fun of troubleshooting your own gear!

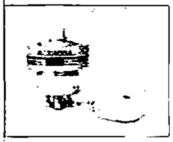
NEW PRODUCTS

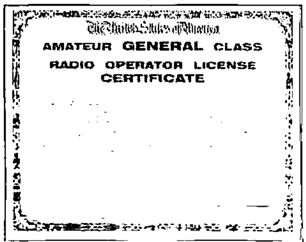
Peaceful Coexistence

Russian manufacturer Svetlana announces the new 4CX400A high performance tetrode designed for linear service. Svetlana's innovative electron focusing and trapping configuration



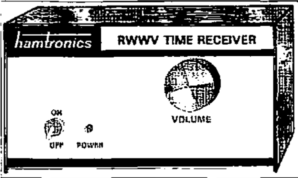
reduces anode secondary electron emission, achieving increased conversion efficiency, with low intermodulation distortion. A single 4CX400A will produce 600 watts PEP at only 2500 volts DC, and three in parallel will conservatively produce the legal limit of 1500 watts PEP and key down CW with bullet-proof reliability.

The inexpensive but rugged Svetlana SK2A ceramic socket is available for use with the 4CX400A tetrode, and together they will withstand severe shock and vibration. Contact Svetlana for technical information and a list of other Svetlana products for amateur radio applications. Svetlana Electron Devices, Inc., 3000 Alpine Road, Portola Valley CA 94028. Phone (800) 578-3852/(415) 233-0429; FAX: (415) 233-0349.



License Certificate

The classic FCC Amateur Radio License certificate is back! Originally issued only to Amateur Extra Class licensees until government cutbacks in the 1980s. FCC-approved certificates are now available for every amateur class. These license certificates have been meticulously recreated and are printed on the same high-quality paper as the originals. They are $14.95. Contact License Certification Service at 800-79-CERTS (792-3787) or on the web at: http://www.quiknet.com/certs.

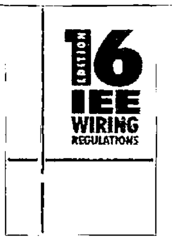


Listen In on the World

Hamtronics, Inc., has just announced a new low-cost dedicated receiver for listening to the 10.000 MHz WWV broadcasts. Don't let its small size fool you—the model RWWV is a very sensitive and selective AM superhet receiver PCB module, crystal-controlled on 10 MHz. Easy to build and align, it's a fun project, even for beginners.

The RWWV operates either on a 9-12 VDC power supply or a 9V battery. It has a 50Ω input so you can connect it to any type of HF antenna, and it's so sensitive you can get good reception with just a small length of wire or an indoor whip antenna. And the complete kit is only $89! You can also get a kit to build just the PC board module for $59, or buy the unit factory-assembled in a cabinet with speaker and AC power supply for a very reasonable $129.

For details, write to Hamtronics, Inc., 65-D Moul Rd., Hilton NY 14468-9535, or call (716) 392-9430; FAX (716) 392-9420. Be sure to tell them where you found out about the RWWV, and while you're at it, ask for a complete catalog.

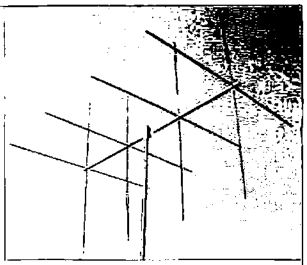


When You Have To Wire

We hams, being experts with electricity, can get drafted to deal with electrical wiring. If (or when) *you* do, you're going to need to know something about wiring regulations. For $29.95 you can invest in Brian Scaddan's *16th Edition IEE Wiring Regulations*, from BH Newness. 96 pages of everything and a half you need to know when dealing with the 120-volt monster.

New from the Cubex Hive

Cubex's new sideband antenna, the "Queenbee," is a 6 meter 4-element pretuned quad antenna, all Fiberglas™ construction with a heavy-duty aluminum mast-to-boom coupler. The Queenbee is fed directly with 52 ohm coax and features Cubex's exclusive tuning block, which allows the antenna resonance point to be adjusted slightly without completely changing the wire elements. Plus, the "Queenbee" comes with the driven element premarked for a resonant frequency of 50.2 MHz, giving the antenna a bandwidth of slightly less than 1 MHz at an SWR of less than 1.7 to 1.



The Queenbee is easily assembled and adjusted, but the best feature is the price: only $159.95 plus s&h. For more information, contact Cubex, 2761 Saturn St., Unit E, Brea CA 92821. Telephone (714) 577-9009); FAX (714) 577-9124.

EDX-2 Automatic Antenna Tuner

Alinco Electronics' new EDX-2 is designed to provide a quick match between antenna and transceiver, with the ability to match a length of antenna from eight to 80 feet, on bands from 10 to 160 meters (a minimum antenna length of 40 feet is required for 160 meter operation).

The EDX-2 uses computer logic to operate a network of capacitors and inductors to find the combination presenting the lowest possible SWR to the radio. Mobile users have added flexibility in using an eight-foot whip when in motion, or adding a length of wire to the stationary whip to improve HF operating performance.

The EDX-2 comes equipped with a control cable interface designed to plug directly into the Alinco DX-70 HF radio, but the unit can be adapted for use with other manufacturers' radios. It is enclosed in a weather-resistant case, suitable for use in mobile, base and marine operations, and can be operated in a horizontal or vertical position.

The suggested list price is $344, but check with your dealer because you may be able to pick up this briefcase-sized unit for less.

For more information, contact your dealer or Alinco Electronics, Inc., 438 Amapola Ave., Ste. #130. Torrance CA 90501. Phone (310) 618-8616; FAX (310) 618-8758.

Two Pocket-Size Winners from SGC

SGC, "the SSB people," announce the publication of two new HF-SSB-oriented books: *Go Mobile at 500 Watts* and *DSP: Facts and Equipment*.

Go Mobile has chapters on the basic layout of a mobile system, on power for a 500-watt mobile system, antennas and grounds, noise and vibration, and on installation, with instructions based on SGC's own technicians' experiences in four specific vehicles—but their tips can be applied to any manufacturer's high frequency gear.

DSP is an education in how sound is recorded and reproduced, on the comparison of analog to digital filtering, on DSP in high frequency communications, and on the future of DSP.

Both books are available (suggested retail price $19.95 each) from ham dealers and from SGC, Inc., P.O. Box 35326, Bellevue WA 98009. For more information, call the SGC Marketing Department at (800) 259-7331.

Atomic Keyer from Embedded Research

'A lot of BANG! for your thirty bucks.

Marshall G. Emm AAØXI/VK5FN
2460 S. Moline Way
Aurora CO 80014
75230.1405@compuserve.com

As we used to say in the Air Force, close doesn't count, except in three sports: horseshoes, cowpie fights, and nuclear war. For us old Cold Warriors, it's a huge relief that nuclear war is less likely with every passing month. But we must still be vigilant—any nuclear detonation could send us back to the Stone Age of radio, and we Morse operators may have another heyday. I, for one, will be prepared, because I have an Atomic Keyer from Embedded Research. The AK comes close to being the perfect keyer for field and emergency operation.

No, the Atomic Keyer is not nuclear-powered. As far as I can tell it isn't even radioactive, though it will certainly help you to be "radio active." The AK-1 is a $30 kit which lets you build the least expensive memory keyer on the market, with a surprising number of features and specs, all the result of clever PIC programming. The catchy name comes from the secrecy surrounding its development by designers Gary Diana N2JGU and Brad Mitchell WB8YGG. They began working on the project early this year, and QRP guru, Bob Gobrick VO1DRB, asked them what they were working on: "...some kind of atomic keyer or something?" The name stuck.

"The least expensive memory keyer on the market, with a surprising number of features and specs."

By the time Dayton rolled around, the project was finished. A prototype had already been reviewed electronically on the QRPer's Internet lifeline, QRP-L*. Brad and Gary sold most of their first production run at Dayton, and a bunch since, mostly via mail-order and their Web home page: http://www.vivanet.com/~gmdsr. I mention this because the timing is amazing—from concept to packaged kits in about three months—and we're going to see a lot more of this in the years to come!

The Atomic Keyer features two static memories, two dynamic memories (total 64 bytes), a piezo transducer for audio output, switchable send/practice/tune modes, and variable speed iambic keying with standard 1:3 weighting. Current consumption is very low—typically around 300μA when idle and about 1mA key-down when operated from a pair of AA batteries—giving a useful battery life of about six months under normal operating conditions. Because the power requirements are so modest, no on/off switch is required (or supplied), but I added one for reasons which will be discussed later. As supplied by Embedded Research, the AK-1 kit includes everything you need except for a power source (3-5V supply, e.g. 2 AA or AAA cells), battery holder, and an enclosure.

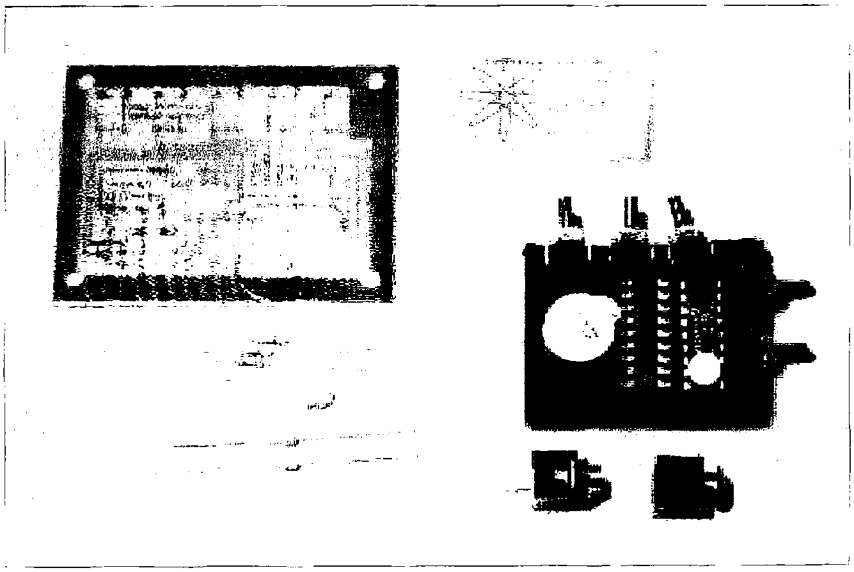

Photo A. Can you tell just how tiny the whole kit is?

Construction

You might be a bit surprised to find the kit supplied in a 6- by 9-inch catalog envelope, and you'll be astounded to find that the board and all the parts are in a tiny brown envelope. Apart from the board itself and the five push-button switches, there are only 10 components, including the microprocessor chip!

All of the components except for the (supplied) jacks for paddle and key-line are mounted on the circuit board, which measures about 2 by 2.75 inches.

Step-by-step instructions are included, and a builder with modest skills will have no trouble completing the project in less than an hour. The PIC16LC58A is an 18-pin CMOS device, so you want to be careful with its installation and handling. It is socketed, so you should leave insertion until everything else is done, and take the usual precautions against static when handling it. Soldering the pins on the IC socket is the only tricky assembly step. The solder pads are very close together, so it would be a good idea to solder under some sort of magnification and check each connection very carefully.

The instructions go into quite a bit of detail regarding the installation of the push-buttons. Read that part carefully, and do some measuring before you install the buttons! Theoretically, the buttons can be soldered directly to the component side of the board for mounting through a panel that is 1/8-inch thick. I took them at their word and found, to my chagrin, that there was not adequate clearance. One limiting factor (which was probably too obvious to mention in the instructions) is the height of other components—make sure the IC socket is mounted flush with the board, and that the chip itself is fully inserted. The switching transistor, Q1, also needs to be mounted as low to the board as possible. The manual gives you instructions for three optional mounting methods—shimming the buttons, mounting them on the foil side of the board, and remoting them.

I installed the completed keyer in a small plastic box (RS270-222), mounting the board and the jacks on the lid of the box. That was the point at which I found that the buttons didn't protrude enough for operation. Since the box is plastic, I found that I could create a single elongated hole surrounding all five buttons, allowing them to be depressed. That seemed easier than removing the buttons from the board and re-installing them on the foil side or shimming them. The box has room for an AA battery holder (RS270-382) and when finished, it's just a little blue box with two tiny jacks and five buttons on the top. You may want to use a metal box to suppress RFI generated by the microprocessor, but it was not a problem in my test environment.

If you hate batteries, it would be a simple matter to add a power jack or pigtail power lead, and, of course, a 5V regulator between any higher voltage supply and the existing +3-5V terminal on the board. A 7805 (RS276-1770) will do just fine.

There is a 10k resistor network, which is a component I hadn't seen before. I mention it because the little bugger is *fragile*. Handle with care, because a replacement won't be easy to find at your local parts store!

Although it isn't strictly necessary, I added a power on/off switch in the positive line from the battery holder. I did this because it is occasionally necessary to clear the keyer's memory, and it's a nuisance to open the box and disconnect the battery. Note that the dynamic memory in the AK-1 is volatile; that is, anything you have stored will vanish when power is disconnected. I don't see this as a problem since it's basically a CQ memory anyhow—it only takes a couple of seconds to re-record your callsign and optional second message.

The smoke test

The keyer essentially tests itself! As soon as you connect power to it, you will hear "AK 1" sent through the piezo audio output. There's not much that can go wrong, and if you hear the sign-on characters you are probably in business. If not, take another look at component placement and examine the solder joints. And if you still have trouble, Embedded Research is only an E-mail away.

Operation

Keying is clean and precise. As with all keyers, it will take a bit of practice to get used to the AK-1's "personality" or "feel." The ability to put the keyer into "practice" mode is great when you are first getting used to it.

The five buttons have the following functions:

1 send CQ CQ CQ DE DM1 DM1 DM1 K
2 send DM1 DM2
3 send DM1
4 send DM2
5 Set Speed: dits down, dahs up
1&3 Input DM1... Press 3 to finish
3&5 Input DM2... Press 3 to finish
1&4 TUNE Key output, stop by hitting paddle or button 4
2&4 Toggle On Air / Practice modes

DMn represents the two dynamic memories, in which you can store message text and/or your callsign. Where functions are shown with two button numbers separated by the "&" character, you need to press both buttons simultaneously to enable the function. An undocumented combination, 4&5, makes the keyer report its software version (v1.22 in the unit reviewed).

Memory usage is a bit unusual, in that the AK provides two dynamic message memories (you can load characters into them) and two static memories. The first static memory sends a standard 3 x 3 CQ call and when you send it, the AK will plug in your callsign from the first dynamic memory. The second static message will send the first dynamic message

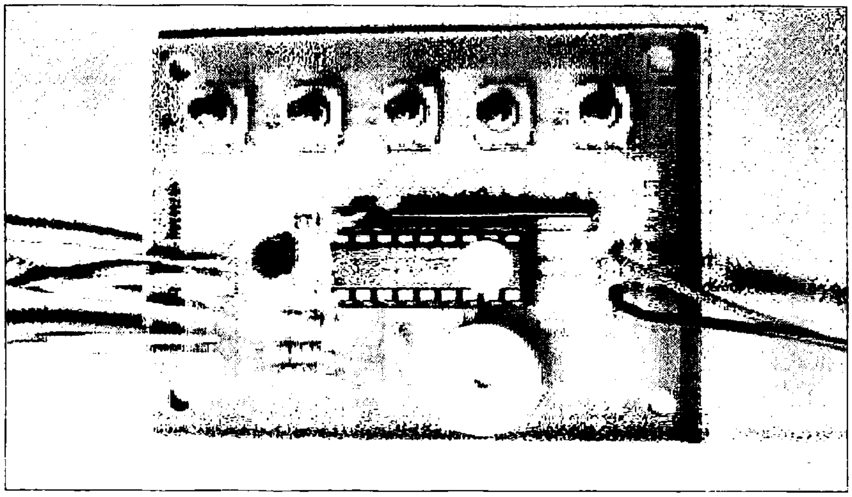

Photo B. Interior view of the Atomic Keyer.

immediately followed by the second dynamic message. Personally, I think it would make more sense to go with dynamic message memories only, because I often use something other than a standard 3 x 3 QSO—I usually end a CQ with AR or AR K rather than just K; of course, once in a great while I like to call CQ DX!

The speed setting is also a bit unusual, and not adequately described in the instructions. Pressing button 5 puts the keyer into speed setting mode, after which speed is increased by holding in the dah paddle, or decreased by holding in the dit paddle. You hold the paddle in until the keyer reaches the desired speed, then release it. If the rate of increase or decrease is too slow for you, you can "bump" it along by tapping the opposite paddle (without releasing the one you are using to change the setting). It seems a little odd at first, but you easily get used to it and of course it obviates the need for a speed control pot.

Conclusion

The Atomic Keyer is an excellent little kit, representing very good value for the money. It's unlikely to replace my CMOS-III for day-to-day use in my shack, but on the other hand, it cost less than half as much and it will be great for field and mobile work. Gary and Brian are very amenable to suggestions, and indications are that the AK-1 will be upgraded as users supply useful feedback. One of the great benefits of programmed keyers and PIC technology, as compared with, say, the 8044, is that an upgrade will be just a matter of popping in a new chip.

Availability

The AK-1 Atomic Keyer kit comprising circuit board and all board-mounted components is available for $29.95 (+$3.95 shipping/handling) from: Embedded Research, P.O. Box 92492, Rochester NY 14692. E-mail: gmdsr@vivanet.com.

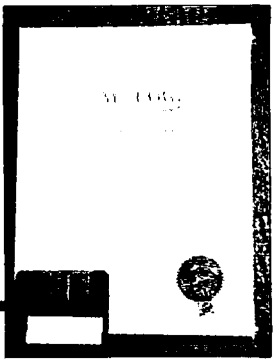
73 Review

M★LOG Logbook Program



It doesn't get much easier than this!

Larry Feick NFØZ
3333 W. Wagontrail Dr.
Englewood CO 80110

Call me Ishmael. Oops, wrong story! Call me old fashioned. I believe in CW, I believe in tradition, and I believe that amateur radio operators are ladies and gentlemen. I also believe that the first and only purpose of amateur radio is communication; anything that gets in the way of communication is bad, and anything that facilitates it is good. If that makes me a curmudgeon, call me Wayne Green!

For years I resisted the idea of computerizing my logbook, mostly because the logging programs I ran into were cluttered, clumsy, and had a tendency to force me to change my logging and even operating habits to suit the program. Surely it should be the other way around, I thought—computers are supposed to help people by taking over part of the workload, not add to it!

I was reasonably happy with the system I had; a paper system that worked, and worked well, and I really didn't need a computer to do what I wanted to do. Besides, most of the logging programs that I have seen are either highly specialized for specific interests (like contesting), or are designed by hams who have no idea how to write a good computer program.

So when I was asked to review M★LOG, from Milestone Technologies, I had mixed feelings. I expected the process to be a waste of time and effort, and expected to continue doing things as I have always done them. Well, it *wasn't* a waste of time, and the great news is that this is a computer program that not only allows me to continue doing things the way I have always done them, much more efficiently, but adds a whole new area of possibilities.

From the moment you open the box, you see that M★LOG is different. The manual is comprehensive and well written, and installation is a snap—just put the disk into the drive and type INSTALL. Unlike so many programs lately, this installation program tells you what it is doing and gives you some options, such as where the program will be installed. There are also facilities for updating from earlier versions, and for importing log data from other programs (and for exporting data in several different formats).

As with any computer program, there are three key questions:

(a) What data can be stored (what goes in)?

(b) What can you do with the data once you've got it into the program (what comes out)?

(c) How easy is it to use?

"At the touch of a couple buttons I can see how many countries I've worked, and how many are confirmed."

Data

QSO records in M★LOG are stored in "tables," which you can think of as being an electronic log book. Just as you can have separate logbooks for different purposes, you can have multiple log tables. I ended up creating a universal "main" log, supported by separate temporary tables for specific purposes, such as the local QRP club's contest. That allowed me to look at the contest log separately and produce a printed log and QSL card labels, but I was also able to copy the contest entries into the main log so that I could have those QSOs included in my index of stations worked, and some statistical studies that I do from time to time. M★LOG allows you to establish an unlimited number of such logs.

The QSO data to be stored is a problem area with many logging programs. There are some aspects of a QSO which you will always want to record: callsign, name, location, date, time, band, mode, and QSL card sent/received. Beyond that, logging requirements depend on how you operate and what your goals are. Some people will be primarily interested in contests, others in awards, and so on. In fact, it's probably fair to say that no two hams will have identical logging requirements. Attempting to cater to everyone's needs requires either a lot of fields, or a lot of flexibility.

M★LOG's approach to this problem is to offer a flexible record structure in which the standard data items are predefined, along with some "nearly standard" things like text comments (recorded in three individual fields, or an associated text file of unlimited size), country (from a prefix table that you can edit and update) and fields to describe your "operating conditions" (rig, power, antenna).

But, this is where this one really shows its power—in addition to the data described above, you can actually define six separate fields for whatever purposes you want. When you first start using the program, two of these six fields are set up for states and counties, but you can redefine them if you want to. I've left those in place and defined a field for grid square, and left the other three for "ad hoc" requirements such as specialized contest exchanges. There are so many things that people track these days! A few examples are Regions, Zones, 10-10 numbers, club member numbers, power levels, IOTA numbers... the list goes on. And if you need more than six of these, no problem: M★LOG will let you create a duplicate table with six more definable fields, and so on.

The thing is, each of these user fields is indexed and reportable, so at the touch of a couple buttons I can see how many counties I've worked, and how many are confirmed!

On the other hand, you don't *have* to use any fields except for the callsign, and according to the manual, unused fields do not occupy any space on your disk!

Also, at the touch of a button, you can consult a CD ROM callbook and plug the relevant information into the QSO record (and also print out a mailing address to a text file). QRZ!© and Amsoft© databases are directly supported, and others can be used with a bit of configuring.

The bottom line is that if you can write it down on a paper log sheet, you can store it in M★LOG.

Getting it back onto paper

There are four basic types of data output you might need from your logging program:

(1) Look up and display a record on the screen.

(2) QSL data in the form of cards, labels, or data for use in another program.

(3) Actual logs, for contest entries and award applications.

(4) Data analysis, including an index of every station you have worked, activity by band and mode, or whatever it is you want to look at.

All of these are well supported, and again the program goes beyond the basic requirements and offers virtually infinite flexibility.

When you want to look up a callsign, you can select from a list ordered by callsign, date/time, or several other ways, or you can input a callsign or partial callsign. Either way, M★LOG looks to be very fast. I installed it on a 386, and with about 2,000 QSO records loaded into the program an individual callsign was found almost instantaneously.

QSL data can be printed in a standard label format, and you can modify the label specs to match whatever stationery you have. You can also output QSL data as a text file, as a delimited data file, or as a WordPerfect© secondary merge file. These formats allow you to pick up the data with another program to do the actual printing. For example, if you have enabled the external callbook facilities, you can output data allowing WordPerfect to print the data block on one side of a QSL card, and an address and other messages on the other side—resulting in a mailable postcard.

An advanced feature of both log and QSL printing is the ability to prepare output from a template that you design. The template is an ASCII file which you prepare with a text editor or word processor. In the template file you can include both literal text to be printed and also specify fields from the QSO record and where they are to be positioned. I found this feature is very handy when preparing contest logs, because it allows you to specify the contents and order of columns in the report.

Probably its most powerful feature is the ability to specify logical constraints for reports and on-screen selection lists. Requests are framed in a language which will be very familiar to users of dBASE and similar programming languages. An example of use would be something I did the other day; I requested a list of all confirmed CW contacts on 40m with DX stations where the other station and I were both operating QRP

But how do you drive it?

For all its power and flexibility, M★LOG is very easy to use. The program starts with a nice graphics screen, and the characters "ML" are sent, in Morse, from the PC speaker!

All of the various logging, reporting, and utility functions are organized in a rational manner, and the menu selections reflect the tasks in ways that are familiar and easily understood. Screens are nicely laid out, not cluttered with an excessive number of data fields, and you can move around easily with the keyboard or a mouse. Whenever the cursor is in a data field, there is a message at the bottom of the screen explaining what the field is for, and further help is available by pressing Function Key 1.

When you are entering QSO data, you can select from a number of "QSO Profiles" to provide some of the data automatically. I set up a profile for each combination of rig and antenna that I use, so I don't have to type in the information each time. And some fields are carried forward from one record to the next—fields like the band, mode, time and date, which often require only a minor adjustment. You can even set up your function keys to put specific information into specific fields.

The contest mode offers two optional methods, abbreviated and full record. In the abbreviated mode, it automatically generates serial numbers, and puts the current time in (calculated into Zulu from the PC's clock) when you press the Enter key. In the full screen logging mode, you have access to all of the data fields, so you can use your own defined fields for oddball contest exchange information like power level, member number, or first name.

"Dupe" checking is almost instantaneous, and unlike some contest programs you can continue and log a dupe. This feature is handy if you made the contact before you were able to report it as a dupe, or if there are contest rules that say, for example, dupes are OK if a certain time period has elapsed. The important thing is that it shows you all previous contacts with the station and allows *you* to make the decision!

You don't have to be a computer expert to install and use M★LOG: the basic functions are done just the way you would do them on paper, and the manual makes it easy to figure out how to do more elaborate tasks later.

What's missing? Things that I, for one, don't want! It doesn't have a keyer built into it, it doesn't directly control my transmitter, and it doesn't have predefined contest logs that need to be updated every year when the rules change. And only two of the more popular CD ROM callbooks are directly supported. If those features are critical to you, you can either use another program or write to Milestone Technologies and complain about how old-fashioned *they* are!

Wrapping up

I can say without hesitation that this is the best logging program that I have ever used, and it opens up a whole world of possibilities in analyzing my log data going back over 20 years or so. When you factor in the price (lower than most packages I see advertised) it becomes a bargain, too. M★LOG Radio Logkeeping System Requirements: Any DOS PC running DOS 2.10 through Windows 95™. Hard disk recommended.

Milestone Technologies, 3140 S. Peoria St. Unit K-156, Aurora CO 80014; (303) 752-3382. Credit card orders (Visa/MC/Disc/Amex) 800-238-8205. Price: $39.95 + $5.00 s/h in US and Canada.

A Simple QRP Wattmeter/Dummy Load

OK, how many countries have you worked with 5W?

J. Frank Brumbaugh KB4ZGC
Box 30 - c/o Defendini
Salinas PR 00751-0030

Ham QRP operation is a rapidly increasing interest and the number of commercial kit transceivers, transmitters and receivers is increasing proportionately. While many kits are designed for CW operation only, more are being offered which are capable of SSB as well.

The most important thing about QRP operation, and the main reason for its burgeoning popularity, is that it works! A lot of hams with QRO stations, having tried QRP, are amazed that Q5 QSOs are possible worldwide using just 5 watts or less. And they are intrigued by the challenge of chasing awards at QRP levels, awards many have already earned using high power.

A further reason for the enthusiasm for QRP is that many hams live in condominiums, apartments and small-lot subdivisions where high power is guaranteed to interfere with the multitude of nearby consumer electronic equipment. Switching to QRP generally eliminates interference without reducing the enjoyment of operating on the HF bands.

QRP is widely accepted as meaning a maximum of 5 watts PEP or less RF output to the antenna. Therefore, QRP enthusiasts are very interested in *knowing* the level of RF their rigs are putting out. The combined RF wattmeter/dummy load described here (**Fig. 1**) is designed to measure power levels between 1 and 6 watts of RF, to provide an overlap beyond the 5-watt level. In addition, the RF levels below 1 watt are not displayed, enabling the most important 1- to 6-watt range to occupy about 95 percent of the meter scale. This instrument is easily calibrated with a variable DC voltage of about 9 VDC to just over 25 VDC, monitored with a DMM to assure voltage accuracy.

"Switching to QRP eliminates interference without reducing the fun of HF."

The circuit

RF applied to J1 is dissipated by the dummy load resistor Rx. The peak RF voltage developed across the dummy load is rectified by D1, filtered by C1, and applied through meter multiplier resistor R1 to meter M1, which is bypassed for RF by C2. However, zener diode D2, between D1 and R1, prevents the passage of rectified voltage when the input power level is less than about 1 watt. Thus, only rectified voltage from power levels between 1 and 6 watts RF will be indicated on the meter.

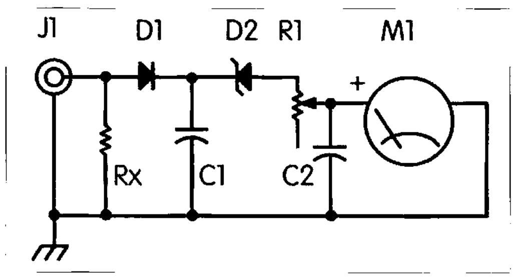

Fig. 1. Schematic for the QRP wattmeter/dummy load.

Because of the relationship between RF power and peak voltage across a known resistive load, the voltage variation is nonlinear, and is much more rapid at very low power than at higher powers. Measured on a meter, the change in rectified voltage from 0 to 10 volts (the equivalent of 1 watt) would take up the lower 40 percent of the meter scale, leaving only the remaining 60 percent for the power span from 1 to 6 watts. Using the zener diode to suppress this unwanted power range results in the 1- to 6-watt range using over 90 percent of the scale.

The calibration mark at 1 watt will be slightly above scale zero on the meter. Full-scale will represent 6 watts. The scale will still be somewhat compressed at the high end, but this is unavoidable.

Calibration

First you calibrate your meter. **Fig. 2** shows the setup for this. A source of filtered 9-25 VDC is needed. A DMM should be used to check the accuracy of the calibration voltages.

To maintain maximum accuracy, the meter must be calibrated using the same parts that will be used in the final instrument. With the parts tacked together and the meter face removed to expose the scale so calibrations can be made with a fine pen, and with R1 set to maximum resistance, gradually apply DC voltage at the input until it reaches 24.49 volts. Then adjust R1 so the meter needle rests at full scale. Mark this point "6."

Then lower the input voltage to 22.36 volts. Mark the point where the needle stops "5." This should be marked in red, if possible, as a reminder not to exceed the QRP maximum RF level of 5 watts.

Continue reducing the input voltage and marking the meter scale as follows: 20 volts, 4W; 17.32 volts, 3W; 14.14 volts, 2W; 10 volts, 1W.

An alternative method of calibration is available if you have access to an accurate low power wattmeter. Simply connect the wattmeter in line with a transmitter and the wattmeter/dummy load. Adjust your transmitter for the same power levels listed in the above paragraph, as measured on the known-good wattmeter, and mark the corresponding level on the face of the wattmeter/dummy load.

This completes the calibration. Replace the meter face, untack the components and proceed with construction.

If you are unfamiliar with the disassembly of meters please see "Use Those Surplus Meters," *73*, January 1992, page 42.

Construction

This instrument must be constructed in a shielded enclosure. An aluminum box or a case made of printed circuit board material is ideal. The meter size will dictate the size enclosure required. One of the small surplus edge or square plastic meters originally made for home entertainment equipment or CB radio, most of which have approximately a 200 µA movement, will allow compact construction. (I built mine in an LMB OOZ aluminum box which measures 2-3/16" x 2-1/8" x 1-3/4". The SO-239 on top almost makes it look top-heavy!)

"Lots of hams are amazed that Q5 QSOs are possible worldwide using 5 watts or less."

The dummy load uses six 300-ohm 2-watt 5% carbon film resistors (Mouser No. ME 262-300), connected in parallel. Ocean State Electronics carries 2% 2-watt film resistors, but not in 300-ohm value. However, a 270-ohm and 330-ohm resistor in parallel is equivalent to two 300-ohm resistors in parallel.

I chose to make my internal dummy load by bundling the six resistors together and soldering them in parallel at each end. I chose 12 watts rated dissipation so the load would just loaf along when dissipating 5 watts or less.

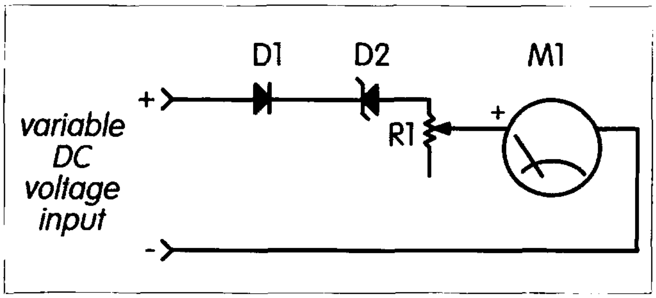

Fig. 2. Calibration setup.

Depending upon the size of the enclosure and the room remaining after mounting the meter, the dummy load resistors can be bundled together tightly, although this reduces the safe maximum dissipation rating. You've got 5 watts of heat you have to dissipate, somehow.

Operation

Because this instrument contains a permanently wired dummy load, it is intended solely to be used either to measure RF output from your QRP transmitter or to allow setting your rig for a specific output power before connecting the rig to your antenna or tuner.

Connect J1 to the antenna connector on your transmitter. The RF output power will be indicated on M1. If you can vary the output power from your rig you can easily set it for any desired power output between 1 and 5 watts. 73

Parts List

C1, C2	0.01 µF ceramic disc
D1	Germanium diode, 1N34, 1N60, 1N90, 1N270, etc.
D2	9V 400 mW zener diode
J1	RF connector, builder's choice
M1	Microammeter, 200-300 µA (see text)
R1	Meter multiplier trimpot, 150k Ohms
Rx	50 Ohm dummy load, home-brewed, see text

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

Over the last few months we have been examining some basic concepts of radioteletype. This has been in response to a number of you who have written with the message, "Hey, I just came in. What's all this RTTY stuff about, anyway?" To date, a glossary of terms, fundamentals of character encoding, and methods of digital transmission have been covered. This month the series concludes with techniques for consummation of information intercourse.

Although there are several specialized ways to transmit digital data, this column will take a look at the three major ways of moving information this way, through conventional RTTY, AMTOR, and packet.

Conventional RTTY

Conventional Baudot, or Murray, RTTY allows transmission of data from sender to receiver, one way at a time. This is often termed "half duplex" communication. As we saw last month, the bits are sent sequentially, each character composed of a START pulse, data pulses, and a STOP pulse. In a RTTY transmission, the transmitting station sends data straightaway, nonstop, until the data stream is reversed, sender becoming receiver, receiver becoming sender.

For a classic RTTY station, data rates typically are 45.45 baud (bits per second), each data pulse lasting about 22 ms. Let's forgo some of the intricacies for right now. That means that a noise pulse would have to last a substantial time, perhaps at least seven to 12 milliseconds, to destroy a data pulse. Nonetheless, a nearby signal can take out letters, or groups of letters, with abandon. Unless the receiving operator questions the integrity of the transmission, errors in data exchange will neither be caught nor repaired.

AMTOR

Contrast this with AMTOR, in which seven-level code, a special AMTOR code, is transmitted at 100 baud. Here, each data pulse is only about 10 milliseconds. Consequently, a much briefer burst of noise can "take out" a data pulse, rendering that character so much garbage.

> "With AMTOR, erroneous groups are not displayed, they are dumped into that great bit bucket in the sky!"

So on the surface, as it is set up, you might get the impression that AMTOR is a much less reliable medium than Baudot for RTTY transmission. Not so fast, Kemosabe! Recall that Baudot RTTY is transmitted one way at a time, with the sender's brain responsible for filling in missing characters. Thus, if you are looking at a line which says, "TO ALL STJTIONS," your brain has little trouble realizing that the third word should be "STATIONS," particularly if I tell you that the Baudot codes for "A" and "J" differ by one bit. So monitoring a Baudot transmission is no problem. Everyone expects "hits" now and then, and you develop the knack for reading through them.

But with AMTOR, we will ask the system to do this for us. So, each character must meet certain bit matching criteria (let's forgo the details here, too) to be valid. And groups of characters containing an error are as invalid as random noise.

Erroneous groups are not displayed, they are dumped into that great bit bucket in the sky! Thus, if you are just monitoring an AMTOR conversation and receive a group of characters in which the character check does not compute, your receiving setup will toss it away, and you will never see it on the screen. Since you are not in communication with the sender, and thus have no way to re-request transmission of the group in question, it is lost forever. While there are one-way, or broadcast, modes of AMTOR which build in enough redundancy to allow for a certain number of hits, they are not typically used in contact type settings.

Allowed to operate as designed, though, AMTOR allows for virtually flawless transmission. With a noise-free circuit, the rates of data transmission can approach the maximum data rate being sent. With interfering or noisy signals, the receiving station will recognize the errors in transmitted information bundles and re-request transmission of that data. Under such conditions, the many retransmissions can slow information exchange to a crawl; but the data *will* get through, and get through perfectly.

Packet

Where AMTOR operates on a morsel of a few characters at a time, there is another technique that takes a different approach to error correction. Called "packet radio," this scheme organizes the data into discrete packets which have integral addressing and error-checking information, much as the XMODEM protocol used for computer program exchange. Each burst of data, called a "frame," contains:

- •An opening flag byte
- •An address field containing the address of the originating station, ultimate addressee, and any repeaters required in between
- •A control field which identifies the type of data contained in the frame
- •An information field containing up to 256 bytes of data
- •An error-checking field using the Cyclic Redundancy Check
- •An ending flag byte

These packets are sent by FSK or AFSK as fast as systems allow, with some work done on the air at 9,600 baud. In many areas, penetration of packet is such that information of some sort is always flowing through the ether!

While each of these techniques would appear superior in some way, whether simplicity, reliability, or speed, each has its champions, and each is "best" under a given circumstance. I look forward to hearing from readers as to how you all are using these, or other, techniques to move data. I should add that while conventional RTTY is limited to alphanumeric data, packet just moves packets of data. Those packets may assemble into text, graphics, sound files, or graphics, making this transmission technique invaluable to the transfer of complex information in this digital age.

> "Packet can transmit text, graphics, sound files or graphics, making it invaluable in this digital age."

In fact, the packet switching network that forms the heart of the Internet and the World Wide Web is only a slightly different form of the transmission technique used for amateur packet radio. Since we started RTTY with machines scavenged from commercial service, I guess we could say, "What goes around, comes around." Or at least LOOPs around! Lots of you have been logging in to the RTTY Loop Home Page, where back columns are available, as well as lists of programs available in the RTTY Loop Software collection, and many, many sites of interest to the radio amateur on the World Wide Web. Check it out yourself, at http://www2.ari.net/ajr/rtty/. Let me know what you think, and what you are interested in seeing in future columns, by snail mail to the post office box, or via E-mail to me at ajr@ari.net, or on America Online at MarcWA3AJR, or on CompuServe at 75036,2501. Above all, let me hear from you! 73

NEVER SAY DIE

Continued from page 13

The information on how to care for your body is available, you just aren't going to find it in the medical books. Just as you fight change, whether it be the code test, at your work, getting serious about dieting, etc., doctors tend to stay with what they learned in school. They don't spend much time keeping up. That might louse up their golf days or fun times spent at medical conventions (more golf). Yes, I'm cynical. I'd be less cynical if America wasn't down near the bottom in health among developed nations.

Ignorance Is Bliss

Sure, as long as you can be blissful when you are both poor and sick. A lack of skills and knowledge dooms one to either a career in crime or a non-demanding, low-paying job with little future. Ignorance of maintaining the body means chronic illnesses such as diabetes, arthritis, multiple sclerosis, Lyme disease, back trouble, heart attacks, glaucoma, cancer, AIDS, and so on. That's bliss?

Publishing Technology

Technology sure has changed publishing over the last three decades. When i started *73* in 1960 I would get typewritten copy from the authors. I'd then edit this with a pencil, using standard proofreaders' notation, and send it to the printer to be set in type. I'd picked Morton Press, in downtown Manhattan, a 60-year-old printing company that specialized in magazines.

The type was set on old Mergantheiler Linotype machines using hot lead. They'd ink the trays of type and send me galley proof strips for proofing and to paste up into page format. The photos, schematics, and other illustrations were sent out to be made into halftones and came back as thin copper sheets stuck on wooden blocks the same height as the lines of type. I would then cut the galleys and proofs of the illustrations to fit the pages and send these "pages" back to the printer to have the type and illustration blocks clamped together to print the pages. They would then correct any typesetting errors (often making more errors in the process), put the pages together and send me a proof of the assembled pages.

The last two or three days before press time were hectic, requiring me to be at the printer's plant to make last-minute corrections and then correcting the errors made in making the previous corrections. Printers had special rooms set aside for the editors to do this last-minute work.

Today most articles arrive in disk form and I edit them on my computer. The photos are scanned in by computer. The schematics are drawn by computer instead of by a draftsman. Then the copy and illustrations are put together in the computer and the finished page printed out on film for offset printing.

Continued on page 50

NEVER SAY DIE

Continued from page 49

When I was starting *73* I had to buy a stencil addressing system and a mimeograph. The addressing system used paper stencils which had to be softened with water before typing. There was a stencil holder that clamped on the typewriter platen, and typewriters had a stencil position that pushed the ribbon out of the way. The typewriter then cut the softened paper. The stencil printing machine weighed in at around 600 pounds. I'd stick stacks of the stencils into one side and it would slide them under an inked roller and print the address. At magazine mailing time I'd have to sit there for hours feeding magazine wrapper papers under the stencil printing area. Then I'd drive the cartons of wrappers to the printer in Norwalk, Connecticut.

How did I get *73* started? Well, I didn't have much money, so I first sent letters to every ham club I knew of, asking for subscriptions. I also wrote to all of the ham radio stores, suggesting they carry the magazine on their counter. By selling my boat, plane, and a Porsche I got just enough money to print 10,000 copies of the first issue. Around 300 stores ordered copies, plus I had around a thousand paid subscriptions. By the third issue my 10,000 print run was too little and I ran out of copies to sell as back issues. Within two years I had over 850 ham stores selling the magazine and the subscriptions were pouring in.

Having edited *CQ* for five years, I knew all of the ham authors, so I asked them to consider my new magazine when they were writing construction articles. Despite all my travels the year before, when I was fired from *CQ* I had five whole issues completed and ready to go. Their new editor, outside of getting bogus ham tickets for the *CQ* staff, had little to do. When it finally came time for him to do some work he couldn't do it and he was fired.

The *CQ* publisher wanted to stop running construction articles and just run columns, so my old authors had no choice but to turn to *73*. They, understandably, wanted to get paid something for their work, and *QST* paid nothing except prestige for their articles, so I had the first choice on most construction, theory and product review articles.

Just 13 years ago, when I was forced to sell my whole magazine empire to one of the megapublishers (or else!), I started over. At that time it cost me over $500,000 for the latest in a computer publishing system. Now, for under $1,000 you can do almost as much as we could with that half-million-dollar system. A used Mac PowerBook© and a used laser printer and you're in business. I still do some of my work on a $500 (used) Model 140, though I've graduated to a faster and larger-screened Performa® Mac for most of it. But even the fastest new Mac and the latest in film printers cost less than $50,000 now, down over 90% in 13 years. And prices are going to nothing but continue to go down as faster processors, cheaper RAM and bigger storage devices appear.

There are few businesses that couldn't be helped with a newsletter and an easy way to generate promotions, so we'll be seeing more and more in-house publishing. There's a great opportunity there for people to become experts in this technology and consult for small businesses.

Outraged

I am outraged over the outrageous things people are getting outraged about. I'm up to here with political correctness and with the seemingly endless euphemisms invented to spare people's increasingly delicate sensibilities. Mental institutions, correctional facilities, Department of Defense, physically challenged, senior citizen, chairperson ... phooey.

More Bum Dope

A reader from Ohio claims the HamVention speaker chairman told him he didn't ask me to speak this year because I demanded a speaking fee, plus travel and hotel costs. I don't charge a speaking fee for hamfests. I do usually ask that my travel and hotel expenses be covered, though I did not ask this of the HamVention.

Here's exactly what I wrote to Ken Allen KB8KE: "While I was disappointed to again not be invited to be on the program, I can understand the pressures you must be under from the League... I'm their worst nightmare and you certainly can't afford to offend them. I've heard from several sources how they're gloating over being able to keep me off the program.

"My message this year is the most important I've had since I first spoke at Dayton in 1955, where I addressed the banquet. I'm calling for every ham club in the country to do their utmost to get at least one local ham elected to their state legislature. The next step is for this person to get on the educational committee and introduce a bill getting the state's schools to initiate an eight-year course in the fundamentals of electronics, communications and computers for grades 5-12.

"Our country desperately needs high-tech career workers to design, manufacture, sell, operate, and service the high-tech products which will dominate both business and home in the 21st century. This can help us get radio clubs started in every school in the country and revive the high growth we had from 1946 to 1964 (11% per year, steadily for 18 years!). Without something dramatic like this, how many years can we really hope to keep our hobby going, considering the mounting commercial pressures for spectrum and the billions they are willing to pay for it? Ham legislators have an added benefit to us of being able to provide some clout when matters of interference and antenna restrictions come up. We need to infiltrate the state legislatures, so I'm really disappointed that I won't be able to get this message across at the HamVention this year."

No, I didn't get any answer.

Most conferences pay the travel and hotel expenses for the speakers. I spoke at the Tesla Society in Colorado Springs, the Global Sciences Congress in Tampa, and the Edmonton Ham Convention last year on that basis. But it's tough for me to take the time to give talks, so I haven't been pushing it.

Ideas

If you'd follow the instructions in my $5 booklet, *Making Money, A Beginner's Guide*, you wouldn't have to have me think up ideas for ways to get rich. I keep coming up with great ideas for new businesses on at least a weekly basis. There are endless products and services which would sell well, but which aren't on the market yet.

When I was a kid I got a pair of in-line skates, but having just two wheels, they weren't easy to use. By adding a couple more wheels an entrepreneur has racked up hundreds of millions. How come you didn't think of that? Well, there's a wide-open opportunity for someone now to use modern materials and invent a pair of roller skates (the old kind) that are light and can be simply snapped on a pair of (probably special) shoes. What a great answer to getting around our cities! Beats the heck out of walking. But they have to be simple to put on and take off, and easy to carry around. The market? Millions upon millions of pairs for use in every city in the world. Yes, I've written about this before, but you haven't done anything about it yet. I don't want to hear any complaints about your not having money.

How about an idea for a new and badly needed publication? I sure wish I had the time to do this. This has to do with helping food companies introduce new products. Hundreds of new products are being put into our supermarkets every year, and zillions of dollars are being spent to build their sales. How about a magazine to sell at checkout counters which would provide information about these new products? I'd encourage the public to try the new products and then report on how they liked them. A vox pop approach. None of us put much credibility on product endorsements in ads, but where an independent magazine publishes customer reactions, this would be much more believable. And this is something no company could generate through advertising.

Yes, there would be both good and bad reviews. This is what I did when I published *CD Review*. It's the only way to maintain credibility. Sure, the major labels really hated it when we trashed one of their new releases, but since our readers were spending about $25-30 million a *month* on CDs, they had no choice but to advertise in my magazine.

It's different when it comes to high-ticket products like audio equipment. There my policy was to only publish favorable reviews. But we never did a favor-

able review on anything that didn't deserve it. This is my policy with *73* too. If a product is good, I want to help the manufacturer to sell it. If it isn't very good, we just keep quiet.

With the food business there are so many new products and their cost is low, so the reviews should be brutal where brutality is called for. In the long run that's helpful for the manufacturers too. It shortens the agony for crappy products and the company will lose much less in the long run.

Would supermarkets make room for a new magazine? Anything that helps them bring in more customers and sell more products will get good placement.

Yes, I seem to often think in terms of publications. Well, they're easy to start small and build. With today's desktop computers anyone with $1,000 can get into publishing.

How about a magazine or even a flyer called *Killer Bs*? This would review the B movies on tape, and there are thousands of 'em. Some are darned good, but how can you find out about 'em? You sure can't tell from the package. I might even rent some videos if I had a way to tell what was good.

For that matter, we need a lot better system for reviewing first-run movies. Oh, I tape "Sneak Previews" and Siskel and Ebert to see what they think, but I haven't found them very reliable. My idea is to go to the first showing of a new picture and poll the emerging audience. How did they like it? You could hire a dozen high school students to poll a couple audiences and you'd have information that would support at least a newsletter. I'll bet you could get a radio or TV spot on the news with your results too.

Next thing you'll be reviewing plays, new museum exhibits, and so on, the same way.

One idea I wrote about several years ago and you ignored had to do with organizing a CD for graduating high school and college classes. You'd get together with a local recording studio and make recordings of the bands, choral groups, etc., as a graduation keepsake. It would be like the photos of the graduating class.

There are a lot of schools within driving distance, so you could work up quite a business.

Just keep your eyes open and your imagination on the front burner and you'll be able to think of all sorts of part-time money-making opportunities.

If you have a computer and laser printer you can start doing newsletters for local businesses. They don't have the personnel, the time, or the equipment to do them, but a newsletter is a powerful selling tool. And by the time you're doing a dozen of 'em, you'll be very busy. The next thing you know, you'll be keeping their mailing list for them too.

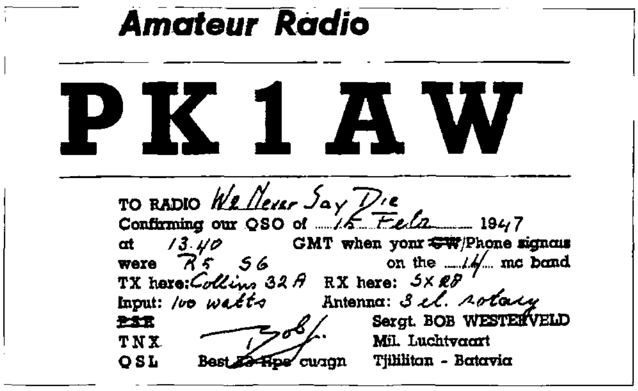
That ought to hold you for a while. If you'd like to read about more of my brainstorms, let me know. There's no shortage.

More Ideas

Money-making ideas, of course. There are all sorts of products and services out there just crying for entrepreneurs to step up and take a swing. Some will provide a fun and profitable life for you. Others will give you the opportunity to make millions—which is okay, as long as you don't get caught up in the pursuit of money as a goal in itself.

One wide-open opportunity is in the organization of hi-fi shows. Back in the 1950s, when I started my first manufacturing business, making loudspeaker enclosures, my main sales tool was demonstrating my product at hi-fi shows around the country: New York, Boston, Washington, Chicago, Los Angeles. These shows were in hotels and were packed solid with people listening and buying. Without those shows my speakers never would have become the best selling speakers in the country within two and a half years of their introduction. But I don't know of anything like that happening around the country now, and I'm too busy to do it, though I know the ropes, having put on a whopping computer show in Boston.

What happened to the shows? The industry, under pressure from Avery Fisher, took control and that was the end of it. Industry groups tend to be slow to meet changes. Look what happened to the IEEE and the NCC shows, once the largest in the country in electronics and computers. Pffft. Showmen can run successful shows, not committees.



Cold Fusion Gets Easier

When Doctors Pons and Fleischmann, two respected chemists, stuck a palladium wire into a lithium and heavy water solution, and then passed a current through it for some days—suddenly the cell started generating far more heat than any chemical reaction could explain.

Other scientists tried to replicate the experiment using palladium wire, sheets, and chunks. Many failed, but some succeeded. Those who failed went to the press to exposé P&F's fiasco. Those who succeeded kept working to refine to process—to make it work faster, more dependably, and generate more heat.

Physicists were adamant that this was not fusion because so little radioactivity was detected. Impossible. So, lacking any theory for why this "anomalous heat" was being generated, researchers went by the seat of their pants (empirical, it's called), trying this and that. Some were even getting heat using nickel and plain water.

The effect was best with metals having a lattice-like molecular construction such as palladium, nickel, rubidium, rhodium, and platinum. These metals acted like sponges, absorbing hydrogen. They found that around the time the lattices were 85% full of hydrogen the anomalous heat started appearing.

Jim Patterson, an inventor, and not a chemist or physicist, figured that since the start of the reaction depended on the metal absorbing hydrogen as quickly as possible, the more surface area of the metal, the faster it would absorb the hydrogen. So he coated some microspheres of polymer with palladium. Sure enough, the reaction started reliably in record time—in a few minutes instead of days. And the amount of heat increased amazingly. By last December he demonstrated a cell at a power company conference which was generating over a thousand watts of heat with only about one watt of drive. A thousand to one!

Hmm, said I, if those microspheres work so well, why not eliminate the spheres and just use cheaper and easier-to-make finely powdered metal. That would have even more surface area. Or go the next step to a chelated metal? Heck, go to even smaller metal particles by making a colloidal suspension of the metal in the electrolyte solution? Talk about surface area!

When I asked Patterson about this, he smiled and said he'd done just that and had some patents in the works. Jim's the chap who got the first cold fusion patent on his cell, and then the first patent claiming more energy out than in. Since that smacks of perpetual motion, which the patent office has always refused to even consider, this may be a historic first. It's real enough so Motorola and Bectel are already said to be licensed to help develop the technology.

Lest yon think that colloidal metals are something mysterious and difficult to brew, they're something you can make on the kitchen table yourself. In minutes. No, this cold fusion research field doesn't take a million dollar laboratory to get in on the fun. Indeed, the leading American researcher in the field (before Jim) was Dennis Cravens, a young teacher at a small college in Vernon, Texas. Dennis set up a small lab in his garage and, investing less than $5,000 in his equipment, was a true pioneer. I first met Dennis when he was delivering a lecture on his

New repeater in orbit

A new UHF repeater is in orbit using the callsign RRØDL. It's part of the Space AmateurFunk EXperiment (SAFEX) from Germany, and is fully operational from the *Mir* space station. You can work stations across North America via this 70 cm in-band FM repeater in space. Although it helps to use a home station with directional antennas and reasonable power, many stations have had successful contacts through the repeater using only handie-talkies and "rubber-duck" antennas.

What is SAFEX?

On October 30, 1985, the space shuttle *Challenger* was launched carrying the first German Spacelab mission. During the week-long mission a special crossband transceiver from Bosch was used by Dr. Reinhard Furrer DD6CF, Dr. Ernst Messerschmid DG2KM, and Dr. Wubbo Ockeis PE1LFO for ham radio contacts. The uplink was on channels between 437.125 and 437.375 MHz with a downlink on 145.575 MHz. Several hundred calls were heard by the German Spacelab hams and dozens of successful contacts were made. This was the first German amateur radio operation from space. Since then there have been several.

In 1992, the German ham activities went to *Mir* using the callsign DP1MIR. The second German Spacelab mission followed in 1993, once again with the callsign DPØSL. In the next two years the Russian-ESA (European Space Agency) operations continued with the DP3MIR endeavor in 1994 and the DPØMIR project in 1995.

In 1993, discussions and negotiations ensued between NPO Energia and Russian radio amateurs concerning future ham radio gear and operations onboard *Mir*. A new ham radio station for *Mir* was proposed. In 1994 three groups in Germany agreed to fund, design and build a new system to be mounted in the "Priroda" module in *Mir*. The German groups included the *Deutscher Amateur Radio Club (DARC)*, the Ham Radio Group at the German Aerospace Research Establishment (*DLR*) and the *Deutsche Agentur fuer Raumfahrtangelegenheiten (DARA)*. The Russians supported the installation in the "Priroda" module and the operation of the station.

Experience with earlier German and Russian space missions showed that astronauts and cosmonauts are very busy. The SAFEX-II system was developed to allow ham radio activity without constant intervention by orbiting hams. The popularity of the digital packet radio digipeater system used by the Shuttle Amateur Radio EXperiment provided a good model, but did not provide any unattended voice activity that a "flying" repeater can provide.

Mode 1: NBFM UHF Repeater
Downlink: 437.950 MHz
Uplink: 435.750 MHz
CTCSS Tone required for access.
Mode 2: 9600-Baud Packet
Downlink: 437.975 MHz
Uplink: 435.775 MHz
No CTCSS tone required.
Primary operation: digipeater.
Mailbox active with onboard laptop.
Mode 3: QSO Operation with *Mir* Crew
Downlink: 437.925 MHz
Uplink: 435.725 MHz
CTCSS tone required for access.
Digital voice recorder can provide beacon messages.
Packet transmission of digital pictures.
SHF Experiment: 10-MHz-wide linear transponder
Downlink center: 2410 MHz
Uplink center: 1265 MHz
Uses include high-speed data, ATV (FM or AM), etc.

Table 1. SAFEX-II frequencies for RRØDL on Mir.

The gear

The SAFEX system is comprised of two main units with various auxiliary components. The equipment weighs in at around 30 kilograms. Three external antennas are needed, along with significant electrical power. During normal operation, the complete system draws about 50 watts in a 24-hour period from the 28-volt *Mir* power bus, but can draw as much as 300 watts in two hours during high-power transmissions. The SAFEX gear can be commanded for frequency and mode changes by the cosmonauts, or remotely operated by ground stations in Russia (R3K in Moscow) and Germany (DFØVR in Oberpfaffenhofen).

A digital voice recorder and digital voice identifier system are included, along with a 9600-baud TNC (Terminal Node Controller) for packet operation. Appropriate filters are incorporated for the repeater and crossband modes. A 2 meter transceiver is not part of the current system, but will be installed for later crossband work.

The primary radio unit is the 430 MHz repeater with a 2.2 MHz offset between input and output frequencies. It can also be used for two-way contacts with those on *Mir*, or as an AX.25 packet digipeater, still with the 2.2 MHz split between uplink and downlink frequencies. A laptop PC can be connected to the SAFEX 70 cm unit for mailbox operation when in the packet mode. The packet system will also be used to send pictures from *Mir* using a special file format compatible with a new software version of JVFAX, currently in development. A digital camera is used to get an image that is subsequently stored in the laptop, and then transferred to the TNC.

During the first days of the SAFEX-II operation, the digital recorder was used to send a voice message on an FM downlink of 437.925 MHz. Early repeater operation required the use of CTCSS (Continuous-Tone, Controlled-Squelch System—also known as "PL" or Private Line) tones to activate the repeater on the uplink frequency. The tone used in July was 141.3 Hz, also known as EIA (Electronic Industries Association) code 4A. While this tone setting can be changed, it may become the standard for future operation. Refer to **Table 1** for uplink and downlink frequency details.

The second radio unit includes a crossband linear transponder with a 1265 MHz input and a 2410 MHz output. While use of the 70 cm system is geared more toward "normal" ham operation, the L/S-band system is an experiment designed to test techniques that may become more prevalent on future manned missions. The microwave transponder is 10 MHz wide and uses an IF (Intermediate Frequency) in the 70 cm band. This bandwidth is capable of passing high-speed data or even television signals. The ATV (Amateur TeleVison) group at the University of Bremen was tasked with the design and construction of many of the L/S-band components. The wide bandwidth of the transponder is sufficient to pass most AM or FM ham TV signals. For narrowband signals, however, the Doppler shift will be a problem. At 2410 MHz, a signal can exhibit over 100 kHz of apparent drift from AOS (Acquisition of Signal) to LOS (Loss of Signal) during an overhead pass. SSB (Single Sideband) or CW (Continuous Wave) operation will be a REAL challenge.

"Many stations have had successful contacts through the FM repeater in space using only handie-talkies and 'rubber-duck' antennas."

Finding *Mir*

The best way to track the *Mir* space station is to use a tracking program on a computer. Software can usually be purchased or found on various BBSs, via the Internet. A good source of quality programs is through AMSAT, the Radio Amateur Satellite Corporation. You can call for information at (301) 589-6062. Access via the World Wide Web can be found at http://www.amsat.org. A simple

Timeline	Downlink	Offset	Uplink
Start of Pass	437.960	-2.22	435.740
	437.955	-2.21	435.745
Closest Point	437.950	-2.20	435.750
	437.945	-2.19	435.755
End of Pass	437.940	-2.18	435.760

Table. 2. Doppler-correcting Mir repeater frequencies (MHz) for ground use.

alternative is to set a dual-band (2 meter and 70 cm) radio or scanner to listen on 145.55 MHz and 437.95 MHz. The 2 meter simplex frequency has been active for many years, and the 70 cm frequency is the *Mir* SAFEX-II repeater output.

Working the SAFEX-II repeater

At 70 cm frequencies, Doppler shift is a serious consideration for NBFM (Narrow-Band FM) work. The apparent receive frequency at the beginning of a pass will be as much as 10 kHz higher than expected. At the end, it will be 10 kHz lower. To get into the repeater, compensation must also be applied to the uplink signal.

Using the published uplink and downlink frequencies, effective communications can only be achieved through the repeater when the *Mir* space station is at its closest point to the observer. At all other times during the pass, corrections must be made to hear the repeater output and to get into the receiver.

Doppler shift is a result of the relative velocity of a moving object with respect to an observer. For a horizon-grazing *Mir* pass it will be at a minimum. For an overhead pass it will be at a maximum. Most new tracking programs allow the inclusion of a specific frequency for Doppler calculations. Use 437.95 MHz if your program has this option. It will provide data on what to expect when the space station comes over.

While listening at a higher frequency at the beginning of a pass, it will be necessary to transmit lower than expected to get into the repeater. For example, if the repeater signal is heard best on 437.96 MHz (rather than the published 437.95 MHz), the appropriate uplink will be on 435.74 MHz (rather than on 435.75 MHz). This correction will change during the pass. Continuously modifying the repeater offset in the radio during a 10-minute pass can be difficult. If your UHF transceiver has memories that can be programmed with different repeater offsets or input/output frequencies, an easy alternative is possible.

"The SAFEX-II system was developed to allow ham radio activity without constant intervention by orbiting hams."

In a typical 70 cm HT or mobile rig, with tuning increments of 5 kHz, program five different memory locations with appropriate receive frequencies and repeater offsets. Don't forget to include the 141.3 Hz CTCSS (PL) tone. **Table 2** is a list of five receive frequencies and suitable transmit offsets that will take care of the Doppler corrections needed during any pass. Simply tune for the best audio quality, and the programmed offset will provide the proper uplink frequency to center your signal in the *Mir* repeater receiver.

The SAFEX-II system will provide much more than just a high-flying repeater. With the high-speed packet and ATV-capable microwave transponder many experiments and exciting activities are possible. The German and Russian groups will be exercising the different subsystems in the months to come, and unlike a typical hamsat, there's someone always nearby to hit the reset switch, pull the covers off, or just pack the gear up for shipment back home for any needed repair. 73

Calculating Antenna Bearings

If you're a DXer who uses a directional antenna, especially a yagi or quad beam (which are unidirectional), then it might be nice to know the direction in which to point the darned thing. The trick is to know the *great-circle bearing* between your location and the DX location. That bearing can be calculated with some simple spherical trigonometry using a hand-held calculator or a computer program. Before talking about the math, however, we need to establish a frame of reference that makes the system work.

Latitude and longitude

The need for navigation on the surface of the Earth caused the creation of a grid system to locate specific points on the surface of our globe. **Figs. 1** and 2 show how this system works. *Longitude* lines (**Fig. 1**) run from the North Pole to the South Pole. The reference point (longitude zero), called the *prime meridian*, runs through Greenwich, England. The longitude of the prime meridian is 0 degrees. Longitudes west of the prime meridian are given a plus sign (+), while longitudes east of the prime are given a minus (-) sign. If you continue the prime meridian through the poles to the other side of the Earth it has a longitude of 180 degrees. Thus, the longitude values run from -180

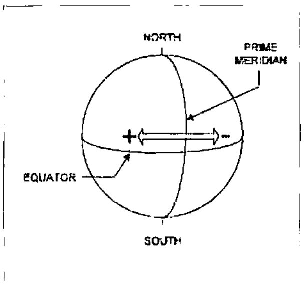

Fig. 1. Measuring longitude.

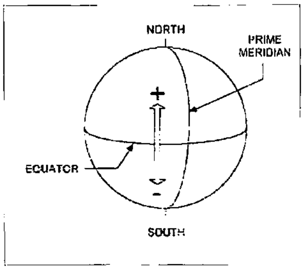

Fig. 2. Measuring latitude.

degrees to +180 degrees, with ±180 degrees being the same line.

The observatory at Greenwich is also the point against which relative time is measured. Every 15-degree change of longitude is equivalent to a one-hour difference from the Greenwich time. To the west, subtract one hour for each 15 degrees, and to the east, add one hour for each 15 degrees. Thus, the time on the east coast of the United States is -5 hours relative to Greenwich time. At one time, we called time along the prime meridian *Greenwich Mean Time* (GMT), also called *Zulu time* to simplify matters for CW operators.

"The great-circle bearing between your location and a DX location can be calculated with some simple spherical trigonometry, using a hand-held calculator or a computer program."

Latitude lines are measured against the equator (**Fig. 2**), with distances north of the equator being taken as positive, and distances south of the equator being negative. The equator is 0° latitude, while the North Pole is +90° latitude and the South Pole is -90° latitude.

Long ago, navigators learned that latitude can be measured by "shooting" the stars and consulting a special atlas to compare the angle of certain stars with tables that translate to latitude numbers. The longitude measurement, however, is a bit different. For centuries sailors could measure latitude, but had to guess at longitude, often with tragic results. In the early 18th century, the British government offered a large cash prize to anyone who could design a chronometer that could be taken to sea. By keeping the chronometer set accurately to Greenwich Mean Time, and comparing GMT against local time (i.e. at a time like high noon, when the position of the sun is easy to judge), the longitude could be calculated. If you'd like to learn more about this subject, most decent libraries have books on celestial navigation.

The great circle

The shortest distance between two points is a straight line, right? Nope, not on a globe. On the surface of a globe, a curved line called a *great-circle path* is the shortest distance between two points. This path can cause some interesting anomalies. For example, I live on a latitude that is close to the latitude of Lisbon, Portugal (in which case, why do *they* get the good weather?). Given that fact, one might assume that I would point my beam due east, at a bearing of 90° from true north. If I did that, I might hear Portuguese voices coming over the receiver, but they would be from the west coast of Africa, close to Angola (a former Portuguese colony).

Fig. 3 shows the basic problem of calculating antenna bearings. Consider two points on a globe: A is your QTH, while B is the other station's QTH. The distance D is the great-circle path between A and B.

The great-circle path length can be expressed in either degrees or distance (as miles, nautical miles or kilometers). To calculate the distance, it is necessary to find the difference in longitude (L) between your longitude (LA) and the other guy's longitude (LB): L = LA - LB. Keep the signs

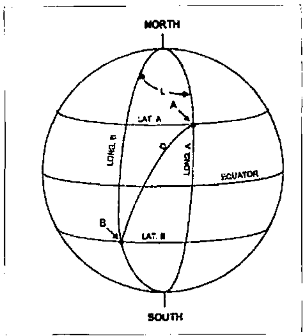

Fig. 3. The great-circle path.

straight. For example, if your longitude (LA) is 40°, and the other guy's longitude (LB) is -120°, then L = 40 - (-120) = 40 + 120 = 160. The equation for distance (D) is:

$$\cos D = (\sin A \times \sin B) + (\cos A \times \cos B \times \cos L)$$

D is the angular great-circle distance;
A is your latitude;
B is the other station's latitude.

To find the actual angle, take the arccos of Equation 1, i.e.:

$$D = \arccos(\cos D)$$

In the next equation you will want to use D in angular measure, but later on you'll want to convert D to miles. To do that neat trick, multiply D in degrees by 69.4. Or, if you prefer metric measures, then D times 111.2 yields kilometers. This is the approximate distance in statute miles between A and B.

To find the bearing from true north, then work the equation below:

$$C = \arccos\left[\frac{\sin B - (\sin A \times \cos D)}{(\cos A \times \sin D)}\right]$$

The problems

Now for the rub: This equation won't always give you the right answer unless you make some corrections.

The first problem is the "same longitude error," i.e. when both stations are on the same longitude line. In this case, L = LA - LB = 0. If LAT A > LAT B, then C = 180°, but if LAT A < LAT B, then C = 0°. If LAT A = LAT B, then what's the point of all these calculations?

The next problem is found when the condition -180° ≤ L ≤ +180° is not met, i.e. when the absolute value of L is greater than 180°, ABS(L) > 180°. In this case,

either add or subtract 360 in order to make the value between ±180°:

If L > +180, then L = L - 360
If L < -180, then L = L + 360

One problem seen while calculating these values on a computer is the fact that in BASIC the sin(X) and cos(X) cover different ranges (see **Fig. 4**). The sin(X) function returns values from 0° to 360°, while the cos(X) function returns values only over 0° to 180°. If L is positive, then the result of Equation 3, bearing C, is accurate, but if L is negative then the actual value of C = 360 - C. I ran across this problem when trying to compare the results of calculations from New York, NY (40.43N, 77W), to Japan and points in Australia. I had expected some bearings in the northwesterly direction because of the great-circle map published in older editions of the *ARRL Antenna Book.* Oops! After doing a bit more research, I found the error and added the test below to my program:

```
IF L < 0 then
L = 360 - L
Else L = L
End if
```

Another problem is seen whenever either station is in a high latitude near either pole (±90°), or where both locations are very close together, or where the two locations are antipodal (i.e. on opposite points on the Earth's surface). According to Hall (1973), the best way to handle these problems is to use a different version of Equation 3 that multiplies by the cosecant of D (i.e. csc(D)), rather than dividing by sine of D (i.e. sin(D)).

I have a Visual BASIC 4.00 program for calculating the bearing and distance, but the listing is not suitable for printing here. An executable version will be available soon, so contact me for price and availability if you want a Windows© program for calculating bearings.

Acknowledgment: My thanks to the ARRL Technical Department for aid in locating Hall's article, as well as other material on the problem of bearing calculations.

Never Say Die

Continued from page 51

work at the 3rd International Conference on Cold Fusion (ICCF-3) in Maui in 1993. Dennis is now working with Jim, helping him to develop his cells.

With most of the world pretty well discovered, today's pioneers are in the high-tech fields, bringing us cellular radio, packet, personal computers, and such.

Getting back to colloids. I ran into these first with my reading in the health area. It seems that colloidal silver is a miracle remedy for many problems. It's very easy to make. You merely put a couple pure silver wires in distilled water, add a little pure salt to make it conductive, and then pass a small current through it. In minutes you have a silver colloid solution. How much voltage does it take? 28 volts is fine (four 9V batteries).

I'm reading all I can on the use of silver colloids for health purposes and, when I get some time, I'll have a booklet available for anyone interested.

What's a colloid? It's particles of metal so small that they remain suspended in a solution and don't sift out when left undisturbed. We're talking very small particles, just a few molecules each. That's why there is such an enormous surface area for the cold fusion reaction.

Will it be Jim and Dennis demonstrating a cell generating 10,000 watts next year with one watt of drive, or you? How's your pioneering spirit? Have you ever had a desire to go where few have gone before? The threshold of the unknown isn't as far away as you think. I've been privileged to be good friends with several of our ham pioneers—Sam Harris W1FZJ who did pioneering moonbounce work and invented the parametric amplifier was a very good friend. As was John Williams W2BFD, the pioneer of radioteletype, Jack Babkes W2GDG with narrowband FM, and Wes Schum W9DYV with sideband.

The frontiers today are no farther away than they were a century ago. But instead of Africa, Tibet and reaching the poles, they're in digital voice, spread spectrum, cold fusion, and the

Ham to Ham

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

As *73's* "Ham to Ham" column begins its second year with this issue, I'd like to take just a moment to express my thanks for all of those contributors who've sent in their tips, suggestions, and ideas ... the meat and potatoes that keeps the column going and growing. I'm always looking for more, so don't hesitate to offer your own ideas to the list. There's a lot of information this time, so let's get right to it.

Lighten up

From George Vaughn WA4VWR: "I've found a local source for the bulbs that illuminate the Kenwood TS-940's subdisplay. When one of them went bad in my TS-940S, I removed both and measured the voltage applied to and the current drawn by the single working bulb ... 12 volts at 75 milliamperes. A trip to the local Radio Shack™ store resulted in my discovering standard RS replacement bulbs of the exact size and shape (RS Cat. #272-1092), but the RS bulbs draw 15 mA less, or 60 mA—and they lack the little green 'bootie' that the original Kenwood bulbs have. The 'bootie' can be carefully removed from the old bulb (provided it hasn't been cooked into place), and, with the aid of a touch of clear silicone grease, can be installed on the RS replacement bulb quite easily.

"The 15 milliamp difference in current (and light output) is about the same as if one were to put a 47 ohm, 1/2 watt 'bulb-life-extending resistor' in series with the Kenwood bulb, so to me it's perfectly acceptable. The biggest difference is in the price: $1.49 for two of the RS bulbs vs. $4.19 for each of the Kenwood replacements ($8.38 total) plus $6.00 shipping. That's $7.19 per bulb from Kenwood, 75 cents per bulb from Radio Shack. Guess which ones I'm using in the future.

"What about the TS-940S's 'S-meter' bulbs ... does Radio Shack carry a replacement for them? Yes, but this time the difference is more pronounced. The bulbs in the S-meter are 12V at 75 mA; the Radio Shack replacement with wire leads (Cat. #272-1141) is rated at 12V but this time at only 25 mA. It's noticeably dimmer than the stock Kenwood bulb, but it may be acceptable to many; you'd have to try it and see. Personally, I chose to use Radio Shack's Cat. #272-1143, a 12V, 75 mA bulb, but with a screw-in type of base. If you use the same bulb as I did, it's advisable that you not solder the 12 volt feed wire directly to the screw-type base, but rather wrap a couple of turns of non-stranded, fairly stiff wire around the screw-threads instead. Also, be sure to connect the 'ground' 12 volt feed wire to the screw-base, not the 'hot' wire. If the screw-base on this bulb were to ever cut through the insulating grommet, you might damage your set if the hot 12 volt lead were connected to it and then shorted the supply bus to ground. You can easily determine which feed wire is 'hot' and which is ground by measuring each with a voltmeter when the set is turned on. The 'hot' wire will have 12 volts on it and, of course, the ground wire won't. Again, make sure that the ground wire connects to the screw-base shell of the replacement bulb. The tip of the replacement bulb should be reasonably safe to solder the 'hot' 12 volt lead to, using the existing 'solder-blob' as a connection point ... do it quickly.

"One other small caveat: The #272-1143 bulb is just a tad too large to fit into the existing holes in the back of the TS-940S's meter, but a few seconds with a tapered reamer will result in the right hole size for a nice fit; take your time and don't get carried away! If done properly, the original Kenwood bulbs can still be used later on if desired. By the way, it is necessary to remove the metal meter mounting bracket to perform this particular step, but again, the cost savings are well worth the small extra effort."

Moderator's note: We've all noticed how difficult it's become to change the pilot lamps inside most of today's radios. In the old days, when both radios and lamps were a lot bigger, changing a pilot lamp was a pretty straightforward, easily accomplished job . The lamp was always mounted in a socket, and usually a twist of the wrist popped it right out. Not so today; most are now on small wires, soldered in place and buried deep within the wiring of the front panel. It usually requires some internal "surgery," so many hams either don't bother changing them at all when they burn out, or they leave the job for when the set has to be disassembled for some other troubleshooting reason. George has offered some well-thought-out advice in his tips from above; here's some more for you to consider.

More on lamps

What follows won't make the task of bulb changing any easier, but it just might double or triple the time between pilot lamp failures. When a lamp does burn out, many probably think first of going back to the manufacturer for a replacement. There's nothing wrong with that idea, especially if it's a very specialized type of bulb. But, as George pointed out, it's probably the most expensive and time consuming route to take, especially when there may be a much more cost effective approach. Since Radio Shacks stock a number of small, low voltage lamps, many of which will either fit directly or can be adapted to fit, a bit of "ham innovation" is sometimes needed, as exhibited in George's piece.

Take a look into what Radio Shack calls their 12V micro-lamp, Cat. #272-1092. It may well work as a replacement bulb for LCD displays and other situations where a very small size lamp is in order. Hobby stores also carry what they call "grain-of-wheat" lamps, which are very similar, but be sure to ask about their voltage and current ratings. By the way, using a lamp rated at a higher voltage is fine, as long as it will provide enough brightness once it's installed; in fact, it will last a lot longer than one rated at the nominal voltage. Additionally, if you lower the voltage to a 12V lamp, even by just a couple of volts, you'll increase its life dramatically. I've seen test curves that prove that the life expectancy of a lamp zooms upward as the voltage across it goes down, and vice versa of course. Putting a resistor in series with each lamp you replace will often give you two to three times the life expectancy from a given bulb, everything else being equal.

There are three things to consider before doing this: what value resistor will be needed; what its wattage rating should be; and how much loss of light is acceptable. Lowering the voltage to the lamp will decrease its brightness—and shift its color toward the red region—so you'll have to judge visually whether you can accept these consequences.

You can install the lamp, clip-leading a resistor in series with it, then looking at the meter or display under normal room lighting, to see if it's OK for your own particular situation. To arrive at the right resistor values, simply use Ohm's Law, plugging in the correct numbers for your own transceiver's lamp supply:

- Voltage drop desired divided by the lamp's rated current equals the resistance needed.
- Voltage drop desired times the lamp's rated current equals the resistor's wattage.

By way of an example, let's take the Radio Shack #272-1092 lamp that I mentioned before, which has a current rating of 60 mA or .06 amps. Let's say we'd like to drop the 12 volts feeding the lamp down to 10 volts, or a 2 volt total drop. We plug in the numbers:

2 (volts) divided by .06 (amp) equals 33 ohms;

2 (volts) times .06 (amp) equals .12 watt.

Now we know that we'll need a 33 ohm, 1/4 to 1/2 watt resistor in series with each lamp in order to drop the 12 volt lamp supply down to 10 volts. A 1/2 watt

resistor will provide a four-times-safety margin for heat dissipation (dissipation ratings for resistors generally assume their full lead length in free air, so it's safest to over-rate them by two to four times for shorter lead lengths and operation within confined enclosures).

By the way, try to avoid using bulbs intended for flashlight service; they're often high brightness, low life expectancy. There are charts available showing life expectancy at rated voltages for various lamp type numbers. The lamp's manufacturer can provide this information and it's also sometimes included in the more complete electronic supply house catalogs. It's surprising how much different lamps do vary in their average life expectations.

Don't "nit-pick" on Alinco!

Last month I gave you some tips on how to improve the Alinco DR-1200T's static discharge resistance with improved grounding. There are usually ways to improve upon just about any radio made. I'm not trying to nit-pick on Alinco, it's simply that I've become fairly familiar with this rig and feel comfortable attempting some "improvements."

This month I'll show you how you can make the internal CPU "reset" push-button accessible from the front panel. I'd be very interested in seeing submissions from readers on modifications that they've made to this and other popular radios; please just make sure that your tip is reproducible and that it doesn't create any "hidden" problems of its own. Obviously, I can't test all tips submitted to me for the column, since I don't have access to every rig on the market ... wish I did!

The Alinco DR-110T and DR-1200T/TH (and perhaps others in this line) have a hardware CPU reset push-button switch located just to the right (when viewed from the front) of the "Call/Call W" switch, but it can only be accessed from inside the radio, when the front plastic cover is removed. There's also a software reset (described in the owner's manual) that involves holding in both the "F" and "VFO/M" keys at the same time and turning the "POWER" switch on and off. But what if that doesn't correct your problem? The hardware reset switch actually momentarily grounds the reset pin on the CPU and should clear any conceivable programming error—at least anything that's curable by restarting the microprocessor.

It's an easy matter to add access to this hardware reset switch the next time you have the radio on your workbench. Simply drill a small hole (1/8" or so should do it) between the "Call/Call W" switch and the microphone connector. The hole should be carefully drilled from the inside to the outside (in fact, there exists a small "starter" hole inside the plastic front panel, as if they intended to make the switch accessible, then changed their minds). The finished hole is barely noticeable against the black background of the front panel itself, but it will give you access to the momentary hardware reset switch. Just use a thin, insulated probe to access the switch, should the CPU ever go bonkers and require a complete, non-maskable reset. Resetting the CPU will erase all memories and other user-defined data from the radio, but at least it will get you quickly back to "ground zero" again for reprogramming (you have a written copy of all of your programmed entries, right?).

Here's another quick tip for the same model of transceiver, in the spirit of the lamp tips mentioned earlier. If you don't want to go directly to Alinco for replacement display bulbs, I've successfully used Radio Shack's #272-1092, 12 volt, 60 mA "microlamps" as replacements. Chances are, they'll fit in other brands of transceivers as well for easily obtained replacement purposes, but always check for excessive heat buildup and too much current drain anytime you decide to substitute for a manufacturer's original part.

Short fuse

From John Ayers AA1IC: "It's often recommended by transceiver manufacturers (and others) that a mobile amateur transceiver's 13.8 VDC supply come directly from the vehicle's battery terminals, with a fuse or circuit breaker as close to the battery itself as possible (as opposed to simply picking up a feed from a convenient 'existing' battery voltage point somewhere under the dash). This practice will often cut down on the amount of noise introduced by the vehicle's electrical system into the ham rig, as well as minimizing RF interference from the ham gear getting back into the vehicle's computer or other RF sensitive electronics.

"Though the practice is strongly recommended, the hardware needed to accomplish it isn't always easy to obtain. For several years now I've been keeping my eyes open for the 'ideal' hardware to accomplish this job—something with adequate current capability and feed wire size, ease of physical mounting, and also suitably enclosed to prevent premature environmental-exposure failure. I've run across an automotive automatic circuit breaker at a local NAPA auto parts store that I feel meets these criteria. It's small, is rated at 20 amps DC, comes equipped with 10-32MS connecting studs, has husky mounting ears, and is fully enclosed against the elements (something we have to think about in our Vermont winters!). The one I chose is part #CB6317 and sells for under $6 including tax. If physical mounting within the engine compartment isn't practical in your installation, there is also an in-line model (without the mounting ears) that could be slipped inside a short length of PVC pipe (or other insulated covering) for added protection."

Moderator's note: If you're not able to find the circuit breaker that John mentioned locally, try obtaining a catalog from Parts Express, 340 E First Street, Dayton, OH 45402-1257 (513-222-0173 or 1-800-338-0531 for orders). They stock a variety of circuit breakers, fuse blocks, high-quality battery clamps, side mount posts, and other accessories needed for mobile audio and radio installations. They also carry the heavy primary wire (as large as No. 4 gauge), in any footage quantity desired, for extending your transceiver's cabling

right up to the battery itself. As John pointed out, you can often automatically avoid many mobile noise/interference headaches simply by using a "dedicated" radio 13.8V battery run ... or even a dedicated separate battery. A "clean" battery feed source (without random noises generated by other devices) is always the first step in any mobile installation noise elimination "foxhunt."

(Ed. note: Remember that the breaker must be mounted as close to the battery as possible for maximum protection.)

Net topics

From William Thim N1QVQ: "On some of our area repeaters, we have both general check-in nets and newcomer nets these days. But a group of us, N1TDW, N1SPJ, KD1ZV, and myself, came up with the following idea a while back. Why not have a local 'expert' net night when possible? We discussed it with the repeater owner, and he went for it enthusiastically and without hesitation.

"Basically, we encourage hams in the area with expertise on some particular aspect of ham radio to give an informal 20- to 30-minute talk on a subject in which he or she is experienced, followed by an appropriately timed question and answer session. Examples of subjects might be packet, satellite communications, the ins and outs of amateur TV, antenna construction and installation, weather nets, HF data modes, etc. The list is nearly endless since ham radio has so many interesting facets. The topics don't even have to be purely amateur radio: someone in broadcasting or emergency rescue could also keep a group riveted with a description of their profession and some of their interesting or off-beat experiences on the job.

"Start by suggesting one 'expert night' per month, then have the other area nets announce it on their own net night, repeaters and PBBSs and see if it doesn't increase your list of check-ins and 'future-ham SWL' listeners alike."

Power astray

From Jack VanGilder N3MPS: "My VHF packet station consists of a Kantronics KPC-3 TNC, in conjunction with a Kenwood TM-241A 2 meter FM transceiver. Both are powered by a 13.8 VDC external supply ... not an uncommon current-day setup. One day, however, my TM-241 wouldn't release from the transmit mode, was emitting a low-pitch tone, and the KPC-3 TNC became very hot to the touch.

"I immediately shut everything down and began to investigate. I discovered that the small coaxial power plug that supplies the 13.8 VDC to my KPC-3 had worked its way loose, pulling out just far enough to allow the 'normally closed' contact on the sleeve of the power jack to 'make' before the tip of the plug had broken its contact. I had installed the alkaline back-up batteries in the KPC-3, so the full 13.8 volts was placed across them by this unfortunate set of circumstances. The batteries apparently built up substantial internal heat and pressure, rupturing their seals and allowing their corrosive electrolyte to leak out into the TNC itself.

"What to do? I first applied some baking soda and warm water to the area affected, allowed it to neutralize any acids present, then cleaned the circuit board as best I could with a sponge and more fresh warm water. After permitting it to dry thoroughly, I was elated to find that everything was now working again. However, not wanting a repeat performance, I then made sure that the tip of the external power plug would disengage before the sleeve's normally closed contact had the chance to switch back as the power plug was slowly removed. It's probably also a good idea to remove the batteries whenever the unit is operated from an external power supply, as well as to insulate the battery terminal connector so that it can't come into contact with anything that it shouldn't inside the TNC.

"The lesson learned? Beware of those little coaxial power connectors (and others) that permit 'automatic' power transfer switching. Make sure that they 'break' before the other connection 'makes.'"

Moderator's note: Jack brings up a good point, and one that has the potential of creating problems in many other pieces of equipment. Any power connector that allows the "normally closed" contact to close before the external tip connection is completely broken is a candidate for the type of problem that Jack describes. This could be any item, from your daughter's portable stereo to your own telephone answering machine. Better put it on your list of things to check out; I know I have. Depending upon the actual circuitry of the device, you might be able to install a diode in series with the internal battery feed, with the diode's anode toward the positive battery output. This would permit current to flow only from (not to) the battery pack (you'll lose about 0.6 volts across a silicon diode, but that may not be consequential—you'll just have to give it a try and see).

Simply floored!

From Bob Boehm N8EXF: "Operating mobile, whether HF, VHF, or UHF, can be very challenging today with the smaller automobile interiors and plastic dashboards!

"I ran into a problem of where to mount my Kenwood TS-440S/AT in my Dodge 4x4 ... either the gear shift was in the way, or I couldn't reach the radio's controls! I solved the installation problem by building my own custom floor-mounted bracket out of Stanley™ brand preformed channel pieces from my local home improvement center. They come in various lengths and in 90-degree angles, allowing you to fabricate just about any kind of custom-fitted mobile floor mount that you might need.

"In the case of my own TS-440S, I used one 18" channel, cut it in half, and bolted a 90-degree 'T' section to each half. This formed the 'base' that was then bolted to the floor. Next, with two pieces, each 10" long, the vertical uprights were formed, onto which the mobile mounting bracket for my TS-440S was attached. The completed installation resembles an upside down 'T' when viewed from the side (see **Fig. 1**).

"It's withstood life in a 4x4 very nicely and the controls of the radio are within easy reach of the driver, without cramping anyone in the passenger's seat—the perfect solution in my own case. Perhaps this same idea can

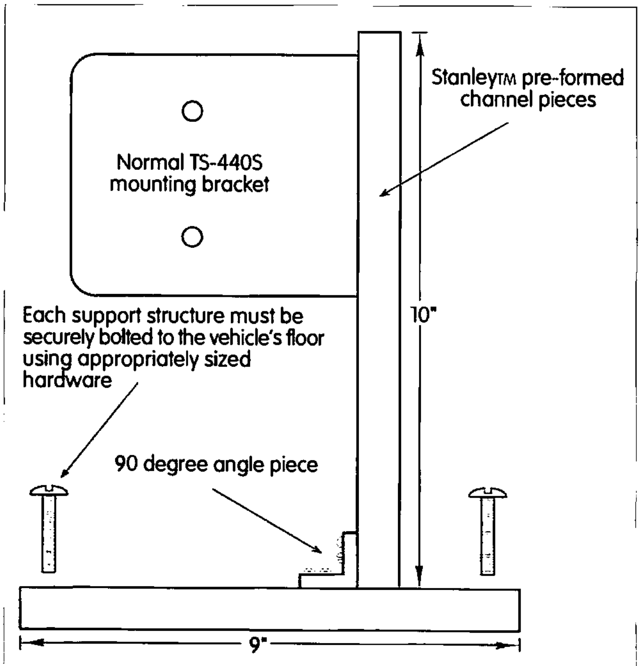

Fig. 1. Side view of N8EXF's idea for a home-brew floor mount to better position his Kenwood TS-440S HF transceiver in his Dodge 4x4. Two identical sections are needed, spaced to accommodate the standard Kenwood mounting bracket for this radio.

be adapted to solve your mobile installation woes as well."

Cable tie rip-off

In order to keep long lengths of coax cable, audio cable, power cable, etc. from tangling up when coiled, many hams use electrical tape around the cable coils when storing or transporting them. Tape works, of course, but it usually ends up leaving an unwanted gooey residue on the cable as well. Tape has a limited number of uses before it no longer adheres to itself, and, naturally, it's often lost when the cable itself is uncoiled for use. Fortunately, there is a much better solution, thanks to modern "fastener science."

The half-inch-wide sew-on Velcro™ material—not the self-adhesive variety—makes an excellent, permanently re-usable cable tie if the simple dimensions shown in **Fig. 2** are followed. Various lengths of Velcro are usually available in craft or fabric stores; just ask your XYL for her suggestions. As everyone knows, Velcro has two parts, a "fuzzy" soft-surfaced loop strip, and a "pinchy" harder-surfaced hook-strip. I'll just call them "fuzzy" and "pinchy" for easier identification purposes.

To make a single cable tie, cut about 6" of "fuzzy" Velcro and about 1" of its "pinchy" counterpart, place a few drops of household "super" glue (of the type containing cyanoacrylate ester) on the backside of the smaller "pinchy" piece, then place the two pieces back-to-back and squeeze them together securely between a couple of pieces of scrap aluminum, using a long-nose pliers, hemostats, or a vise, letting the glue cure.

Next, punch one or two small holes (a leather belt punch works nicely for this) into the free end of the "fuzzy" strip, large enough to pass a small, thin plastic cable tie-wrap (I use the 1/8" wide by 4" long #T18R plastic tie-wraps). These are the type of plastic tie-wraps sold in most electronic stores for permanently tying bundles of cables together, but in this case, it will be used to permanently fasten your new "Velcro tie" to the cable you're working with ... roughly 6" back from the cable's connector is generally about right (doubled-over waxed cable lacing twine also works nicely in place of the plastic tie).

Once the Velcro tie is fastened to the cable at the right point, with the plastic tie-wrap or lacing twine, just coil the cable up as you normally would. Once it's completely coiled, wrap the new Velcro tie—"fuzzy" side up—around the coil and press down on the "pinchy" strip to lock. Pull on the "pinchy" strip to unlock the tie. You now have a permanent, re-usable, always-close-at-hand cable tie system. A small "starter line" painted across the very end of the "pinchy" strip will tell you at a glance where to rip it open.

Make up as many ties as you'll need for all of your cables (including those on your power tools) and you'll thank yourself each time you use them ... it's a great rainy day or cold weather indoor construction project. Different colors of the Velcro material can be used to make up different colored "Velcro ties" for easy identification of different cable lengths or connector types.

Feel free to vary the dimensions shown in **Fig. 2** to accommodate smaller or larger cable coils. The dimensions shown seem to work well for "average" coils, so it's best to start by using them (at least until you're more familiar with the idea), then you can "customize" to your heart's content. By the way, don't steal your XYL's Velcro supply; I know the consequences of *that* mistake!

To UTC or not to UTC?

From Ken Guge K9KPM: "Many hams prefer to keep their station logs in UTC time, as opposed to local area time. It often makes QSLing much easier, since the DX station will probably use UTC time in his or her log (the use of UTC time seems to be much more popular with hams in other countries than with those of us here in the U.S.).

"One of the problems in using UTC time is the change-of-date that occurs at UTC Midnight. Here in North America that happens several hours before our local date-change; we sometimes forget about that fact. If you're going to be consistent in your log-keeping, the UTC date change must also occur at the correct point in time, yet none of the UTC clocks I've seen take that factor into account.

"My Timex Indiglo™ watch, however, does. It has two time display options: one for local time and date, another for an optional time and date. If UTC time is programmed into the optional display, the date will also be correct (on that display) following UTC Midnight—so the correct time and date for UTC are always just a 'touch of a button' away. You might want to take a look at these watches (and perhaps others with the same option) the next time the kids ask what you'd like for your birthday. Dads who are hams are easy to buy for!"

Two different worlds

In today's two worlds of electronics, analog and digital signals

NEVER SAY DIE

Continued from page 55

investigation of other anomalies of science. They're in rediscovering lost or buried past developments in health and other fields, such as the work of Royal Rife, which should be reopened. Ditto Wilhelm Reich. There are some amazing things happening with magnets. Just reading some of the books on my list of books you're crazy if you don't read will open all sorts of pioneering opportunities to anyone with imagination and curiosity. Whole continents of science are still there to be discovered. Which will you be prouder of 10 and 20 years from now, having watched Murphy Brown or some ball games, or having helped pioneer a new technology? This stuff doesn't take formal education—indeed, that seems to be a drawback when it comes to original thinking. It doesn't take a lot of brains either. What it takes is the same thing success at anything takes: persistence. That's what sets life's winners apart from the rest of us.

Beware The NSA

A reader sent me a copy of a couple articles from *Health Freedom News* that got my attention. The first was a reprise of the work Dr. Robert Becker reported in his fascinating book, *Cross Currents*. I've reviewed that book in a past editorial, but I didn't get you to read it. I'd hoped to get at least a few readers fired up enough to start experimenting with ways to regrow missing body parts through the use of low voltages.

The second part had to do with a friend of the author who had built a chamber which shielded a person totally from all electromagnetic fields. He put in antennas to detect the very low levels of frequencies given off by living creatures, then built a wideband amplifier to amplify the body emissions and then feed them back at a high level to get positive feedback. He found that animals could tolerate the treatment for about 30 seconds. He found the results to be amazing. The animal's genes and cells which are programmed for aging and death seemed to be reset backwards.

He found that three treatments a week apart was able to rejuvenate old and maimed cats and dogs. The next-door neighbor's dog, for instance, had been hit

Continued on page 61

must coexist, often side-by-side, on the same circuit boards in our receivers, transceivers and data controllers, yet the two varieties of signals are often mutually incompatible. Steep-wave-fronted digital data signals are often the most troublesome culprits in this coexistence battle, impressing "digital noise" of various kinds onto the more "peace-loving" analog signals. It's a problem that electronic circuit designers are continually fighting (and overcoming for the most part). Here are some of the proven techniques that they use.

Obviously, keeping digital and analog circuit components as far apart physically as possible is the first step, though not always entirely practical in today's crowded circuit board environment. But where it is possible, it's best to follow that axiom. Keeping parallel-running circuit traces or harness wiring with digital pulses and analog signals away from each other is also important. "Noise induction" is often the cause of crossover between those two worlds. Shielded cabling can help, even for circuitry that doesn't normally call for shielded wires. Multi-layering of boards, with digital and analog signals one above the other, is another source of cross-induction problems; sometimes shielding in the form of aluminum sheet-stock between the two can help in this area. Just make sure that any shield-planes are grounded only to their respective ground buses. This implies that digital and analog grounds and ground planes should also be separated from each other on the PC board(s), and they should be as large as possible to provide the least amount of resistive voltage drop (since that's where problems can sometimes begin). The use of separate positive power supply traces for the digital and analog portions of the circuit is also almost a must; make sure that all digital chips are powered only from the digital power bus and all analog chips or transistors are fed only from the analog feed point. A common power supply for the digital and analog circuits is usually possible, but separate plus power and ground leads to each separate power bus on the board itself is considered to be good practice. Using separate output regulator chips from a common power supply can also offer some noise crossover protection. Working to avoid ground loops, where the resistive loss in the loop can act as a development point for crossover noise, should be taken into consideration. If it's possible to ground coax cables on one end only, many potential problematical ground loops can be forestalled before they develop. Lastly, but certainly not leastly, generous numbers of bypassing capacitors, on both the analog and particularly the digital, power buses can save countless hours of troubleshooting and head-scratching later on. Bypass caps are inexpensive; use them freely.

Hopefully some of these tips may prove useful to both amateur digital circuit builders and circuit troubleshooters alike, since they can usually apply to both ends of that scale. It's often a mistake to assume that every precaution has been carefully observed in every manufactured item of ham equipment ... there's often lots of room for improvement. Just ask any dyed-in-the-wool equipment modification aficionado!

In closing

One closing note: Many thanks to Tom Miller WA8YKN (314 S. 9th. St., Richmond IN 47374) for allowing me to "beta test" his new "micro-sized" Bioelectrifier, the original circuit of which was first described in *73*, May 1996 issue, beginning on page 10. Tom did a beautiful job of reducing the circuitry, board size and battery compliment to their smallest common denominators. His revised schematic diagram is shown in **Fig. 3**. Tom also informed me that FAR Circuits (18N640 Field Court, Dundee IL 60118) is offering his board (only the PC board), and that Tom himself is offering a kit of parts and completely wired and tested units (less the enclosure). Contact FAR Circuits for the basic circuit board and Tom for the semi-kits (at the addresses above) ... asking for a current price list. Also always include a self-addressed and stamped envelope (SASE) when corresponding with those who have been thoughtful enough to offer us these boards and kits ... their margins are often too low to allow them to pay for the postage to answer our questions! Also, remember that the Bioelectrifier is for experimental purposes only, for enhanced plant-growth studies, and that it has no governmental approval for any other experimental use (does water have governmental approval for human consumption? I'm not sure).

This ends another month of "Ham to Ham." As mentioned in the beginning, we're now into our second year of the column and hope to go on much, much longer. Many thanks to the folks at *73* for making "Ham to Ham" possible. A special thanks to my principal proofreader and general guru of the often impractical English language, Sue Miller KA9UCK, and to Joyce Sawtelle of the *73* staff for her helpful support.

I still need your continued input to keep the column interesting. Send your ham-related tips, ideas, suggestions, and shortcuts to the address at the top of this column and share your findings with the rest of the *73* readership. They don't have to be "earth-shattering" or "cutting-edge technology" brainstorms ... just ideas you've found to be practical and helpful to you in your everyday amateur radio experience. Hope to hear from you soon. 73, de Dave, NZ9E.

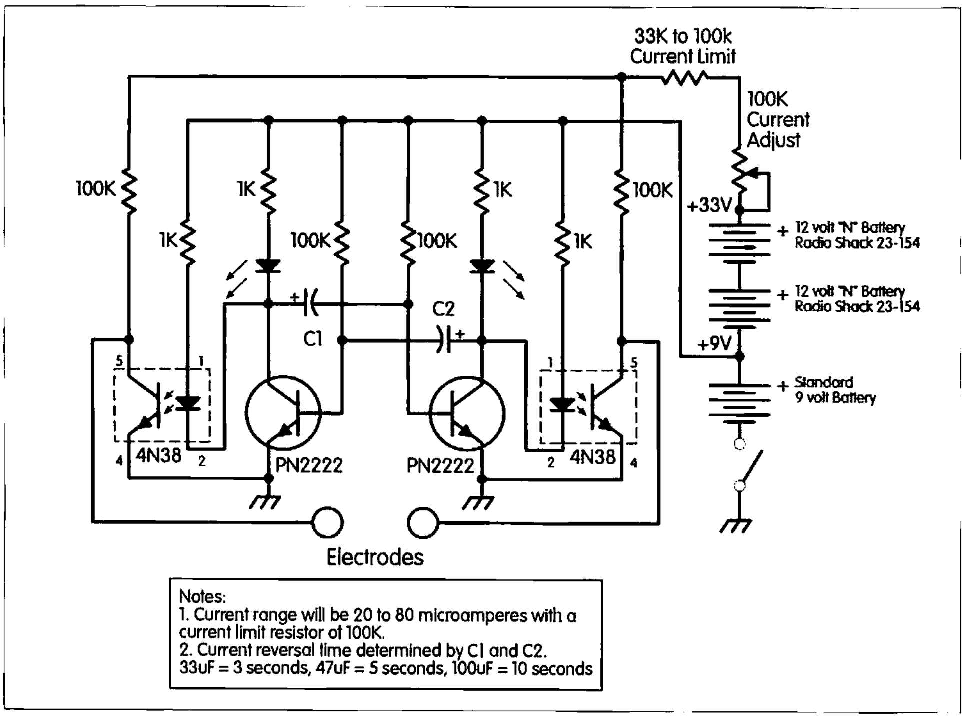

Fig. 3. *Tom Miller WA8YKN's revised and reduced Bioelectrifier, originally featured in the May '96 issue of* 73.

• Murphy's Corollary: "All matter will be damaged in direct proportion to its importance to the end-user."

NEVER SAY DIE

Continued from page 59

by a car some years before and a hind leg crushed so it had to be amputated. And there was spinal cord injury. The dog's hair was graying and falling out, it was overweight and had trouble breathing. Three months later the hind leg had regrown, the spinal damage healed, the dog's hair had grown back (now black) it had lost the excess weight, and was breathing normally. It was young again.

The physicist returned home a few days later to find the National Security Agency (NSA) cleaning out his papers and laboratory. They explained that he had no say in the matter. A few days later his house and lab were burned to the ground.

The NSA is twice the size of the CIA and operates both in and out of the US. It monitors phone and radio communications worldwide. All long distance phone calls and faxes are subject to monitoring by the NSA.

Now, if the above isn't total baloney, and I have no reason to suspect it is, maybe it's about time you started working on a shielded room and sending me articles on building wideband amplifiers. Considering the progress Becker made, the above isn't completely implausible.

I'm going to track down the author and see if I can get more details.

The article also mentioned a chap who has been working with magnetic fields. He immerses people in a strong field and body regeneration has occurred. One man had a tumor which blocked 90% of his spinal cord, making him a quadriplegic. 104 hours of treatment totally healed the tumor and the paralysis. Another, blind from degeneration of his optic nerve, regained full sight after six hours in the magnetic field.

I've got a good friend who is deeply involved with magnets and magnetism therapy. I'll see what he knows about all this.

Meanwhile, is any of that enough to get you to cut back on your TV and rag-chewing and do some experimenting? Sigh. I thought not. But if you do decide to experiment, keep quiet about it so you or your lab don't suddenly disappear. Well, not 100% quiet. I expect some confidential reports which I'll memorize and burn.

Insurance protection

Skip this section if you have no interest in your or your family's health.

Do HMOs or your company health insurance help keep you healthy? Sure, just as much as fire insurance keeps your building from burning and accident insurance keeps you from having accidents. Well, perhaps that's not an apt comparison since sometimes fire insurance tends to encourage "business fires."

How about doctors and hospitals? They mainly deal with relieving the symptoms caused by illness, and not with helping you avoid illness. No, that's up to you. And, as I've mentioned, your doctor is not one of the first people you want to turn to for advice. An AMA report showed that doctors live an average of 58 years, while the rest of us manage to live an average of 75 years.

Now, would you rather read my grumblings about the ARRL and the FCC, or pass along what I've been learning about how to live longer and healthier? At 74, and with one more average year to live, for some reason I'm paying more attention to maintaining and even maybe improving my body's health. I've got enough projects lined up so I'd like to counterbalance those doctors who died in their 40s by living into my 100s.

Well, I've already outlived "Bud" Budlong W1BUD, the League General Manager for many years. Knew him well. I knew Mort Kahn W2KR well too. He was the architect of the League's so-called "Incentive Licensing" proposal. As the Hudson Division Director he got together with some other directors and pulled a palace coup, where they threw Budlong out (he died soon after) and Kahn replaced him with a puppet, with Kahn pulling the strings from his yacht in Florida.

But you don't want to hear about all that dirty laundry when I could be explaining what I've discovered via one heck of a lot of research about recovering your robust health and preventing any of the normal illnesses such as cancer, heart trouble, arthritis, diabetes, and so on. I'm convinced that all that stuff is completely avoidable. Or, if you've already done the damage through ignorance, repairable.

Identity

There's a strong tendency among our revered "health care givers" to categorize us. Back in the days when I was a licensed professional mental repair technician, I quickly learned never to jump to any conclusions as to what was causing my patients' troubles based on seemingly similar cases I'd worked on with similar problems. The fact is that we're all different mentally as well as physically. And that difference goes right down to some basic levels.

This came to mind as I was reading a fascinating book, *The Pulse Test*, by Dr. Arthur Coca. The book was originally published 40 years ago, and is available in a pocket book 1996 edition. It's 186p, $5, and has ISBN 0-312-95699-1. Yes, it'll be in my next update of my list of books you're crazy if you don't read.

It points out that we're all allergic to different things—foods, dust, pollens, and so on. It also points out that we are probably unaware of our sensitivity to

Dayton '96 Youth Forum

There were lots of young adults in the audience at the Dayton Youth Forum this year; therefore, it was a success. The youngsters who interview to be presenters and who spend lots of time preparing their presentations enjoy a responsive, large audience of their peers.

The forum opened up with Maria Lopez, Clifford Uyeda, and the nice folks at Kenwood giving a little pep talk about youth in amateur radio. They also gave away several watches and Kenwood sports bags. It's my rule at the Youth Forum that prizes may be won only by people under the age of 18. This forum is for them!

The speakers

My first speaker was Beth Harris KJ7FC from Cheyenne, Wyoming. She is 15 years old, has an Extra Class license, and is last year's recipient of the ARRL's Hiram Percy Maxim Award. Beth's teacher exposed her to amateur radio in the seventh grade. She showed us a video that she and her teacher put together showing the elaborate satellite tracking station, moonbounce, and AMSAT equipment at the school's radio station. Beth spoke about how knowledge gained from being a ham has helped her in her various school studies.

Ken Fritz N3WAX is a 13-year-old Tech Plus from Glen Mills, Pennsylvania. Ken is active on RTTY and CW and enjoys operating special events stations like the Miss America Pageant and different Boy Scout events. He showed a series of slides from various club activities like Field Day, which he feels provides incentives for children to get involved and to upgrade their licenses. He stressed the importance of local clubs in helping to give newcomers a good start.

Sam Garrett AAØCR is 18 years old and is from Florissant, Missouri. He is the 1991 recipient of the Westlink Report Young Ham of the Year Award. Sam has spoken at several Youth Forums with me across the country in the past few years. He is a most accomplished young man. His speech was about how to use amateur radio to get scholarships for college. The scholarships are available to people of any age who want to pursue post-secondary education. Sam spoke about FAR, Foundation for Amateur Radio, which is a clearing house for administering scholarships for different groups. DARA, the Dayton Amateur Radio Association, has eight awards for $2,000 per year to aid college-bound students. The ARRL Foundation is a large resource for lots of scholarships. Through a single application process, you can gain access to many sources of funds. He also mentioned Chavarim of Philadelphia, which awards money to qualified hams of the Jewish faith. The Radio Club of America has permanent grants in place at several universities and technical colleges across the country. Interested applicants can contact FAR for more details.

Sam also made another good point: Add amateur radio activities to college résumés to show involvement in community activities.

My next guest from industry was Richard Stubbs KC5NSZ, who is the customer service manager for MFJ. Martin Jue, who is the founder of MFJ, deserves a tremendous amount of credit for always being so supportive of educational efforts in amateur radio. He has been good enough to send Richard to several of my youth forums and to make wonderful presentations of radio gear to winning children. The young man who won the MFJ 9420X 20 meter travel radio was in attendance at the Youth Forum in the hope of getting inspiration to become a ham. What better "inspiration" could there be?

Photo A. Carole Perry WB2MGP gets Dayton Youth Forum participants ready ahead of time.

***Photo B.** Left to right, front row: Sam Garrett AAØCR, Beth Harris KJ7FC, Sarah Wisutzkey, Kirk Severson KBØLNM, Ken Fritz N3WAX, Jeremy Graham N9OWS. Back row: Carole Perry WB2MGP, Ben Fenster KBØOVM, Mike Ballbach NØZTQ. Photo by Mrs. Ballbach.*

Jeremy Graham N9OWS, age 14, was next to speak. He talked about the close relationship between various Boy Scouting activities and amateur radio. Different merit badges, like Orienteering, utilize map and compass skills. He told about how valuable he was on a campout when he and some other Scouts were separated from the group. Having the radio with him helped make things a lot easier. Jeremy got a pleasant surprise after speaking—he was called back up to the podium 10 minutes later to receive the prize of an ICOM W31A 2m/440 dual-band radio, presented by Chris Lougee. Chris has given away ICOM rigs at almost every Youth Forum I've run. Let's all remember to support those manufacturers who are supportive of young people in the hobby.

"Sam AAØCR made a good point: Add amateur radio activities to college résumés to show involvement in community activities."

Cathy Lentz KBØFDU is 19 years old and has spoken at my forums before. From Hiawatha, Kansas, she has the distinction of being my first married youth forum speaker. The fact that she's also a busy young mom made her appearance that much more special. Cathy has a starring role in the amateur radio promotional video "Always On The Air" being produced by Bill Pasternak and others. She showed us the first few minutes of the tape. It looks like a winner. Cathy spends time going into local schools to do radio demos for the children. She suggests that many schools require community service of their students, and that teenaged hams might want to look into doing demonstrations as a way of earning this credit.

The last presentation was worth waiting for. Under the guidance of Ellie and Rip Van Winkle from the Boulder Amateur Radio Club in Colorado, the BARC Jr. "Dayton Team" did a round-table discussion, along with a wonderful talk about why their club is so successful with youngsters. The team consisted of chairman Mike Ballbach NØZTQ, 16, with an Advanced license; Ben Fenster KBØOVM, 13, with a Tech Plus license; and Kirk Severson KBØLNM, 13, with a Tech Plus license. Sarah Wisutzkey, a fourth-grader, was the alternate who attended all the meetings with the boys. The team gave the audience at Dayton some valuable information about fund-raising ideas like raffles, donations, loaner radios, and many more creative approaches needed to raise the money for the trip to Dayton for the team. For the last few years Ellie NØQCX has provided me with excellent young speakers for the Dayton Youth Forum. BARC Jr. is lucky to have such dedicated elmers and elmiras to help them out and to encourage them in their amateur radio activities.

The interest of young people going to the Internet is something for all of us to consider. That's one reason these youth forums are so important. We, as adults, the parents and the teachers, have to listen to what the youngsters are saying about what motivates them and what interests them.

Hope to see lots and lots more children at Dayton in '97! 73

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

This is a special 10th-year column. Yup, 10 years of "QRP." It's hard to believe that it's been that long since I started this column for *73*. A lot has happened to both ham radio and QRP in the last decade. Let's look back and then put our sights on the next 10 years.

Personal

When I started this column, there was the ever-popular "Hate Mike Bryce Club." The two primary members were my wife Lynnette and friend Terry. Well, the club folded in 1988. Lynnette left me for Terry and I joined the singles' ranks. And the Hate Mike Bryce Club folded. Two years later, I met a very attractive woman with a passion for the old and unusual. I fit right in so we were married on Field Day of June 1990. Donna and I spent our honeymoon chasing W6s on 40 meters.

While Donna had no interest in radio, and still does not, she delights in the hamfests. Always looking for old radios to repair, I became rather proficient at fixing old tube-type receivers. Between antique clocks, old radios and teddy bears, we have an interesting home! And personally, I wouldn't change a thing.

Clubs

In 1986 when I started this column, there were perhaps three QRP clubs of international fame. They were the QRP ARCI, The Michigan QRP club, and the G-QRP club. Today, all three are alive and well, and all three have shown outstanding growth in their ranks.

Perhaps more important has been the growth of smaller local-based clubs. There are now local clubs in nearly every corner of the union. Here is a short list of some of the clubs that have emerged: The New England QRP Club, NorCal, The NorthWest QRP Club, The St. Louis QRP Club, and The Colorado QRP Club. There's more to the list than I have included; if nothing else, this shows that activity in low power ham radio is growing.

Perhaps the most popular topic I've covered in this column has been building equipment. I've tried to cover the spectrum from easy-to-build to out-and-out stupid! There are several projects that still leave a warm spot in my soul. Here is a quick look at some of my personal favorites.

The Two-Fer

The Two-Fer was a simple VXO-based transmitter that was easy to build. You could assemble it in less than half an hour. With a whopping 1 watt output, the Two-Fer could easily work the world. While most of us assembled the Two-Fer transmitter, there was a matching direct conversion receiver that didn't work worth a hoot.

I don't know how many Two-Fer transmitters were built. I'd guess well over a thousand. To this day, I still get requests for parts kits and PC boards for this project.

As popular as the Two-Fer was (and is today!), there came several improved versions of the basic circuit. Of course, those new and improved Two-Fers were given plenty of space here in the column.

The 6L6 Special

I started this project as something to do on the weekends while Donna worked. It was also the birthday for the 6L6. I built a few tube-based transmitters when I got my Novice ticket way back when, so out came the Greenlee chassis punches and a trip to Perry's QTH. Perry W8AU has the world's largest walk-in junk box!

With its single 6L6 and a 5U4 in the power supply, the 6L6 Special would produce about 10 to 14 watts of RF—if you wanted to be mean. Operation was crystal-controlled on 80 and 40 meters. If you poked, beat and kicked the poor guy, you could manage 20 meters as well. Also, if you pumped the plate voltage up and bolted the little 6L6 down, you could zap out 50+ watts, for a short time.

The mail produced by the 6L6 Special was huge. I got letters from old-timers who'd renewed their interest in ham radio all because of the 6L6 Special. Oh, and then there were the letters from the new hams confused about the dipping and peaking of the 6L6!

> **"QRP does not mean using decades-old circuits; you'll find plenty of microprocessors in our QRP gear."**

I have no idea how many versions were built, but I'm sure the 6L6 Special generated a lot of warm fuzzies for many a ham.

The T/R Switch

One of the first projects to appear in the column, this was very popular with builders. The switch allowed painless interfacing between a QRP transmitter and receiver. It also generated a sidetone and provided a key interface.

On the downside, right after the T/R Switch was published, Radio Shack™ discontinued several key parts. That made the PC board outdated. As popular as the T/R Switch was, I'm planning an updated version. Look for it in the coming months.

The Pulse Charger

This guy started out on a whim. I never expected it to take off like it did. So popular was the Pulse Charger that I redid the original article and produced a PC board. I received requests for boards from all over the world—I even had a small company ask about building the Pulse Charger for commercial use.

There are probably a dozen more projects that were just as popular, but the ones described above seemed to generate the most mail.

Hate mail, farts and fizzles

The column titled "The Oscillator From Hell" generated more hate mail than you can imagine! I guess it was aptly named! To this day, I still get nasty letters about that column.

Ham Radio Fun

Number 64 on your Feedback card

Communications Simplified, Part 10

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Now that we understand the fundamentals of AM and FM, it is time to look at a typical radio receiver.

Fig. 1 shows the same crystal radio we introduced in Part 6 (*73*, June 1996). We pointed out that it consists of just a few parts:

1. An outside wire antenna, which captures all the various radio signals coming our way.

2. An antenna coil and variable capacitor, which do two jobs. The antenna coil is wired as a transformer, coupling the antenna signal to the radio. The secondary of the coil along with the variable capacitor also form a tuned circuit which selects the station we want, while rejecting stations we do not want.

3. A diode which rectifies the AM signal.

4. A 0.001 µF capacitor which filters out the high-frequency carrier and sidebands, and keeps only the envelope—the audio signal.

5. A pair of headphones which convert the audio signal to sound.

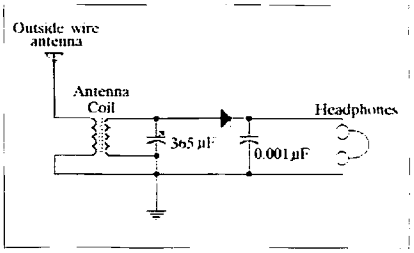

Fig. 1. A simple AM crystal radio.

Variations of this radio circuit date back to the early days of radio. The big advantage, of course, is that it is simple and requires no batteries, but that simplicity carries a price—the radio doesn't work very well. It has poor sensitivity and poor selectivity.

Sensitivity

The term *sensitivity* describes the ability of a radio to pick up weak signals. Our crystal radio has low sensitivity: it can pick up only really strong stations.

Sensitivity has to be judged in relation to noise. Just picking up a station is not enough if the station is so noisy that it is not pleasant to listen to. Spec sheets and advertising literature usually specify receiver sensitivity by measuring how much voltage from the antenna (usually measured in microvolts) is required to make the desired signal (usually the sound out of the speaker) 10 times or 100 times stronger than the noise. This ratio of signal to noise is then called the *signal-to-noise ratio*; a decent radio might provide a 10-to-1 or 100-to-1 signal-to-noise ratio with an antenna signal of under 1 microvolt.

This definition of sensitivity is useful for most radio receivers, but not for a crystal radio. Typical receivers have amplifiers which produce noise when tuned to a weak station, or to no station, so measuring the signal-to-noise ratio is possible. With a crystal set, however, there is really no noise to be heard from the headphones, so measuring the ratio is tough. Still, you need several hundred thousand microvolts of antenna signal to hear anything at all, so sensitivity is clearly bad. The signal-to-noise ratio (and many other quantities as well) is usually measured in decibels, so let us pursue this a bit more.

When we compare two voltages or two currents, the decibel formula is:

$$\text{dB} = 20 \log_{10} \frac{\text{(voltage or current after)}}{\text{(voltage or current before)}}$$

Let's look at a simple example to see how that applies to measuring sensitivity.

Suppose you turn on a receiver, disconnect the antenna (so there is no input signal), and adjust the volume control to get some measurable amount of noise from the speaker. Measure the speaker voltage and call that the "before" voltage. (For our example, suppose it is .7 volts.)

Now connect the receiver's antenna leads to a signal generator, properly adjust its frequency so the radio can receive it, and set the generator output until the receiver's speaker voltage is 7 volts (10 times more than before.) Call this the "after" voltage; it is the voltage needed to provide a signal 10 times stronger than the noise.

Now insert the "before" and "after" values into the formula for decibels:

$$\text{dB} = 20 \log \frac{\text{(after)}}{\text{(before)}} = 20 \log \frac{(7)}{(0.7)}$$
$$= 20 \log 10 = 20 \times 1$$

(since 10 to the 1st power is 10, log 10 is 1). And so the answer is 20 dB.

Now go back to measure the amount of signal coming from the generator into the receiver antenna connection. This value (in microvolts) is the sensitivity to produce a 20 dB signal-to-noise ratio in the receiver output.

Strictly speaking, this is not entirely correct, because the "after" measurement is not just the signal, but also

includes a bit of noise. Hence, many people will call our 20 dB value the *signal-plus-noise-to-noise* ratio, rather than just the signal-to-noise ratio. They may also write it as (S+N)/N, meaning that the signal-plus-noise is divided by the noise output.

Selectivity

Selectivity describes the ability of a receiver to select the station you want, and keep out other stations that you don't want. Our crystal radio has poor selectivity because it has trouble separating nearby stations.

As we've discussed in previous parts, a radio signal consists of a carrier and sidebands, and has a certain bandwidth which depends on the type and amount of modulation. Resonant circuits in the receiver tune in the station you want. Ideally, they should pass all the frequencies in the carrier and sidebands equally well, and completely reject all other frequencies below and above; in reality, however, that is not possible.

DETOUR

At this point, we need to review resonant circuits. **Fig. 2** shows a parallel-tuned resonant circuit of the type most often used in radio receivers. The basic tuned circuit consists of the inductor L and capacitor C, in parallel with each other. An AC input voltage is applied through the resistor R_{in}, and the output connects to a load resistance R_{load}.

If we were to disconnect the L and C, then the input signal would go straight to the output load. Of course, there would be a loss because of current in the two resistors (which make up a voltage divider), so that the output voltage would be smaller than the input voltage. Let's ignore this, though, and just consider the present voltage to be 100%, or the maximum of what it can be, considering the two resistors.

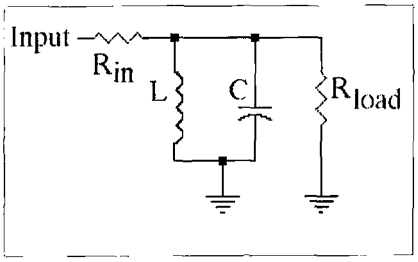

Fig. 2. A parallel-resonant circuit.

When we now connect L and C, there is some current through the inductor L, and also current through the capacitor C; as a result, the output voltage will generally drop. If the voltage drops to 50% of what it was before, we will say that the response of the circuit is 50% or, rather than use percents, we will simply call it 0.5; similarly, if the voltage drops to 80%, we will say that the response is 0.8.

So the response depends on the currents through L and C. There is an important frequency, called the *resonant* frequency, at which the currents through L and C are exactly equal, but opposite in direction—when one current goes up, the other goes down. In this case, the two currents exactly cancel each other out, and it is as if L and C were not there. In other words, at the resonant frequency we get the maximum 100% output voltage; we then say that the response is 1.

"If the superheterodyne receiver had never been invented, communications as we know it would probably not exist."

The resonant frequency is the one at which the reactance of C and the reactance of L are equal; that is,

$$X_C = X_L$$

$$\frac{1}{(2\pi f C))} = 2\pi f L$$

Solving this last equation for f gives us:

$$f = \frac{1}{(2\pi \sqrt{LC})}$$

This is the resonant frequency of this circuit. At this frequency, the output from the circuit is the highest (limited, of course, by the values of the resistors).

As soon as the frequency goes either above or below the resonant frequency, the two currents no longer cancel, and the output voltage drops. The left curve in **Fig. 3** shows the response of this circuit as the frequency changes. We see a peak at the resonant frequency, with a drop above and below that frequency.

Fig. 3 shows the actual frequency response of a tuned circuit at the left, and the ideal response we would like to have

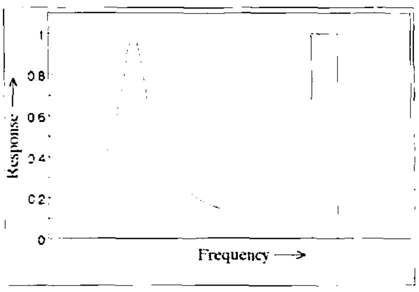

Fig. 3. Actual and ideal resonant response.

for a radio at the right. The ideal response would be a rectangle, where *all* the signals within the bandwidth of the radio signal (carrier and sidebands) get through equally well (the response is 1 or 100%), while *nothing* gets through above or below that range (the response is 0 or 0%).

You can see there is a big difference between what we want and what we get. The ideal rectangular response at the right has:

1. A flat top. This lets the carrier and all sidebands get through the tuned circuit equally well.

2. Steep skirts. The skirt is the vertical part at the left and right. Steep skirts make sure that the response drops very fast, so that no adjacent stations get through.

3. A definite bandwidth. Ideally, this should be just as wide as the bandwidth of the signal we are trying to receive—no more, and no less.

The actual tuned circuit response shown on the left in **Fig. 3** has none of these. The top isn't flat, so the carrier can get through, but the farther out a sideband is, the less of it gets through. The sides aren't steep enough to keep out adjacent stations, since even pretty far away from the peak the curve still has fairly high response. Finally, there is no definite bandwidth to the circuit.

We can flatten out the top a bit by widening the whole curve. The relative width of the curve is determined by a number called the *Quality Factor*, or *Q*, of the circuit.

The Q describes how wide or narrow the response curve is. For instance, **Fig. 4** shows several different response curves with different Q. The higher the Q, the narrower the response is; the lower the Q, the wider it is. You can see

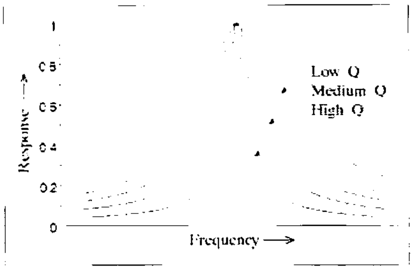

Fig. 4. How Q affects the shape of the response.

that a lower Q would even out the top—but it also widens the bandpass and makes the skirts even less steep.

Fig. 5 shows how the Q is measured. To find the Q, you need two measurements—the resonant frequency and the *3-dB bandwidth*, also often called the *half-power bandwidth*. The resonant frequency is simply the frequency at which the response is a maximum. In other words, it is the frequency of the peak.

The 3-dB or half-power bandwidth is a bit harder to measure. This bandwidth is defined as the difference between the two frequencies where the response drops by 3 dB from its peak value. This also happens to be the point where the output power drops to half of the power at the peak. This needs a bit of explanation.

Look at **Fig. 5**. At the peak, the response has a value of 1. Going down 3 dB from the peak gets us to a response of 0.707 (or $\sqrt{2}/2$, to be exact.) If we insert these values into the formula for voltage decibels, we get:

$$20 \log \frac{0.707}{1} = 20 \times (-0.15) = -3 \text{ dB}$$

In other words, when the response drops to 0.707 of its value at the peak, it has dropped 3 dB from the peak.

This point also happens to be the half-power point. Suppose the output voltage from the circuit is 10 volts at the resonant frequency, and it goes into, say, 100 ohms. Then the power output would be:

$$P = \frac{V^2}{R} = \frac{10^2}{100} = 1 \text{ watt}$$

At the 3-dB point, however, the output voltage drops to 0.707 of its value at the peak, or just 7.07 volts, so the power is now:

$$P = \frac{V^2}{R} = \frac{7.07^2}{100} = \frac{50}{100} = 0.5 \text{ watt}$$

We can use the equation for power decibels to check that 0.5 watt is 3 dB less than 1 watt:

$$10 \log \frac{0.5}{1} = 10 \times (-0.3) = -3 \text{ dB}$$

So back to **Fig. 5**. What we do is to go to the curve, find the two frequencies (one lower than the resonant frequency, and the other higher) where the output drops to 0.707 of its value at the peak, and find the difference between them. This is labeled BW in **Fig. 5**. The Quality factor Q is then defined as:

$$Q = \frac{\text{resonant frequency}}{\text{BW, the 3-dB bandwidth}}$$

The Q is affected by the resistances in the circuit. In **Fig. 2**, the input resistor and the load resistor both affect the Q—the lower the resistors are, the lower the Q. (The resistance of the coil also affects it a bit, but the two resistors have the greatest effect.)

END OF DETOUR

Now that we know some more about resonant circuits, compare **Fig. 1** with **Fig. 2**. The antenna and the primary of the coil in **Fig. 1** feed the signal into the tuned circuit, so their resistance affects the Q. The headphones are the load on the circuit, so their resistance also affects the Q, and, because all of these have fairly low resistance, the Q is terrible! In a typical crystal radio, the response of the tuned circuit is so wide, and the skirts so broad, that it is almost impossible to separate stations from each other. Unless you are lucky to live very close to one radio station and far from all others, don't expect to get very good performance from a crystal radio.

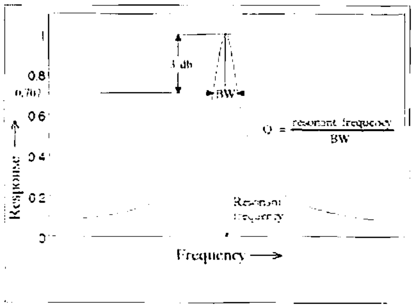

Fig. 5. How to measure the Q of a resonant circuit.

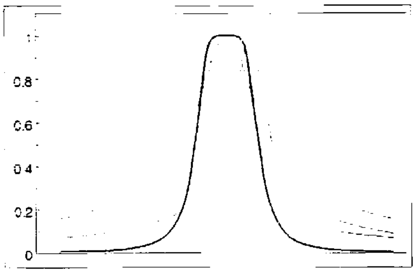

Fig. 6. Improving the bandpass by combining tuned circuits.

How do we improve sensitivity and selectivity?

Improving sensitivity seems fairly simple—just add some amplifiers. Well, it's not quite that simple, because you have to do it just right, as we shall see in a moment, but it *can* be done. Improving selectivity, on the other hand, is somewhat more complicated. There are some modern components, such as crystal or ceramic filters, which can provide a fairly sharp bandpass. The more traditional method, however, is to just add more tuned circuits. For example, the dark curve in **Fig. 6** shows how using three resonant circuits, each tuned to a slightly different frequency and having different Qs, can improve the overall response. There are several ways of getting this same result, and, obviously, the circuit must be carefully designed and set up, or else the resulting bandpass may be lopsided or have lumps in the top.

The problem is that you can't just parallel a bunch of tuned circuits together, as in **Fig. 7**. Even though this looks like three separate tuned circuits, if you parallel the three inductors into one, and the three capacitors into one, you see that there is really only one tuned circuit here. To use more than one tuned circuit in the radio you must somehow separate them so they are not all in parallel with each other. The secret is to separate them with amplifiers.

The TRF or tuned radio frequency receiver

The TRF, or tuned radio frequency receiver, became popular as soon as the

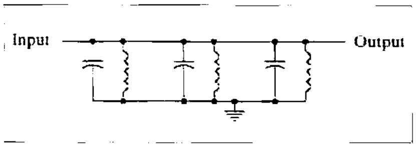

Fig. 7. This is one tuned circuit, not three.

electronics industry got to the point where it was possible to build amplifiers cheaply enough. **Fig. 8** shows the block diagram.

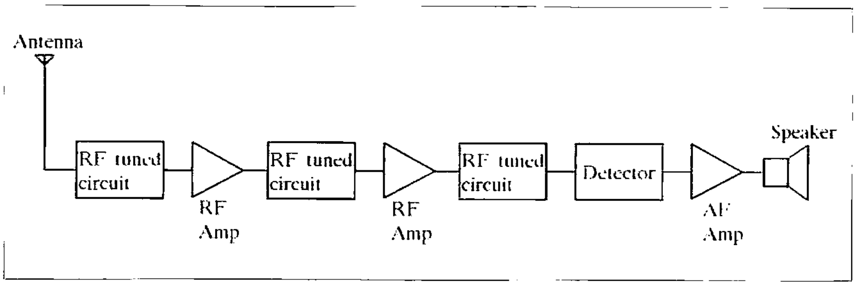

Fig. 8. The tuned radio frequency (TRF) receiver.

The circuit started with an antenna, usually a longwire strung outdoors. Then came two or more RF tuned circuits, separated by RF amplifiers. These were called RF because they all amplified the actual radio frequency (RF) signal. Eventually came a detector, which was simply a rectifier diode and capacitor, that worked just like those in the crystal radio shown in **Fig. 1**. This was followed by an AF amplifier, called AF because it now amplified the audio frequency signal, not the radio frequency signal. The audio signal then went to a speaker. You'll note how RF amplifiers separated the tuned circuits, so they would act separately instead of becoming one single tuned circuit, as in **Fig. 7**.

The TRF receiver worked quite well for its time, but it had some major problems. One difficulty was that each time you wanted to change stations you had to retune all the tuned circuits. Although **Fig. 8** shows only three, some more expensive radios had four or even more. But as **Fig. 6** shows, even three tuned circuits have to be carefully adjusted if you want to get an overall response with a fairly flat top and steep skirts. It was almost impossible for the average owner to get it right.

A second problem had to do with the actual physical construction of the radio. If two tuned circuits were too close to each other, the two inductors would act as a transformer. Some of the amplified signal from one of the later stages would get back into an earlier stage, only to be amplified again and again—this positive feedback made the radio into a perfect oscillator! The more tuned circuits there were, or the more gain the amplifiers had, the worse the problem became. It was really difficult to build a receiver that had both high sensitivity and high selectivity.

Superhet to the rescue!

The solution was the superheterodyne (superhet for short) receiver, invented around 1930. This idea revolutionized radio; all modern receivers use it.

Fig. 9 shows the block diagram. The amplification in the circuit is provided in three separate sections: the RF section, which extends from the antenna to the mixer; the IF section, which goes from the mixer to the detector (and is the main feature of the superhet); and the AF section, which extends from the detector to the speaker.

As before, the RF section contains some RF tuned circuits and amplifiers, which amplify the radio frequency signal. Similarly, the AF section contains some audio amplifiers, and amplifies the audio signal. Between them is the IF or *intermediate frequency* section, which amplifies the signal, but also provides all of the selectivity for the entire radio.

The superhet solves both problems of the TRF design. First, the IF section operates at a different frequency from the RF section; moreover, the IF section stays tuned to the same frequency regardless of which station we listen to. So the tuned circuits in the IF section can be properly aligned in the factory to give the best bandpass curve, and they don't get retuned by the user.

Further, because the overall radio gain is split into three sections, each section's gain is smaller. With less gain, feedback from the output back to the input is less of a problem, and because each of the three sections—the RF, the IF, and the AF—operates at a different frequency, it doesn't matter if a signal from one section sneaks into another, since it just gets rejected.

So the superhet's great feature is that the signal in the IF portion of the radio stays at a constant frequency regardless of what station you tune to. This is done by *heterodyning* or *beating* two signals.

DETOUR

Heterodyning is so important to radio that we have to look at it some more. Consider the circuit shown in **Fig. 10**. We have a box containing some circuitry, and two inputs into the box: one a 100 Hz sine wave, the other a 1000 Hz sine wave. What comes out?

Assuming there is *something* inside the box (not just empty air!), the two input signals will usually, somehow, combine into the output. Electrical engineers will now explain that there are two main possibilities.

If the circuitry in the box contains only resistors, inductors, and capacitors, it is called a *linear* circuit. In linear circuits, the output is proportional to the inputs; there is nothing in the output which didn't come from the input. This is just a fancy way of saying that if 100 Hz and 1000 Hz go in, then only 100 Hz and 1000 Hz can come out.

If the circuitry in the box also contains some diodes, transistors, tubes, or other *nonlinear* components, then this becomes a whole new ball game—things can come out that didn't go in.

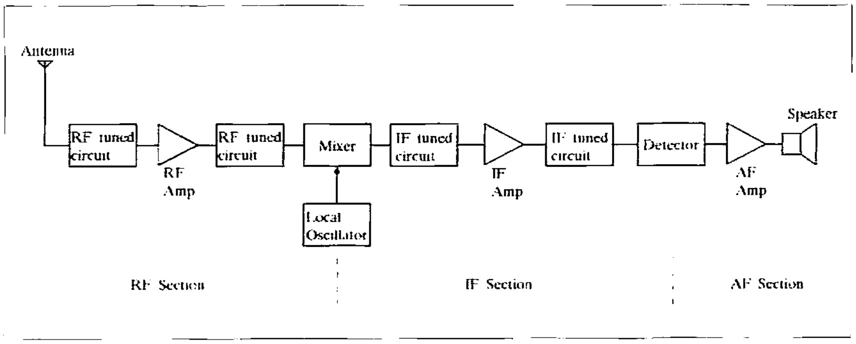

Fig. 9. The superheterodyne receiver block diagram.

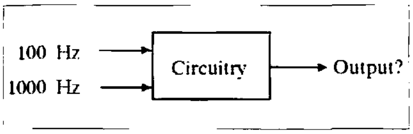

Fig. 10. Mixing two signals in some circuit.

For one thing, nonlinear circuits can distort; they can change the wave shape of the sine waves going in. As we explained way back at the beginning, this introduces harmonics. So the 100 Hz signal could now produce harmonics of 200, 300, 400, or more Hz, while the 1000 Hz signal could now have harmonics at 2000, 3000, etc. Hz.

Much more important for us, though, is that the two input signals can interact with each other. This process is called *heterodyning* or *beating*. When two signals interact like this, they produce new signals whose frequencies are the *sum* and *difference* of the original two signals. In our case, the sum would be 1100 Hz (1000 plus 100), and the difference would be 900 Hz (1000 minus 100). These new frequencies would be called *heterodynes*.

As usual, things are just a bit more complicated. The distortion harmonics also produce sums and differences. For example, the 200 Hz harmonic of the 100 Hz signal could heterodyne with the 3000 Hz harmonic of the 1000 Hz signal to produce 2800 and 3,200 Hz, and so on. Fortunately, the harmonics are usually smaller than the fundamentals, and so these heterodynes are also smaller than the main ones at 1100 and 900 Hz.

At a first glance, you may think this heterodyning is a terrible complication but remember that, without heterodyning, the superheterodyne receiver would be impossible, and radio and TV reception would be a lot worse today.

END OF DETOUR

Let's now see how heterodyning is used in the superhet. As an example, **Fig. 11** shows a superhet AM radio tuned to a radio station at 880 kHz. Coming in the antenna is not just this station, but also signals from all sorts of other stations—radio, TV, radar, etc. The tuned circuits in the RF section remove most of the undesired signals, but not all, so that the signal coming into the mixer is mostly 880 kHz, but still has many other signals.

The mixer is a nonlinear circuit; it receives this combined signal, but it also gets a 1335 kHz signal from the oscillator below it. Since it is nonlinear, it heterodynes these signals. There are a lot of different signals going in so it produces a lot of heterodynes, but the most important ones are the sum and difference of the desired station at 880 kHz, and the oscillator signal at 1335 kHz. This gives us 2215 kHz, the sum, and 455 kHz, the difference.

Note that the tuned circuits in the IF section are all tuned to 455 kHz, so they keep the 455 kHz signal and reject the others. By the time the signal gets to the detector, the filtering has been pretty much completed, and the signal is almost purely 455 kHz (plus the nearby sidebands).

Now, suppose we retune the radio to a different station, say one at 770 kHz. We retune the RF tuned circuits, but these only do a rough job of removing faraway signals; they aren't the main tuned circuits in the radio, so it isn't important to get them just right. But—and here is the important thing to note—we also retune the oscillator to 1225 kHz. The difference between 1225 kHz and 770 kHz is again 455 kHz! So the IF section amplifies the resulting signal, without having to be retuned itself.

The trick when changing stations is to retune the RF circuits (but a slight error here isn't critical), and the oscillator (this is important!) so the difference in frequency between the station you want and the oscillator stays at 455 kHz. Since the RF tuning adjustment isn't that critical, it is possible to use a single knob to adjust all the tuned circuits at the same time, without having to worry about whether all of them are right on target.

In case you wonder why we chose 455 kHz for the IF frequency... well, other values are possible, but this just happens to be a popular one in AM broadcast receivers. FM broadcast receivers usually use 10.7 MHz IF, and other IF frequencies are also used in other kinds of receivers.

If we let $f_{station}$ be the frequency of the station we want, and f_{IF} be the IF frequency, then the oscillator frequency f_{osc} should be:

$$f_{osc} = f_{station} + f_{IF}.$$

But it's also possible to let

$$f_{osc} = f_{station} - f_{IF}.$$

Either way, the difference between $f_{station}$ and f_{osc} is equal to the IF frequency f_{IF} so either will work.

The converter

Many radios combine the mixer and the oscillator into one circuit called the *converter*. This is a popular technique for lowering the radio's cost, because several components in the circuit do many jobs at the same time. **Fig. 12** shows the converter used in many popular AM broadcast radios; there are several useful techniques that are worth mentioning.

L1 and C1 are the RF tuned circuit, with C1 being the tuning capacitor, but L1 does several different jobs. The top part of the winding (above the ground connection) is the part that actually resonates with the capacitor; the bottom part (connecting to C2) acts as the secondary of a transformer, to bring the signal from L1 to the transistor without loading down the tuned circuit (which would reduce the Q).

At the same time, L1 is also the antenna. As we will see later, coils or loops of wire can act as antennas; in this case, L1 is wound on a ferrite core (a ceramic core which contains ferrous metal particles); the core helps to pick up the energy from the radio signal, and concentrate it in the coil.

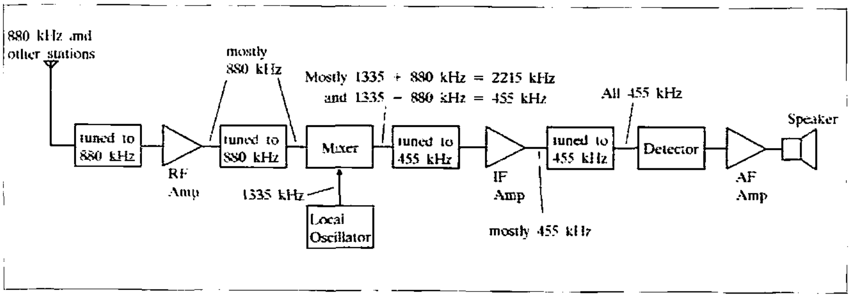

Fig. 11. Superhet with a 455 kHz IF, tuned to 880 kHz.

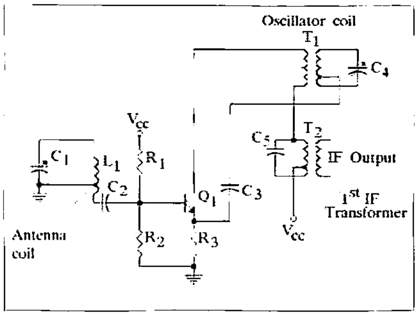

Fig. 12. Typical converter in an AM receiver.

The transistor also does two jobs. First, it oscillates at a frequency 455 kHz above the signal you want to pick up. To do this, we need an amplifier with positive feedback. The transistor is the amplifier, with its output coming out of the collector, going through oscillator coil T1, and back through C3 into the emitter of the transistor. Capacitor C4 resonates with the secondary of this coil to control the oscillator frequency.

At the same time, however, the transistor amplifies the RF signal coming from the antenna coil, and mixes it with the oscillator signal. Because the transistor is nonlinear, it also produces the sum and difference heterodyne frequencies. The primary of IF transformer T2 and capacitor C5 resonate at 455 kHz, and send the 455 kHz difference frequency on to the IF amplifier.

Note how T1 and T2 both use taps on one winding (the tap is a third connection part way into the winding). This reduces the loading on the resonant circuit, and keeps the Q from being lowered.

Variations on a theme

Although **Fig. 9** showed one RF amplifier (with two RF tuned circuits), and one IF amplifier (also with two IF tuned circuits), there is nothing sacred about these numbers. Many cheap radios use only one RF tuned circuit, and no RF amplifier; the converter shown in **Fig. 2** is a good example.

On the other hand, more expensive radios might have more RF amplifiers and/or more IF amplifiers. In fact, quite a few radios use *double conversion*. In this scheme, there are two mixers and oscillators (or two converters), and two different IF amplifier sections. We'll see the reason for this in a moment.

Superheterodyne sensitivity and selectivity

By splitting the amplification into separate sections, a superhet can provide more gain in each section without the danger of signals feeding back and causing oscillation. Further, because the IF amplifier does not need to be retuned each time you change stations, it can be optimized and carefully adjusted at the factory to provide the best possible bandpass characteristics—steep skirts and a flat top. But, there is more to it than that.

Recall our definition of the Quality factor Q of a resonant circuit:

$$Q = \frac{\text{resonant frequency}}{\text{BW, the 3-dB bandwidth}}$$

The 3-dB bandwidth doesn't really specify how well the circuit will reject adjacent stations; in order to reject such interference, the response of the tuned circuit has to be 30, 40, or even more dB down from the top of the curve at the frequencies of any adjacent stations. Still, it provides a useful yardstick for comparison.

"Just picking up a station is not enough if the station is so noisy that it is not pleasant to listen to."

We can rewrite the above equation as:

$$\text{3-dB bandwidth BW} = \frac{\text{resonant frequency}}{Q}$$

To get a small bandwidth, you have to either make the resonant frequency small, or make the Q big, but in most resonant circuits, there is a limit to how big Q can get. It is affected by the resistance of the rest of the circuit, and is seldom more than 20 or 30. So making Q big is not a feasible approach to making the bandwidth small. To get a small bandwidth, it would help if you could make the resonant frequency small.

In a TRF receiver, though, you must tune the resonant circuits to the frequency of the station you want to receive, so you really can't make the resonant frequency small to get a good bandwidth. To further complicate the design, the bandwidth will change as you tune to different stations.

In a superhet, on the other hand, all the selectivity is obtained in the IF stages, and their frequency stays the same for all stations. Moreover, the IF frequency is lower than *any* of the stations you want to receive, so you can get the same narrow bandwidth for every station you listen to. In theory, at least, you could get the bandwidth as narrow as you want, simply by going to a lower IF frequency. (Note how AM broadcast radios, which need a lower bandwidth than FM broadcast radios, also have a lower IF frequency of 455 kHz instead of 10.7 MHz.) But there is a fly in the ointment, as they say—the image.

The image

Let's return to the radio diagrammed in **Fig. 11**. It is tuned to 880 kHz, has a 455 kHz IF, and an oscillator frequency of 1335 kHz. Here we see that 1335 kHz - 880 kHz = 455 kHz.

So far, so good, but suppose there was a station at 1790 kHz. Look at the following calculation:

1790 kHz - 1335 kHz = 455 kHz

In other words, the difference between the new station at 1790 kHz and the 1335 kHz oscillator frequency is *also* 455 kHz. This new radio station could also now be heard, though not as well as the one at 880 kHz because the RF tuned circuits largely remove it. If it were strong enough, though, it would come through anyway. The 1790 kHz frequency is called the *image frequency*.

Note how the image frequency is calculated:

Desired station	880 kHz
+ IF frequency	+445 kHz
Oscillator frequency	1335 kHz
+ IF frequency	+455 kHz
Image frequency	1790 kHz

That is, the image frequency f_{image} is

$$f_{image} = f_{desired\ station} \pm 2f_{IF}$$

(We used the ± sign in the equation because in some radios the oscillator could also be below the desired station

frequency; in that case, the image frequency would be below the oscillator frequency, and we would need the minus sign.)

This brings us to a problem. Just a few paragraphs ago, we said "In theory, at least, you could get the bandwidth as narrow as you want, simply be going to a lower IF frequency," but if you do that, then the image frequency gets closer to the desired frequency, and then the RF tuned circuits may not be able to get rid of it. So you have two conflicting requirements:

To get better selectivity—lower bandwidth—you want to *lower* the IF frequency.

To get better rejection of the image frequency, you want to *raise* the IF frequency.

This is particularly a problem with high-frequency receivers intended to receive narrowband signals. For example, consider an amateur FM receiver for 146.94 MHz. Since the bandwidth of FM signals on this frequency is typically only 10 or 15 kHz, a low IF frequency (such as 455 kHz or even less) would be ideal. But then the image would be at:

$$146.94 \text{ MHz} + (2 \times 455 \text{ kHz}) = 147.85 \text{ MHz}$$

which is not even 1% away from the desired frequency. There is no way that a typical RF tuned circuit could keep the image out—you'd need a tremendous Q to do it.

Typical receivers solve the problem in one of two ways. A few use a much higher IF frequency (around 10 MHz), but with special crystal or ceramic filters which can get the narrow bandwidth even at this higher IF frequency.

A much more common alternative is to use two separate IF sections and double conversion. **Fig. 13** shows the block diagram of a double-conversion superhet to receive 146.94 MHz. Since 10.7 MHz and 455 kHz IF transformers are fairly inexpensive (they are manufactured by the zillions for use in standard AM and FM broadcast receivers), many communications radios use them as well, and we show them here.

To receive 146.94 MHz, the first oscillator runs at 146.94 minus 10.7 MHz, or 136.24 MHz (the oscillator could be either 10.7 MHz *above* the desired signal, or 10.7 MHz *below*; in this case, we chose to use the lower frequency). The second oscillator and mixer convert the 10.7 MHz first IF signal to 455 kHz by using an oscillator at 10.7 MHz + 0.455 MHz, or 11.155 MHz.

By using two IF frequencies, the double-conversion receiver solves our two problems. The high first IF frequency does not provide much selectivity, but it helps to eliminate the image. Since the image frequency is at:

$$f_{image} = f_{desired\ station} - 2f_{IF}$$

(Note that we use a minus sign since the oscillator is below the desired signal, so the image must be even below that.) The image frequency is now:

$$146.94 \text{ MHz} - (2 \times 10.7 \text{ MHz}) = 125.54 \text{ MHz}$$

which is far enough away from 146.94 that the RF tuned circuits can remove it (or at least significantly reduce it).

The second IF frequency of 455 kHz, on the other hand, is low enough so that even transformers with reasonable Q can provide a narrow bandwidth.

Incidentally, suppose we wanted to use a similar circuit to receive 145.015 MHz instead of 146.94 MHz. This circuit would not do, and for an interesting reason: The 11.155 MHz signal from the second oscillator goes into the second mixer, and the mixer is intentionally nonlinear (to produce a heterodyne). Hence, it also generates harmonics of all the signals going in. It turns out that the 13th harmonic of 11.155 MHz is exactly 145.015 MHz. Although this harmonic is weak, a small amount of it will still sneak back into the RF stage and fool the receiver into thinking there is a weak, unmodulated signal at that frequency. Unless your desired signal is substantially stronger than this false signal (called a *birdie*), it will not be heard.

The solution in this case is to change the second oscillator frequency from 10.7 *plus* 455 kHz to 10.7 *minus* 455 kHz, or 10.245 MHz. This new oscillator frequency has harmonics at different places. While this removes the birdie at 145.015 MHz, it introduces birdies elsewhere, such as 143.43 (which is the 14th harmonic of 10.245 MHz). Designing wideband receivers (receivers designed to receive a wide range of frequencies) is always a problem; there are always some birdies somewhere, and the designer has to carefully choose his oscillator and IF frequencies to try to place the birdies at places where they will not interfere with normal operation.

Summary

If the superheterodyne receiver had never been invented, communications as we know it would probably not exist. The combination of features we have described allows radio receivers to have selectivity and sensitivity, letting millions of transmitters around the world coexist with each other while making it possible for us to select and listen to even extremely weak signals from far away.

We have touched on some of the important concepts, yet have had to skip many others. In the next installment, we will try to cover some more concepts having to do with the transmitters and receivers which we run into daily. 73

Pursuit of 2304 MHz: local oscillator and filter

Last month I discussed using a Qualcomm 3036 phase-locked loop (PLL) synthesizer as the backbone for construction in the microwave arena. This synthesizer has enabled our microwave group to construct several converters for different microwave bands, using surplus material, for local oscillator generation. A synthesizer is not perfect, as we stated last month, but it is perfectly acceptable when it's inexpensive and performs well. After all, that's the basic premise for most amateur-related projects: low cost and suitability. After that can come the pursuit of excellence, and gold-plating.

I know that the subject of synthesizers can be a little intimidating but I will try to remove some of the mystique, showing that they can be easily modified. Additionally, the waveguide below cutoff filters that we constructed and used in our transverters will be covered for use at 1296, 2304 and 3456 MHz. I will describe the transceivers that our club members constructed. This was a rush-to-completion project so we didn't use all the bells and whistles. One quick item that was put to use to demonstrate this operation was the filter construction. These filters are not the ultimate, but they are easy and inexpensive to construct and are tolerant of mistakes. This makes a very simple package to assemble with other components to facilitate a microwave converter. Let's cover the synthesizer first.

The synthesizer

The Qualcomm 3036 synthesizer chip is the heart of this circuit. This little chip can directly control a voltage-controlled oscillator (VCO) up to 1.6 GHz by itself, with minimal external circuitry. Equipping it with an additional divide-by-two frequency divider chip (on the PC board) will extend the VCO towards the 3 GHz range. This is the reason the synthesizer that we make available is capable of working directly at 2556 MHz and other frequencies above the 1.6 GHz frequency range of the synthesizer chip.

Other circuitry on the synthesizer board includes the loop filter and clock reference circuitry. The clock used in this application is a very high stability 10 MHz temperature-compensated crystal oscillator, or TCXO for short. The oscillators we use are capable of stability of .1 hertz at 10 MHz or better over temperature.

The 3036 synthesizer chip can be programmed by an IBM 8-bit computer bus, or it can be pin-for-pin programmed in a fixed mode of operation. While the IBM bus mode might be attractive to some serious experimenters wanting to push for other developments, most applications will fall on the basic pin-for-pin manual programming methods that we have developed for single-frequency amateur frequency generation. It is in this fixed mode that all of the amateur frequencies were generated for use at the 2 to 2.7 GHz frequencies for local oscillator use. Multiplication schemes were employed for use at 3456 MHz, 5760 and 10368 MHz. All these schemes used manual pin-for-pin programming.

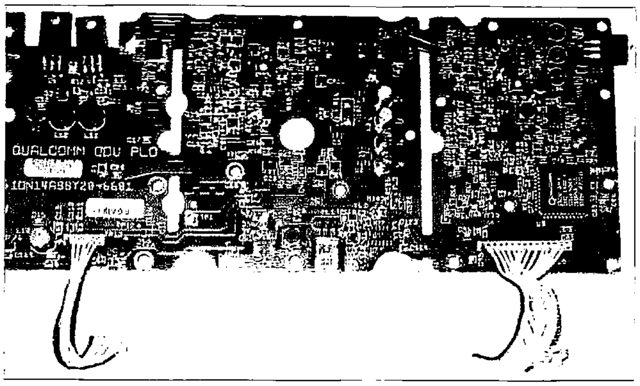

Photo B. Qualcomm power supply synthesizer board before conversion. The left and middle parts of the PC board have been removed, leaving a cigarette pack-size PC board containing all the synthesizer circuitry.

The IF frequency we have chosen to use is 2 meters, making a local oscillator frequency of 2160 required for 2304 MHz. That is, 2160 MHz plus 144 MHz equals 2304 MHz, the operating frequency. Other IF frequencies are possible. The synthesizer as originally used in commercial operation required a frequency of nearly 2.6 GHz and was controlled by an on-board processor (the IBM single-chip 8-bit controller). Pin 22 is the mode select pin of the 3036 chip and is grounded for bus mode and tied to +5 volts for pin-for-pin programming.

Modifying the 3036

Gently cut pin 22 at the board solder trace with a sharp Exacto™ knife and lift the pin from the PC board solder pad nearly horizontal for wiring to +5 volts. In this same manner lift the other pins with the knife to provide for pin-to-pin reprogramming. It might sound difficult, but the conversion is easy; it just requires a delicate smooth operation. A heavy-handed method of operation here will break the pin and render the chip useless.

If you take care and lift the pin with easy slow movements and do not apply force, the pin can be lifted without breaking it. Lift it just enough to allow soldering to the new programming control, which is either ground or +5 volts, as determined by the frequency reprogramming chart shown in **Table 1**. If you are heavy-handed with the knife when lifting the chip pins they will break off and the chip will be gone. Gentle lifting of the pin works well. Do not try to move the pin more than once as it might weaken and break off. Also, don't try to make the pins uniform or "pretty them up," as excessive movement could also break the IC pin off flush with the IC.

Let's discuss the internal structure of the 3036 chip so you can get some idea of just what is going on inside. The Qualcomm 3036 PLL has three counters internal to the chip: the 7-bit "M" and 4-bit "A" pulse swallow counters, and a 4-bit reference counter. All of these programming pins must be configured to our new programming information, along with four control pins (some of the pins are already tied to the correct ground or +5 volt connections and do not have to be changed). **Fig. 1** shows a schematic of the complete assembly.

To modify the synthesizer, you will need a grounded static-free work station equipped with a temperature-controlled soldering iron, an Exacto knife, and a small

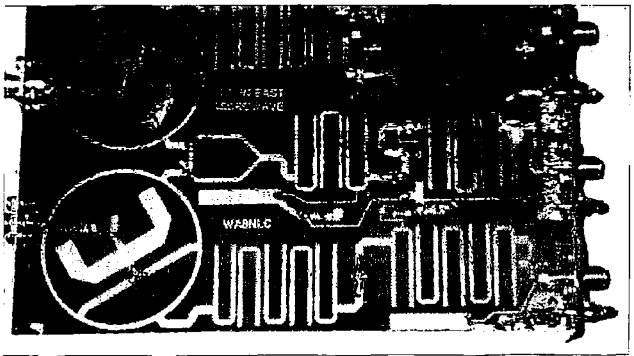

Photo A. 2304 MHz transverter from Down East Microwave, built by Pete W6SAJ.

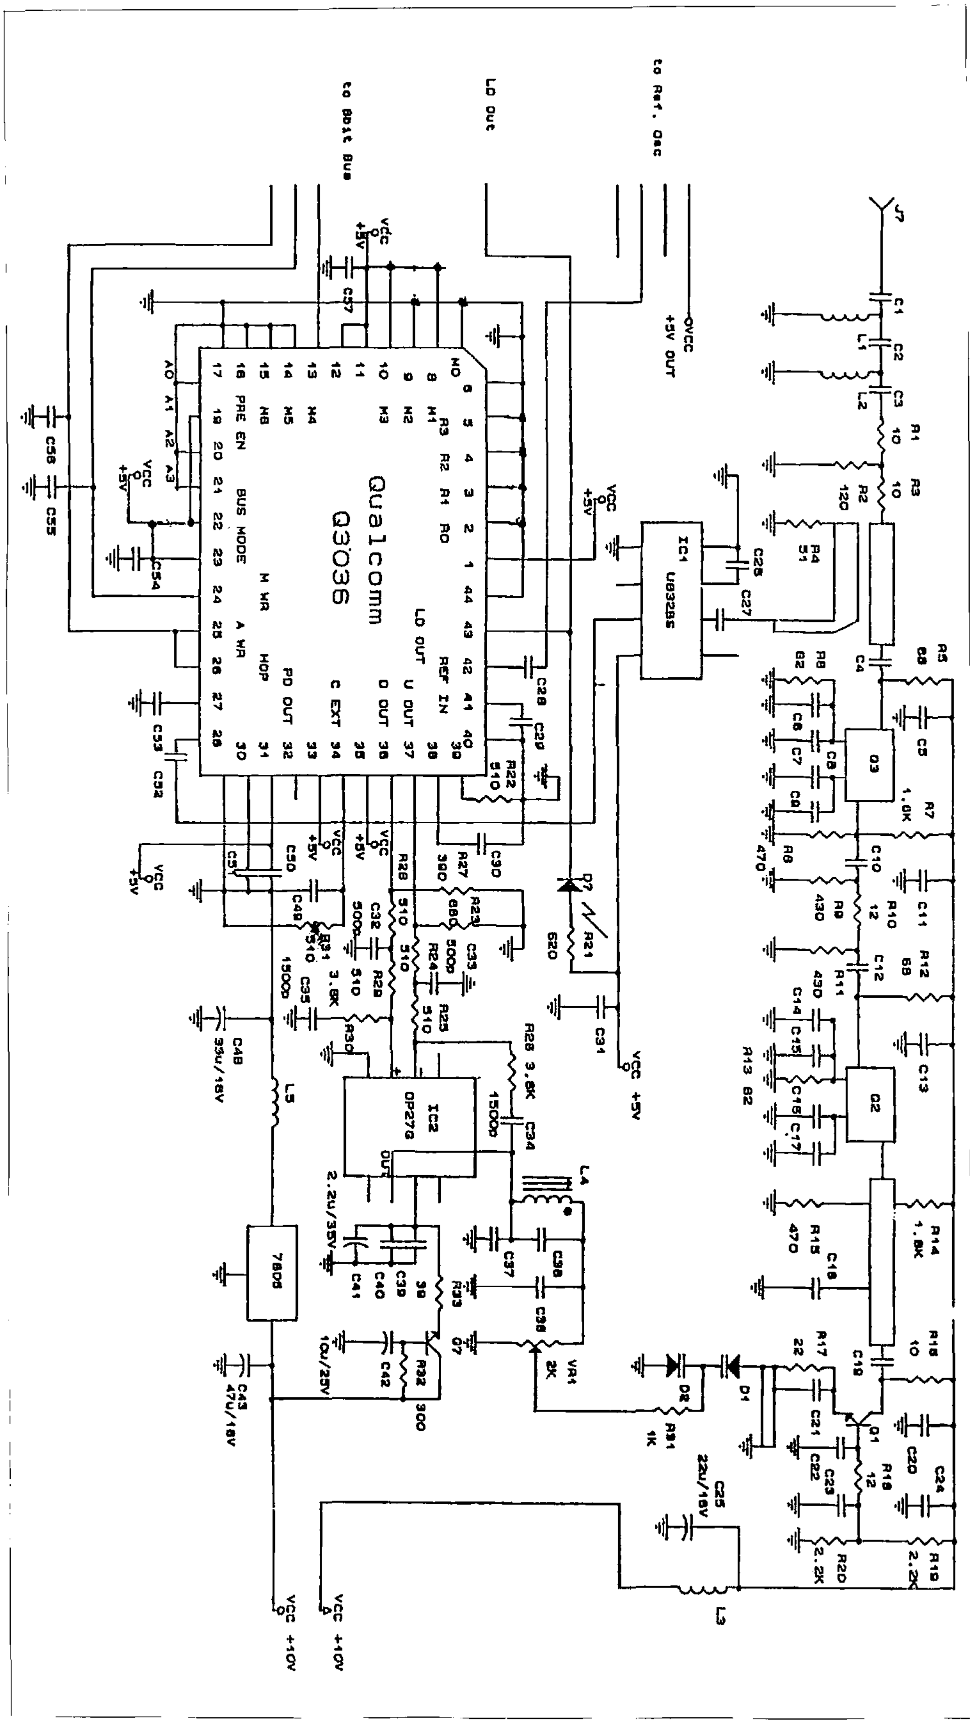

Fig. 1. The Qualcomm 3036 synthesizer chip and its schematic diagram. This was reverse engineered by Kiyotsugi Tanemura JG1QGF.

magnifying lens to examine your progress. The circuitry is quite tolerant to soldering and handling abuse. Don't get me wrong here—I don't recommend mishandling the synthesizer, as it is a high density PC board using very small surface-mount components. It has proven to be quite abuse-resistant, but don't push your luck by mishandling it. Use a temperature-controlled soldering iron that is grounded, and work in a static-free setting. This will prevent static and other voltage-induced problems from damaging chips on the PC board. Do not use a high-heat soldering iron as the excessive heat can lift the PC board copper foil by breaking the bond between the copper trace and the PC board.

To reprogram the 3036 synthesizer chip we used an Exacto knife with a sharp blade and carefully cut the pins of the 3036 (at the PC board) that needed to be lifted to suit our particular reprogramming information. The stock PC board as received was set up for programming by a CPU located on another PC board and connected by the board connector located just above the 3036 chip. (The boards that I make available are pretested by connecting a processor using the stock programming frequency of 2620 MHz.)

In the PC boards that I make available there may be parts of the PC boards that are jumpered around, such as power supply, and other troubles. These "other troubles" have no bearing on the synthesizer operation as most of these trouble spots occur where some of the circuitry has been removed in the modification to amateur frequencies. The cable that connects to the processor is removed along with the processor. This leaves many of the pins of the 3036 open. There are other pins that are tied to ground on the PC board, and some of these need to be lifted and tied to +5 volts. See **Fig. 1** for the pinouts of the 3036 synthesizer chip. **Table 1** shows pin programming for several frequencies commonly used.

The remainder of the conversion consists of reducing the size of the PC board, removing the power and control circuitry that

Q 3036 Pin Assignment/Description

Pin #	Name	I/O Type	Description
1	V_{CC1}	+5V input	Power supply connection
2	R0 IN	TTL/CMOS input	R counter input bit 0 (LSB)
3	R1 IN	TTL/CMOS input	R counter input bit 1
4	R2 IN	TTL/CMOS input	R counter input bit 2
5	R3 IN	TTL/CMOS Input	R counter input bit 3 (MSB)
6	GND	GND	Ground connection
7	M0 IN (DBUS0)	TTL/CMOS input	M counter input bit 0 (LSB), data bus bit 0 (LSB)

43	LD OUT	TTL output	Open collector lock detector (O.C.=in lock)
44	GND	GND	Ground connection

Table 1. *Pin programming for changing the frequency of the Qualcomm 3036 synthesizer chip.*

is not required. You can prepare the circuit board with modifications first, then cut off portions of the board that are not required.

There is a C2610 +10 volt regulator (TO-220 package) that is part of the power supply circuitry. It can be removed and used to power the modified synthesizer. There are two traces on the bottom of the synthesizer board: a small one and a large wide trace. The wide trace is the +10 volt input to the +5 volt regulator for the 3036 chip. The small trace is the +10 volts for the oscillator amplifier buffer string. Short these two traces together and tie to regulated +10 volts from the C2610 device. On top of the board there are four traces going over the top portion of the board's cutout. Leave this circuitry in place, along with the crystal and chip circuit to the right. On the far right of the 10 MHz crystal filter there is an attenuator pad "T" configuration. This is the 10 MHz reference input. All circuitry to the right and below the 10 MHz filter can be removed.

If you have trouble finding the 10 MHz input pad, start at the far-right part of the PC board before cutting it. There you will find two off-board connections. The bottom one is the +12 volt main input to the power distribution and regulator circuit. The top one is the 10 MHz input and connects directly to this pad to use when you reduce the size of the synthesizer PC board. You might select to leave the PC board intact; that's OK—it's your option whether to have a smaller PC board or keep it at the original size.

General Equations

Table 2B. *3036 PLL IC Pinout (top view of chip). The table lists pin designations along with the proper wiring for 144 MHz IF/2556 MHz VCO operation.*

The board can be cut near the bottom cutout where we tied the two traces together, and just above the four capacitors to the right of the top cutout. Cut near the ground foil beneath the PC board traces. You can retain part of the PC board if you desire. This will retain a very good -5 volt bias circuit using a 7660 chip. The other control circuitry is not of interest to an amateur conversion of the synthesizer power supply control board as it was originally built. This conversion removes the essential oscillator synthesizer, reducing of the board real estate to a smaller package. See the accompanying photos for details on the conversion.

Consult **Table 2A** for pin programming information covering a few standard frequencies. Many frequency combinations are possible in the 2.16 to 2.6 or so GHz range using the stock VCO on the board. The board is set up to work with a reference divided frequency of 1.25 MHz. Note that other reference frequencies are possible, such as 2 MHz. All that is required is to reset the "A" reference counter. Before lifting the 3036 pins I suggest you make a paper drawing of your attack plan on how and which pins to lift. (See **Table 2B**.) A little planning in this area will help to familiarize you with the methods of conversion to prevent errors.

When you have lifted all required pins, test each pin for proper DC resistance between either ground or the +5 volt line, as required according to the frequency modification chart, with a VOM. Set the VOM to the X10 scale to verify all pins before and after modification and before applying power. This should bulletproof the modification procedure for errors. When you are satisfied that all is well, connect a source of 10 MHz (1 volt P/P) to the input of the attenuator pad by the 10 MHz filter and apply power. There is an LED phase-lock indicator on the PC board. If all is well it should blink on then off, indicating proper phase lock.

Once you have verified phase lock and output power you can verify output frequency and power. Normally we see about +8 to +10 dBm power output.

Originally we made a modification to the circuitry in the phase detect balance circuit but we found that the circuit is best left alone. Rather, what needs to be done is to modify the output loop filter for the proper values required for the new division divide-by frequency. This loop filter consists of a parallel LC filter shunted to ground with two capacitors. This network is normally set to 1.25 MHz.

The loop filter is converted by changing the filter capacitor component values. To convert it to our new reference frequency add a .001 μF capacitor across the LC filter and add .003 to .004 μF as additional shunt capacitance. The best way to change these values is to piggyback additional capacitors across the existing lower-than-required values. This filter is tied directly to pin 6 of the OP-27 op amp output.

Microwave filter construction

The filter that we constructed for these three bands is an evanescent mode filter, or just call it a waveguide filter below cutoff frequency. It is constructed out of a short section of waveguide of no particular size except for the general rule of thumb: A 10 to 12 GHz waveguide with an opening approximately 1/2"-by-1" is good for the frequency range of 1 GHz to about 3.5 GHz. The filters that I constructed were attempted by selecting components that seemed to suit the frequency of interest knowing the results of my first construction attempt.

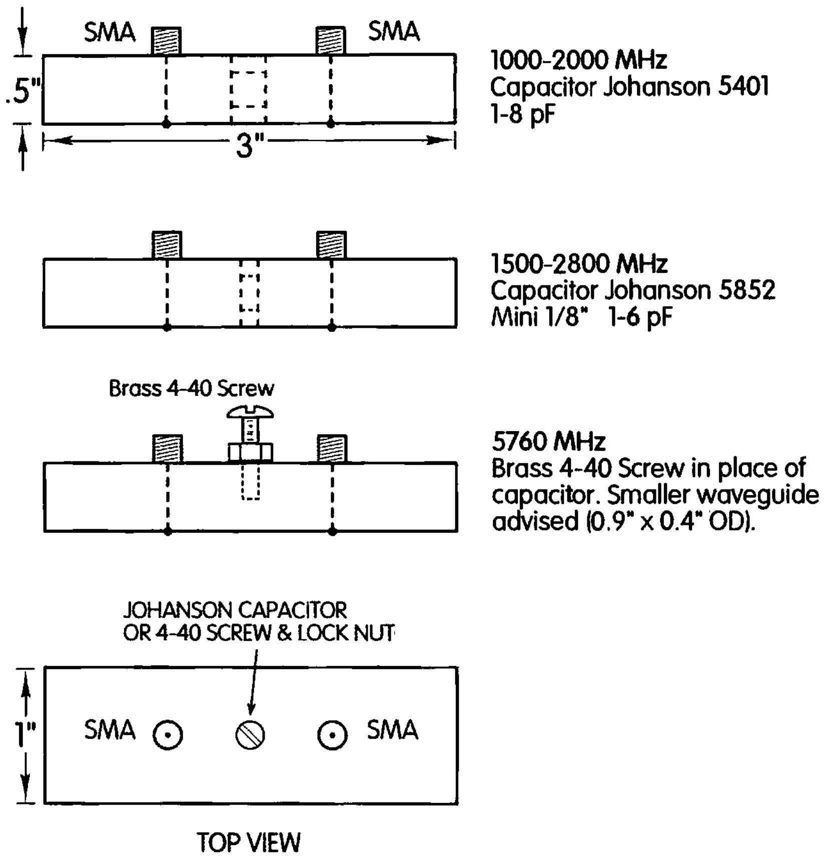

Fig. 2. The 2304 filter using WG-16 1" x 1/2" OD waveguide, and details for other frequencies up to and including 5760 MHz.

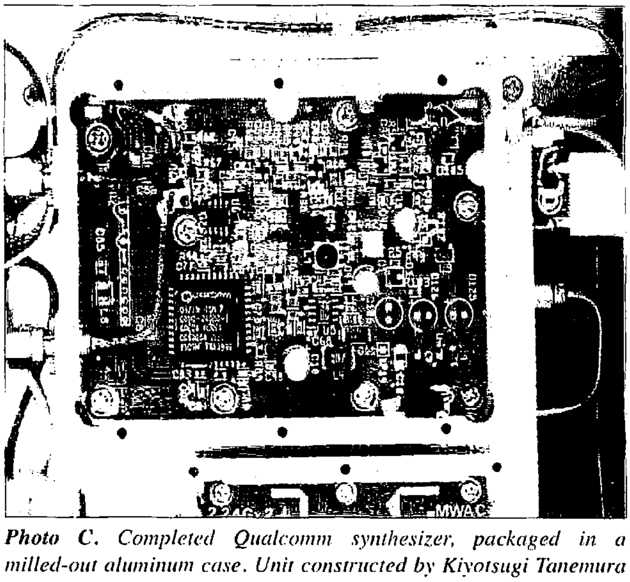

***Photo C.** Completed Qualcomm synthesizer, packaged in a milled-out aluminum case. Unit constructed by Kiyotsugi Tanemura JG1QGF in Japan. This is a premium high-quality conversion that anyone would be proud to have constructed.*

My first attempt was to use a Johanson 5481 1-to-8 pF variable and soldering it between the top and bottom of the waveguide. Coax connectors were spaced 1/2 inch on either side of the capacitor to serve as the input and output ports of the filter. It was no trouble to resonate this filter at 1296 MHz, but the upper frequency was limited to about 2 GHz. Constructing a similar filter but replacing the capacitor with a smaller width (1/8 inch) version of the Johanson capacitor vs. the 5481, which is 1/4 inch wide, made resonance at 2304 and 3456 feasible. Moving on to 5760 was impossible with even the smallest variable I had so we tried a small 4/40 bolt in place of the capacitor. This, while very critical, worked well.

Use a lock nut on the 4/40 bolt (brass nut and bolt) and when it is tuned, lock it with the nut. See **Fig. 2** for the mechanical details. Waveguide rule of thumb: For frequencies in the 1 to 2 GHz range, a waveguide with a 1 inch by 1/2 inch outside diameter is acceptable. For higher frequencies, use the next size smaller waveguide, with dimensions near .9 inch by .4 inch wide.

Well, that's it for this month. I hope that this column is not rushed too much as I am working seven days a week and have little time off for any activities. Pacific Bell, the company I work for, is the prime provider for video operations for the Republican Convention in San Diego and it has me very busy. On another note, I am held up on sending out 30 MHz kits as the supply of TDA-7000 chips is depleted and the new order has not arrived. Please be patient as the orders *will* be filled. Best 73 always, Chuck WB6IGP.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 30. Provide a clear, concise summary of the essential details about your Special Event.

SEP 22

MT. HOLLY, NJ The 80th Anniversary of the South Jersey Radio Assn. will be celebrated at Mt. Holly Armory, Rt. 38. The 48th annual Hamfest Computer Show will be held rain or shine, 8 AM–3 PM. Vendor setup 5:30 AM. VE Exams, tailgate sales, seminars. Make checks payable to South Jersey Radio Assn. Inc., and mail with SASE to *Paul E. Hayden KF2YX, 519 North Elmwood Rd., Marlton, NJ 08053.*

OCT 11–13

MESA, AZ The Scottsdale ARC will host the ARRL Southwestern Div. Convention at the Sheraton Mesa Hotel and the Mesa Conference Center. For details, contact *Barbara A. Myers KB7UKD, Exhibit Chairperson. P.O. Box 17108. Fountain Hills AZ 85269-7108. Tel. (602) 837-6492. or FAX (602) 837-6872.*

OCT 12

ALPENA, MI Hincks Elementary School, 7 mi. north of Alpena, on US-23N, will be the site for the Thunder Bay ARC Hamfest. Computer Fair. and North Color Tour. VE Exams at 1 PM, walk-ins okay. Talk-in on 146.76 or 145.49. SASE to *P.O. Box 764, Alpena MI 49707.* For VE info or details, call *Tom K8CHS. (517) 354-2469.*

EVANS, GA The Augusta Hamfest will be held at Evans Middle School. Setup Fri., 6 PM–9 PM; Sat., 6 AM–9 AM. VE Exams start at noon on the 12th. Contact *Richard KR4XN at (706) 860-3828;* or *Rhonda KE4DIM at (706) 560-9600;* or write to *P.O. Box 3072, Augusta GA 30914.*

OCT 12–13

GERMANTOWN, TN MemFest 1996 Greater Memphis Amateur Radio and Computer Show will be held at Shelby Farms Show Place Arena, 105 Germantown Pkwy, Sat., 8:30 AM–4 PM; and Sun.. 8:30 AM–2 PM. RV camping on site. Forums and Non-Ham activities. VE Exams Sat. and Sun. 9 AM–11 AM. Gordon West WB6NOA will be Guest Speaker. Sponsored by the Greater Memphis Amateurs. Exhibitors contact *Mary Moore AC4GF, (901) 758-0661* or *Fax (901) 751-6717.* For Flea Market info contact *Lee Bowers KA4KVW at (901) 867-3461, after 6 PM.* Talk-in on 144.61/145.21 and M9. 17514M. 175.

OCT 13

CHICAGO, IL The Chicago ARC will hold a Hamfest in Oakbrook Terrace IL, 8 AM–3 PM. Setup at 6 AM. Entrance at Park View Dr., north from Cermak Rd. Talk-in on 147.255(+), and 444.825(+). Contact *George, (312) 545-3622; Dean, (708) 331-7764;* or *Cora, (312) 486-6823;* or write to *CARC, 5631 W. Irving Park Rd., Chicago IL 60634.*

LIMA, OH The Lima Hamfest and Computer Show will be held by the Northwest Ohio ARC. 8 AM–3 PM at Allen County Fairgrounds. Setup at 6 AM. Talk-in on 52/52, 146.07/.67, 146.34/.94, and 147.63/.03. To pre-reg. for VE Exams, send complete FCC Form 610. a copy of your old license, a check for $6.05 made payable to *NOARC,* and SASE to *License, c/o NOARC, P.O. Box 211. Lima OH 45802.* For tickets and table reservations, call *(419) 647-6321.* Mail SASE and payment to *NOARC, P.O. Box 211, Lima OH 45802.*

MASON, MI The Lansing Civil Defense Rptr. Assn. and the Central Michigan ARC will co-sponsor a Hamfair, 8 AM–1 PM, at Ingham County Fairgrounds in Mason, MI. Overnight camping available. Trunk Sales space, DX Forum. Vendor setup at 6 AM. Talk-in on 145.390. Contact *Jeff Oberg KB8SXK, (517) 393-4713;* or write to *LCDRA, P.O. Box 80106, Lansing MI 48908.*

QUEENS, NY The Hall of Science ARC Hamfest will be held at the New York Hall of Science parking lot, Flushing Meadow Park, 47-01 111th St., Queens NY. Setup at 7:30 AM, buyers admitted at 9 AM. Talk-in on 444.200 WB2ZZO Rptr., 146.52 simplex. For more info call at night only. *Arnie Schiffman WB2YXB. (718) 343-0172.*

OCT 18–20

CONCORD, CA The Mt. Diablo ARC is host for this year's "Pacificon." The event will be held at the Concord Hilton, 1970 Diamond Blvd. An Antenna Seminar will be held Fri. 8 AM–4:30 PM, pre-reg. required. A Swap Meet will be held Sat. and Sun. 6 AM–11 AM. with seller setup at 5 AM. The seller fee is $10 for both days. There will be Forums. walk-in VE Exams, vendor displays. a Boy Scout Special Events Station, T-hunt, and more, all day Sat. and on Sun. morning. Cynthia Wall KA7ITT will be Guest Speaker at the Sat. evening Banquet. An ARRL Forum will be presented Sun. afternoon. Talk-in on 147.060 + 100. For info, call *(510) 932-6123;* or write to *Pacificon '96, P.O. Box 272613, Concord CA 94527-6125. E-mail: PACIFICON@DESIGNLINK.COM.*

OCT 19

SENECA, PA The Venango Mike and Key Club will hold a HamAuction 8 AM–3 PM at Christian Life Academy in Seneca. Setup at 6 AM. VE Exams at 9 AM. Talk-in on 145.230(-). For reservations contact *Mary Housholder N3QCR. 121 N. Front St., Franklin PA 16323. Tel. (814) 437-2036. Packet: N3QCR@WA3ZCA.#NWPA. E-mail: mahoushold@aol.com.*

OCT 20

CENTRALIA, IL The Centralia Wireless Assn. will host its annual Hamfest at the Salem Community Activity Center, East Oglesby St., Salem IL, starting at 8 AM. Talk-in on 147.27/.87 MHz. Setup for Exhibits and Flea Market will be at 6 AM. For table space and reservations. contact *Daisy King AA9EK, (618) 532-6606.* Mail ticket orders with an SASE to *Centralia Wireless Assn., Inc., Hamfest Tickets. P.O. Box 1166. Centralia IL 62801.*

GOLDEN, CO The 1996 Rocky Mountain Radio League Hamfest will be held 8 AM–2 PM at the Jefferson County Fairgrounds. 15200 W. 6th Ave. Talk-in on 144.62/145.22. The event will feature VE Exams and an ARRL Forum. For info, call *Joe Dickinson WTØC, (303) 771-9577.*

KALAMAZOO, MI The Kalamazoo Hamfest Assn. will present the 14th annual Kalamazoo Hamfest at the County Fairgrounds. Doors open at 8 AM. Trunk sales. Vendor setup at 6 AM. Camping available on site. For more details, call the info hot line at *(616) 657-4482.*

MILLER PLACE, NY "HAMEXPO 96–ARRL Hudson Div. Convention" will be held at the Huntington Hilton Hotel, 595 Broad Hollow Rd., Melville NY. Call *(516) 845-1000* for reservations. The Ham Expo will be open to the public 9 AM–4 PM. Vendor setup at 7 AM. There will be VE Exams and an ARRL Forum. Write to *Radio Central ARC, P.O. Box 680, Miller Place NY 11764. Tel. (516) 399-1877 (Joann N2IME). or E-mail N2MDQ@LI.NET.*

SELLERSVILLE, PA A Hamfest hosted by the RH Hill ARC will be held at Sellersville Fire House, Rt. 152, 3 mi. south of Quakertown and 8 mi. north of Montgomeryville. VE Exams start at 9 AM for all classes. Bring documents. Talk-in on 145.31. Contact *Linda Erdman. P.O. Box 29. Colmar PA 18915. Tel. (215) 679-5764.*

OCT 26

PORT ST. LUCIE, FL The Port St. Lucie ARA "Hamfest–96" will be held 8 AM–3 PM at Port St. Lucie Yacht Club. 500 Prima Vista Blvd. Talk-in on PSLARA Rptr. 146.955 or 146.520 simplex. For table rentals call *Rick Clair (407) 335-1738.* For general Hamfest info, call *Don Metzler (407) 879-4914.*

SALEM, OR The 2nd "SwapToberfest ARES/Races Convention," sponsored by the Mid-Valley ARES, will be held at the Polk County Fairgrounds in Rickreall OR. Setup will be 6 AM–9 PM Oct. 25th, and 7 AM Oct. 26th. Doors will be open for the convention 9 AM–3:30 PM. VE Exams, pre-reg. required; call *Sandy Berry N7TQQ at (503) 585-5924.* Registrations received Oct. 20 or later will be held for pick-up at the door. Emergency Comm. vehicles will be on display from the Oregon State Police, Marion and Polk County Emergency Management, the Civil Air Patrol, and the American Red Cross. For more info. contact *Evan Burroughs N7IFJ. (503) 585-5924.* To download a copy of the flyer and pre-reg. form, surf the net for *http://www.teleport.com/~n7ifj.*

ST. LOUIS, MO The Gateway to Ham Radio Club, and the St. Louis ARC will sponsor the 5th annual Halloween Hamfest at West County Tech. School. Vendors' doors open 4 PM–9 PM Oct. 25th, and 6:30 AM Oct. 26th. The event is open to the public 8:30 AM–2 PM. Flea Market, forums, VE Exams. Wheelchair accessible. For advance tickets, SASE to *Dave NODN, 8370 Latty Ave., Hazelwood MO 63042*. For tables, contact *Keith NØKFE, 8427 Mathilda Ave., St. Louis MO 63123*. Talk-in on 146.34/.94.

ST. PAUL, MN The 12th Anniversary celebration of Hamfest Minnesota and Computer Expo will take place in the main arena at the St. Paul Civic Center, Kellogg & West 7th Sts., St. Paul MN. The event will be sponsored by the Twin Cities FM Club, and will have a huge Flea Market, VE Exams, educational and fun seminars, exhibits, and more. VE Exams and Flea Market setup will take place on Fri. night. Talk-in will be on the 146.16/.76 Rptr. For info and advance reg., contact *Hamfest Minnesota & Computer Expo, P.O. Box 5598, Hopkins MN 55343;* or call *Hamfest Minnesota Info Line at (612) 535-0637.*

SUMTER, SC The Sumter ARA's 10th annual Hamfest and Computer Fair will be held at Sumter County Exhibition Center, 700 W. Liberty St. Contact *Steve Bregger KD4HTS, P.O. Box 52302, Shaw AFB SC 29152-0302;* or *Mike Dunlap KC4HUT, 2763 Tindal Rd., Sumter SC 29150-8830. Tel. (803) 481-4611.*

OCT 27

WESTMINSTER, MD The 7th annual Mason-Dixon Computer & Hamfest will be held at the Carroll County Ag. Center in Westminster, beginning at 8 AM. Setup at 6 PM for vendors and tailgating. VE Exams start at 8 AM, pre-reg. requested; call *Bill Wolfgang NZ3J, (717) 359-7095.* Talk-in on 145.41(-). For inside tables and info. contact *George Johns N3JKY, (717) 632-1621.*

NOV 2

MILWAUKEE, WI The 12th annual "6.91 Friendlyfest" Ham Radio, Computer and Electronics Show will be held 8 AM–1 PM at Waukesha County Expo Center Forum, N1 W24848 Northview Rd., in Waukesha Wi. Vendor setup 5:30 AM–8 AM. Wheelchair-accessible. VE Exams onsite. Bring an original and 2 photocopies of your license and/or CSCE (if any) and 2 IDs, one must be a photo ID. Talk-in on 146.31/.91 Rptr. and 146.52 simplex. Contact *Burt N9VBI, (414) 328-0535* for further details.

TAVARES, FL The Lake ARA, Inc. will hold their Hamfest & Electronic Expo 8 AM–4 PM at the East Lake Chamber of Commerce in Sorrento FL. VE Exams at 10 AM, walk-ins okay. Vendor setup Nov. 1st, 3 PM–6 PM; Nov. 2nd, 6 AM–8 AM. Contact *Tony Summerlin KE4NLG, 9210 Fernery Rd., Leesburg FL 34788. Tel. (352) 360-1380.*

NOV 2–3

ODESSA, TX The 13th annual Odessa Hamfest will be held by the West Texas ARC Sat., 8 AM–5 PM and Sun., 9 AM– 2 PM, at Ector County Coliseum, Exhibit Bldg. C, 42nd and Andrews Hwy. Setup Fri., 4 PM–10 PM, and Sat. at 7 AM. Talk-in on 145.470. Contact *Robert Jordan N5RKN, (915) 335-7980; E-mail N5RKN@aol.com.*

SPECIAL EVENT STATIONS

SEP 21

BADIN, NC The Stanly County ARC will operate K4OGB during the "Best of Badin Festival." Operation will be in the lower General 40m–15m bands and 28.365, all phone. For a certificate, send a 9" x 12" SASE to *K4OBG, P.O. Box 581, Badin NC 28009 USA.*

OCT 1

Walt Disney World, Disneyland, Euro Disney, Tokyo Disneyland, and Capital Cities ABC New York. The parks will be operating on 20m, 40m, 75m, and 2m repeaters from 2230-1700 UTC. Look for them on these frequencies: Disneyland repeaters\146.94, 446, 1282.4—simplex 245.09, 144.3 as W6LPJ; Walt Disney World on a 2m repeater, channel not specified; ABC repeater 147.2 and 144.97 packet; Tokyo Disneyland on 2m repeater; Euro Disney on 440 repeater. Send SASE and QSL for collectable Disney Card.

OCT 12–13

MUSKOGEE, OK The Fort Smith ARC will operate KE5TC 1400–2130 Oct. 12th, and 1600–2130 Oct. 13th, in honor of the "USS Batfish" WWII Submarine. Operation will be on 14.250 and 7.240 phone. Send QSL and an SASE to *Royce Rainwater KE5TC, P.O. Box 236, Keota OK 74941 USA.*

OCT 12–14

GREAT LAKES, IL The Great Lakes ARC will operate WV7T from the U.S. Naval Training Center, in celebration of the U.S. Navy's 221st Birthday. Operation will be 0000Z Oct. 12th–2359Z Oct. 14th. You can find them on the 80–10m band CW, SSB and RTTY. Please include the provided contact number on your QSL. For a certificate, send QSL and SASE/IRCs to *Great Lakes ARC, 2072-A Langley St., Great Lakes IL 60088 USA.*

OCT 19

DUNCANVILLE, TX Station KC5SJX will be operated by the South West Dallas County ARC, in conjunction with the Duncanville Harvestfest, 1300Z–2300Z. Operation will be in the Novice 10m phone and CW subband. For a QSL card, send QSL and SASE to *SWDCARC, P.O. Box 381023, Duncanville TX 75116 USA.*

OCT 19–20

EDWARDS AIR FORCE BASE, CA The MARS Base Support Team will operate N6SFV on amateur frequencies, 1400 UTC Oct. 19th–0200 UTC Oct. 20th, in conjunction with the Edwards AFB Open House and Air Show. Freq.: 7.265, 14.265, 21.365 ± QRM, and 6m and 2m SSB. QSL with SASE to *WA6NKL, P.O. Box 874, Acton CA 93510.*

BROWARD COUNTY, FL The Hollywood ARC will operate WB4TON from the Broward County Historical Commission Pioneer Days, in celebration of the 100th Anniversary of the Florida East Coast Railway in Broward County. The station will operate 1300Z–2100Z each day in the 40m, 20m, 15m General phone and 28.400 MHz in the Novice/Tech band. For a certificate, SASE to *HARC, 720 N. 71st Ave., Hollywood FL 33024 USA.*

OCT 31–NOV 1

BREVARD, NC The Transylvania County ARC will operate station KE4ZIS from Transylvania County NC on Halloween. Hours of operation will be 1900Z Oct. 31st–0100Z Nov. 1st. Freq.: 7.237, 14.295, 21.365, 28.335 SSB, and 146.52 FM simplex. For a certificate, send a business-size or 9"x 12" SASE to *T.C.A.R.C., P.O. Box 643, Brevard NC 28712 USA.* Weather permitting, operation will be from the Devil's Courthouse on the Blue Ridge Pkwy.

QRP

Continued from page 63

I did one version of the Two-Fer that everyone just hated. I really don't know why—the circuit worked as it should—but that project was a fizzle.

If you've been following this column for the last 10 years you may have noticed a dearth of receivers. I'm no RF engineer, so most of the receivers I've designed sucked! I'm working on it, so perhaps you'll see a simple superhet receiver one of these days.

Antenna tuners have been a problem. I can't find a solid source of inexpensive parts for a tuner. You can get one ready-made by MFJ cheaper than I could build one. It's one of those projects still on the back burner.

To me, it seemed kinda silly to build an amplifier in a column about low power communications. But there again, who knows? Perhaps I'll come up with an amplifier that's simple to build and set up.

Most, if not all, of the PC boards used in this column can still be obtained from FAR Circuits (18N 640 Field Court, Dundee IL 60118). Write to them and ask for a product listing. An SASE will speed up your request.

The coming new century

Low power ham radio is enjoying steady interest. It's easy to just plunk down your plastic and walk home with a complete radio system. In one small box, you get built-in antenna tuners, DSP, and a zillion other goodies. In some cases, if the operator needs to have a microphone connector installed, he or she must find someone else to install it.

QRP means low power ham radio. It does not mean using decades-old circuits. In fact, you'll find plenty of microprocessors in our QRP gear. The QRP+ from Index Labs is a good example of what you'll come up against in the QRP field today.

During the next 10 years, we'll keep you informed as the latest and greatest equipment comes along. Right now, I'm busy trying to teach myself 68HC11 assembly programming. Who knows? In a year or so, you may see a home-brewed micro-based QRP rig presented in this column. In the meantime, let's just have fun!

What's All This QRP Stuff?

Home-brew a QRP rig.

Ken Gledhill AA7PE
19503 Via de Arboles
Queen Creek AZ 85242

It was shortly after midnight when I finally soldered the last connection to my home-brew multiband QRP rig. The project had consumed many of my evenings and weekends for most of the past year. The receiving portion of the project had been working for several weeks: now was the moment of truth—time to try the transmitter.

The oscilloscope showed that my voice was running 30 volts peak-to-peak across the 50-ohm dummy load. That figured to be just a bit over 2 watts of peak envelope power (PEP) on 10 meters. It was late, so I suspected that the higher bands would be shut down, and a few minutes of scanning up and down 10 meters confirmed my suspicion. So I telephoned and woke N7RSR, a nearby ham friend. I knew he'd understand—he's as crazy as I am about such things. We agreed to meet on 28.500 MHz. After a couple of short calls I received a sleepy response: "Your frequency is pretty close for an analog rig."

The next day was Saturday. There were a number of stations up and down the band, including one from the Fiji Islands. There was a big pileup of stateside stations trying to get through. I figured that it was a long shot with only 5 watts on SSB, but I called anyway. I missed him. He came back to a big station from California. I waited and tried again just as they signed off with each other. This time I heard "Go ahead AA7PE." I couldn't believe it! With only 5 watts, my SSB signals had reached Fiji with a respectable 5 by 5.

"With only 5 watts, my SSB signals had reached Fiji with a respectable 5 by 5."

Usually CW transmitters with output power of 5 watts or less are classified as QRP rigs. However, SSB voice transmissions may be up to 10 watts PEP and still be considered QRP. There are really no absolutes with these definitions, but these values seem to be widely accepted among QRP enthusiasts. These power levels are a maximum for QRP, and it's not uncommon to find QRP transmitters that operate at considerably lower power.

So why is 10 watts considered QRP for SSB rigs when the QRP limit for CW is only 5 watts? Consider first a CW transmitter. Assume that the key is up for approximately half of the time and down for the other half. Under these circumstances, a 5 watt CW transmitter will have an average output power of 2-1/2 watts. The average output of an SSB transmitter depends on your speech patterns, but the average output power of a 10 watt SSB transmitter is usually fairly close to the same 2-1/2 watt value.

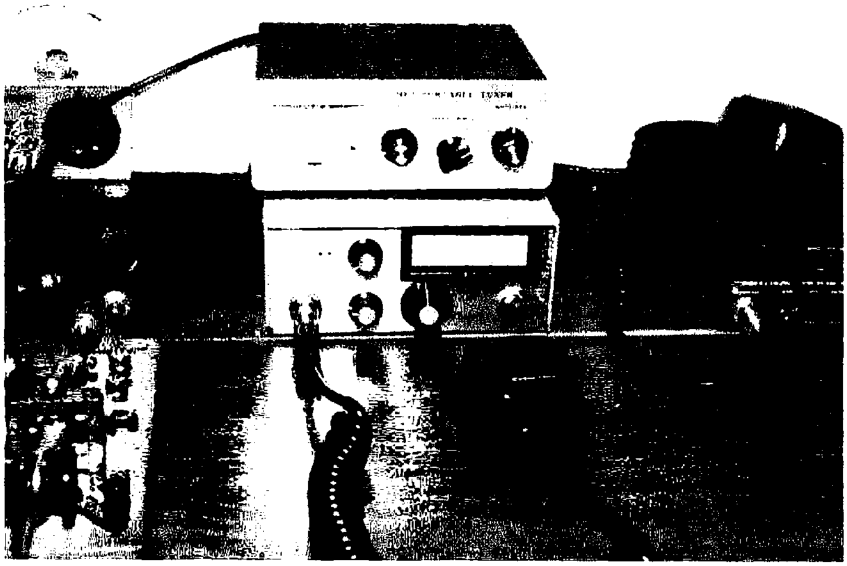

Photo A. The author's QRP station. In the center of the photo is a home-brew 5 watt SSB transceiver that operates on the 17 meter band.

Signals vs. noise

Although the power radiated from a 5 watt CW transmitter is comparable to that coming from a 10 watt SSB rig, the ability of the receiving operator to interpret the signal at the receiver is not the same. The difference in intelligibility is due to a couple of factors. The first is the signal-to-noise ratio (SNR), which is a measure of the degree to which a signal stands out above the background noise. If a signal is received with a high SNR, there is very little interfering background noise and the message is readily understood. Conversely, signals received with a low SNR are buried in noise and difficult to interpret.

There are a number of factors that affect the SNR of a received signal. One is the bandwidth of the receiver. Some

receivers use the same bandwidth for both SSB and CW signals so there will be little difference between the received signal-to-noise ratio of a CW signal and that of an equally strong SSB signal. However, if the receiver has a narrow filter, a considerable improvement in the CW signals results. For example, a 2100 hertz SSB filter allows five times as much noise power to pass through it as does a 400 hertz CW filter. With the lower noise power admitted into the receiver, the ratio of the signal power to the noise power is improved. Looking at the situation another way, a receiver using a narrow CW filter can distinguish a 5 watt code signal with the same degree of clarity as a 25 watt signal passing through a wider SSB filter. This feature underscores one of the key reasons that CW is the mode of preference when operating QRP.

CW has a second intelligibility advantage over SSB transmissions, even when received with a similar SNR. For a voice message to be properly understood, it must stand out above the background noise enough for the listener to distinguish the spoken syllables and link them into meaningful words. To distinguish among similar-sounding spoken letters such as P, B, E and D, a phonetic alphabet has been developed.

In contrast to spoken messages, CW doesn't require the listener to distinguish among subtle differences. The signal is either on or it's off; it's much easier for the human ear to copy the message in a noisy environment.

S-meters

Most receivers are designed so that each S-unit represents a fourfold difference in the received signal power. That means that the received power from a signal registering S8 on a particular receiver's S-meter is approximately four times that of one received with an S7 reading. Therefore, if the signal from a 100 watt transmitter registers S9 on a particular receiver's S-meter, by reducing the output power to 10 watts the S-meter reading would only drop to a little over S7.

One evening I was involved in a pleasant SSB contact on 17 meters with a ham located a few hundred miles away. When I mentioned I was only running 5 watts he was surprised by how well my signal was doing (S7) and asked me to check his signal for a test. His 100 watts tipped my meter up to S9 during audio peaks. When he reduced his transmitter power to 50 watts I could see no change in his S-meter reading. He then reduced power twice more, finally ending up at 10 watts. His signal was still a solid S7 on my meter.

ionospheric skip seems to occur more frequently. Noise and absorption are noticeably less on this band than on the lower frequency bands.

20 meters is a very popular band. It often works well for QRP, as it did for me when I connected with the Fiji station.

"Put your money and your time up in the air."

When operating QRP you'll meet all kinds. Shortly after making the Fiji contact I hooked up on 10 meters with a ham about 500 miles away. He said I was pushing his S-meter to a little over S9—but after I explained that my rig was only running at 2 watts, he revised my signal report to an S4. I often get better signal reports if I don't mention my power.

When the ionosphere is cooperating, QRP rigs work just fine. But when the sunspot numbers are low it is not uncommon to tune the entire 10 meter band without hearing a single station. In this condition not even a kilowatt will work.

Your antenna is critical

The better the antenna, the better your signal, since a good antenna improves both the received and transmitted signals. Put your money and time up in the air.

Operation on the lower frequencies is usually most effective when vertically polarized antennas are used. Higher frequency signals do better when horizontally polarized. A beam antenna can add as much as two S-units to your signal strength.

Which band is best?

If you're looking for reliable short-range QRP contacts, then 80 meters is a good choice. Clubs should find this band ideal for local on-the-air round-table discussions. Atmospheric noise can be a significant challenge on this band. The daytime range for an 80 meter QRP SSB rig is usually up to 25 miles. At night contacts can be made over longer distances, with contacts up to 120 miles not uncommon.

Long distance QRP contacts are more likely on 40 meters—especially in the evenings. This is my favorite CW band.

Voice is not allowed on 30 meters, so this is an excellent band for CW. Long-range propagation on 30 meters is similar to that on 40 meters except that

However, the popularity of this band often creates pileup conditions that favor the high-power rigs. Successful QRP on this band hinges on your skill and patience.

The higher HF bands of 17, 15, 12 and 10 meters are great for QRP. I've had many successful long-distance QRP contacts on these bands.

Clean signals win

Although there are subbands reserved for QRP operation, most reduced-power contacts are made with stations that are not operating QRP rigs. Indeed, many hams don't really enjoy trying to pull a weak signal out of the noise. However, you can increase your success by making sure your signal is clean, with no clicks or chirps. Listen to a recording of your signal so you can hear what your "fist" sounds like. On SSB, while audio compression provides a bit more average output power, I have found that my QRP signals seem to be more intelligible to the receiving operator when they are unprocessed.

The excitement of hearing your callsign breaking through the background noise as it returns from some distant point on the globe is hard to explain to the uninitiated. By learning to be an effective QRP operator you can beat the odds more often, enhancing your enjoyment in ham radio's most satisfying challenge.

Stress!

It's a concept with which we've all become too familiar, as we attempt to cope with it in our daily lives. Did you ever stop to consider, though, that your electronic equipment is also subject to stress? Just as you can stand only so much before you finally break down, your radio gear will also quit if the stress gets too high. In fact, many equipment failures are due to stress. This month, let's take a look at the types of electronic stress and how it affects various components.

Electronic parts and assemblies are adversely affected by three primary kinds of stress: mechanical, electrical and thermal.

Mechanical stress

Most mechanical stress occurs when sudden force is applied to the unit. In other words, if you drop it. Or, perhaps, a mobile radio could get broken after your car goes over a particularly violent bump. Maybe you carry your HT in your back pocket, and you forget and sit on it.

Dropping rigs usually results in serious damage. The parts most affected are the PC boards and anything made of glass, such as LCD panels. The point of impact will be hit especially hard, but other spots can get wrecked, too. In particular, the corners of PC boards frequently crack or break off. With simple, single-sided or double-sided boards, you can often fix them with wire jumpers. With multilayer boards, you're most likely out of luck. Fortunately, very little ham gear uses multilayer boards, but expect that to change as radios get smaller and smaller. The modern, 1.5-pound camcorder makes extensive use of boards up to six layers deep (!!), and future HTs undoubtedly will, too.

Board cracks often occur in the area of larger, heavier components, such as transformers, big electrolytic caps and power transistors, because their greater mass exerts more force on the board when the unit hits the ground. Sometimes the cracks will be quite obvious, while other times you may need a magnifying glass to see them. Now and then, the component will break the foil but not the board itself, making it even harder to find the trouble. Such breaks tend to look like cold solder joints, and almost always occur on large connections. I've never seen them happen on little transistors, but I've run into plenty of them on power transistors and transformers. When in doubt, resolder.

Double-sided and multilayer boards use what are called "plated through" holes. Essentially, the walls of the holes have copper linings. This technique makes for solid, trustworthy connections between layers, but it has a few drawbacks. The best-known one is that plated through holes make it very difficult to remove parts. Because solder sticks to the plating, you can count on the holes' being filled with solder, and you have to get them really hot in order to melt it all at one time. If you're not successful at that, you'll damage the board, either by lifting and tearing the plating on one side (usually the component side, which is farthest from the iron), or by pulling the plating right out of the hole! I've seen that happen more than once. Although it can be disastrous with multilayer boards, double-sided boards usually survive this problem; you just have to be extra careful to solder the component lead on both sides of the board.

> **"When in doubt, resolder."**

The result of sitting on an HT is pretty much the same: The board and display get cracked, often so badly you can't fix the radio. This time, though, the larger components aren't the issue, as the force has not been transmitted to the board through them. Cracks may be distributed fairly randomly over the PC board, which is a big part of the reason the radio may be ruined. At least with cracks resulting from drops, there's usually a pattern.

Vibration-induced damage is somewhat different. Although the board can, indeed, be cracked, it often isn't. More likely, the solder joints themselves are affected, and you can easily resolder them (if you can find them!).

Mechanical stress affects more than PC boards, though. Switches, controls and jacks are particularly subject to it. Pots get scratchy and intermittent from being constantly turned back and forth, and switches may start making unreliable connections for the same reason. Sometimes contact cleaner helps, sometimes it doesn't.

Electrical stress

Within the category of electrical stress, there are two kinds: over-voltage and over-power. Over-voltage stress induces failure in all kinds of parts by punching microscopic holes in them! Electrons being the energetic little critters they are, they'll try and force their way through any kind of barrier. Raise the voltage, or electromotive force (EMF), of those electrons enough and they can go right through the substrates and molecule-thin barriers designed to keep them where they belong. The result is a short circuit inside a part.

Prime candidates for over-voltage stress failure are electrolytic capacitors, transistors, FETs, CMOS parts, and integrated circuits in general. But what causes the over-voltage condition in the first place?

Voltage regulator failures can cause the supply to put too much voltage into the wrong part of the radio. This happens more often than you might think, particularly when a secondary 5-volt regulator shorts out, sending the main 12-volt supply to a bunch of TTL gates or a microprocessor. *Poof* go the parts. If you change them without checking that regulator, the new parts suffer the same fate almost as fast as you apply power.

Depending on where you live, static electricity can be a serious problem. Northern winters can get extremely dry, and static can build up without your even realizing it. You touch your radio, and you feel ... nothing. The radio, though, receives a huge jolt and stops working. Of course, if the static charge is big enough, you'll feel it, but it sometimes takes much less voltage discharge than you can feel to do significant damage to electronic equipment. That's why it really pays to touch something grounded before handling your gear in winter.

Thunderstorms can have the same effect. I've seen computers fail to boot up the day after a storm, even though no obvious lightning damage occurred. Sometimes the machines will start working again, without intervention. Apparently, a static charge has built up somewhere, and it eventually discharges. Of course, sometimes there is actual damage, too.

Over-power stress is just what it sounds like: Too much power is passed through a component, heating it up and blowing it. In a sense, it's a kind of thermal stress, the difference being that the heating is internal, rather than from an external heat source.

The usual cause of over-power stress is a shorted component pulling too much current through another one. I call this "over-power" rather than "over-current" because current doesn't tell the whole story; it's the amount of current at a particular voltage that does the damage. So, over-power stress is best thought of in watts, not amps. That's why resistors, for example, are rated in watts. A 1/2-watt resistor could easily stand 5 volts at 50 mA (.05 amps), but 10 volts at the same current would put it at its absolute limit, and you could expect it to fail in a short period of time.

Another cause of overcurrent failure is bad design. We like to think our equipment is well-designed and will last a long time if nothing unusual occurs. Typically, that's true, but not always. Sometimes what looks right on paper just doesn't cut it in the real world. It's not unusual for a specific model to have a recurrent

problem, due to the design's not being thoroughly tested. I remember one VCR model, back in my service tech days, that blew the same transistor over and over again. Every time one would come in, we'd just go right to the same part and replace it. It worked every time, because it was always the same problem! When manufacturers figure out they've got a problem, they usually try to correct it through an engineering change order, or ECO, that changes parts or procedures. That's what service bulletins are for, and many pieces of gear have them. Some have whole books of them!

of RF power, you're going to have to dissipate anywhere from 20 to 70 watts or so of heat, too.

Heat-producing parts, such as power transistors and RF final amplifier modules, are heatsinked to a big piece of metal, which is often the chassis of the radio itself. If the rig is properly designed, most of the heat will flow into the metal and away from the semiconductor producing it. As long as the whole set stays under a certain temperature, everything's fine, as no part gets hot enough to sustain damage. But if the fan fails, or you mount the set in direct sunlight, watch out for trouble. Some designs

"It worked every time, because it was always the same problem!"

Thermal stress

Thermal stress is overheating from some external source. The source can be anything from a hot component a millimeter away, to the sun in a hot car. Any way you slice it, heat is the enemy of electronics—period. Of course, some parts have to get hot in normal operation. Unlike in the tube days, though, the heat is pretty much never a desirable or necessary condition. Still, nothing's one hundred percent efficient, and some heat will always be generated. If you try and make 50 watts

aren't so well done, and the radios tend to overheat anyway. Tiny HTs get ridiculously hot when you transmit for long periods at 5 watts output or more. If the thing is too hot to hold, just imagine what's going on inside! The heat may not cause immediate destruction of the rig, but its lifetime is sure to be seriously reduced.

Now that we've covered the basic stress guidelines, we'll take a look at individual components and examine the kinds of stress to which they're susceptible ... next time. Until then, 73 de KB1UM.

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92837

Dirty Tricks = Valuable Training

When April WA6OPS and I discovered two miles of power line maintenance road running through the hills behind new houses in east Yorba Linda, we knew our search was over. We were checking out the area because it was our turn to be hiders for the monthly Fullerton Radio Club (FRC) hidden transmitter hunt, along with Tom and David Curlee WB6UZZ and KE6IPY. We call these events "T-hunts" here in southern California; in some other places they are called "foxhunts."

The site we chose was ten miles due east of the hilltop where the hunters would gather to start. Over the years, FRC T-hunters have gotten so good at radio direction finding (RDF) that it could be a short hunt, unless we added a few twists.

First we put up a 4-element yagi, coax, transmitter box and battery on the roadside fence. It would have been a functioning hidden T, except there was no fuse in the 12-volt power cord. Next to this decoy was a sheet for the hunters to sign in and record their odometer readings.

The real signal on 146.565 MHz at 8 PM on hunt night came from a quarter-watt handie-talkie in a surplus military ammunition can that we concealed in the brush about 60 feet away from the fake T. In accordance with the hunt rules, any passenger car could be driven to the site by going a few miles east of it into a new housing development, then back west on the wilderness road. We parked our car on a street three quarters of a mile west of the site, expecting to see hunters trying to get there by that route.

Time is not a factor on the FRC hunt. The team with lowest mileage traveled wins. Nevertheless, all of the seven hunting teams were close after a few minutes. Three followed the signal to our observation post and tried going out a dirt road there, only to encounter a locked gate a half mile west of the T. Others parked at another locked gate south of the site and hiked several hundred feet north up a steep hill. Only one team (WB6DCC, WB6DCB, KD6HWD, and KD6MCM) drove to it via the power line road, which gave them high mileage at that point.

Every team stopped upon spotting the decoy, signed in on the sheet, and called us on the frequency posted there. We told them that if they believed that they had found transmitter #1, they should next try to find a second transmitter we had hidden on a different frequency. The FRC hunt normally has only one transmitter to find, but all teams had signed in within an hour and forty-five minutes, so it wasn't hard to convince them to do some more T-hunting.

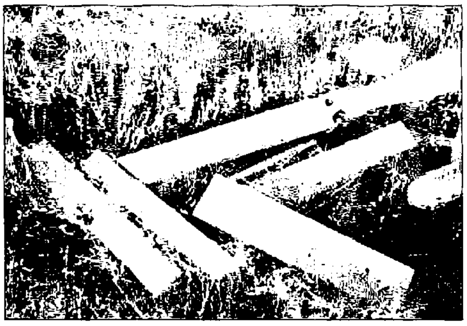

Photo A. The "Stud T" looked just like all the other two-by-fours in the pile. In fact, it had been in precisely that same spot a week earlier when I picked it up.

The Stud T

Transmitter #2 was only 1.6 miles away atop a hill, but it was no ordinary hidden T. In a pile of scrap lengths of two-by-four lumber, one piece was different (**Photo A**). A microtransmitter, batteries and dipole wires were actually inside the two-by-four. The wood shop magic was courtesy of WB6UZZ. He sliced it like a bagel and hollowed out the insides. Then I fastened the electronics in place with hot glue (**Photo B**).

Instead of a tone generator, this T had a very sensitive mike. From our parking spot, we could easily hear the hunters approach it. We were not secretly "bugging" them, because they realized what was happening within 50 feet of the T when their receivers started squealing with audio feedback. They were able to zero in by turning down their receiver audio as they approached and then banging on the two-by-fours until they found the right one. Five teams grabbed it more or less simultaneously and called us on the frequency on a little label next to the tiny mike holes in the board.

At that point, we announced that no team had as yet tracked down the *real* transmitter that they had started out to find. In a stampede, almost all the teams headed off to try again. Apparently, they all drove back to the points from which they had started walking the first time. The WB6DCC team, having discovered the eastern route earlier, added much less mileage than the others. As a result, they ended up as winners. Most teams pounced on the real T #1 and checked in within 15 minutes, so there was still plenty of time left for food, talk, and a close examination of the "Stud T" at a nearby restaurant.

Most T-hunters like intrigue and cunning, so they were good sports about the deception. Don Lewis KF6GQ wrote on E-mail the day after, "We knew that you had pulled something tricky, but when I tried to sniff it out with the rubber duck, all I got was a stronger signal on the other side of the fence. When we came back (the third time for us), I took the 3-element beam and DFed it down myself, instead of watching the others and checking in at the decoy as I'd done the first time. Never, never, never trust what you see others do! It was a very, very good hunt because it was both fun and frustrating."

Tom and I certainly were not the first to camouflage a hidden T or even to encase it in wood. The Internet RDF mailing list has had transmitter-in-a-log stories from Seattle, Washington, and Melbourne, Australia, in the past year. There is no limit to clever disguises, so experienced hunters have learned to always carry along good on-foot RDF gear.

Decoys are unusual also, but they are not new to our hunts. Ken Diekman WA6JQN was probably the first to use them here fifteen years ago. They serve a valuable purpose because they remind hunters to pay attention to their equipment. T-hunting is an RDF exercise, not an eye test. If hams are going to convince the FCC that we are good enough at it to provide evidence for jammer prosecution, we had better always find the real transmitting turkey and never falsely accuse an innocent ham with a big beam next door.

Helping hams in the heartland

The fun and camaraderie of hidden transmitter hunting pays off doubly when the RDF skills it develops are used for public service. Examples of this can be found in Omaha, Nebraska. According to television engineer John Gebuhr WBØCMC, the Ak-Sar-Ben Amateur Radio Club has encouraged T-hunting for many years.

"On our monthly foxhunts, we just go out and have a good time," John says. "Usually they are held on the Sunday afternoon following the monthly club meeting, but we have also had them in the evening hours. Sometimes we have a picnic afterwards. The fox uses the radio club's call and results are published in the club paper, but they are kind of a loose informal event.

"Most hiders use the club's fox transmitter," WBØCMC continues. "It's in a weatherproof container, battery powered, and will run for six hours at one or 10 watts. It comes on for one minute and then shuts up for three. We start the hunts from the University of Nebraska parking lot. The fox has been in dumpsters, up in trees—you name it. We've done

a few mileage hunts, but usually the first team to locate it wins and gets to hide the fox the next month.

"I drive a T-top and use a 3-element beam on a wood pole that sticks up into the air. We had one guy some years ago who had a Doppler and was pretty good with it, but most of the guys now are using handie-talkies and beams. In fact, some of them just use handie-talkies and body shielding. The boundary is pretty broad, including most of Douglas County and over to Pottawattamie County in Iowa. Sometimes the hider will put the fox along the Missouri riverbank, and the big trick becomes trying to figure out which side of the river the thing is on."

Nebraska's ARRL Section Manager Bill McCollum KEØXQ is another regular hunter. He and WBØCMC have used their T-hunting skills several times over the years to track repeater jammers and bootleggers. "Some of the bootleggers that we've tracked down eventually turned into good hams," Bill says.

"We keep on top of it," John adds. "When turkeys pop up, we find them, they know they have been identified and we just don't have the problem again. For example, about a year and a half ago in the dead of winter, somebody would come on at 2 AM every morning and get on the autopatch, dial up numbers and never give a callsign. Bill and I nailed him and the problem went away."

Of course, not all interference is deliberate. Sometimes it's the result of a technical problem. According to John, "One day we started hearing military voices over one of our repeaters. I quickly determined that the signal on our input was coming from Offutt Air Force Base and called Communications out there. I told them, 'Your generals are being heard all over Omaha.' In an hour the interference was gone."

The Amateur Auxiliary to the FCC has been a success story in eastern Nebraska. John says, "Before the FCC's monitoring station at Grand Island closed, I would sometimes get a call from Rebecca out there asking the hams to check something out. We found all kinds of technical problems, spurious transmitters and such. Usually when we find somebody with a bad transmitter, it's fixed within a week. There was only one such incident that we really had problems resolving, and that was a major industrial company and its RF heating equipment at 13 MHz. The transmitter had a free-running oscillator with no frequency control except one tuned circuit.

"The little antenna they were using to couple 10 kilowatts into the work happened to be 19 inches long. So guess where the worst harmonics were! They were getting into every repeater in the Omaha area and even into Fremont, 32 miles away. They were getting into our 222 and 440 MHz frequencies, too, but not as bad. Because they had a harmonic in the aircraft band, we were able to get pressure from the government to get it fixed."

"'Your generals are being heard all over Omaha.'"

RDF services by Omaha hams are not limited to Amateur Radio bands. They have helped other local agencies as well. "Seven or so years ago, I got a call from Douglas County Civil Defense (CD), which uses a frequency near 155 MHz," says WBØCMC. "That agency is responsible for setting off sirens for tornado warnings and such. Somebody had been giving false calls on the CD frequency. It had gone on for two nights and they figured there was a good chance he'd be out that night, too.

"We got five teams out. Sure enough, he came on and we tracked him to the Douglas County Annex building. It turned out to be a security guard who had picked up a CD handie-talkie from the charger. I called the CD chief and they sent the Sheriff out there. It didn't happen again."

Always gets his man

"John is really good at RDF," says KEØXQ. "There hasn't been anything yet that he hasn't been able to find." The most recent and most serious mission came on April 3, 1996. As Bill and John were talking on the phone, Bill noticed that Omaha Police Department radio calls were coming through the 146.94 repeater. "At first we thought somebody had a stuck 2 meter radio with the mike on top of a scanner," Bill says. "Later we found out that police cruiser radios were picking up hams talking on their channel at the same time."

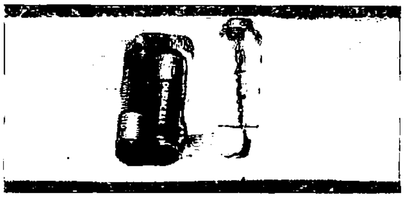

Photo B. WB6UZZ used a router to make room for the hidden T parts. The two-meter transmitter is manufactured by Agrelo Engineering, 1145 Catalyn Street, Schenectady NY 12303 (518) 381-1057.

The two T-hunters drove around Omaha for about a half hour without hearing the police on the 2 meter repeater input. Then, on a hilltop west of Boys Town, John began to pick up a faint signal. He decided to go to Elkhorn, about six miles northwest of the city, where there is an Air Force antenna farm. It wasn't there, but the signal was about 20 dB stronger and still to the northwest. "I think it's in Fremont," John told Bill.

By this time Bill was in Bellevue, on the other side of Omaha. John continued westward. "Trying to drive and hold a three-element beam in a 60 mile-an-hour headwind doesn't lend itself well to precision RDF, but I could tell that the bearing continued to point right toward Fremont," he says. "I was in kind of strange territory, so I decided to get a local ham to go with me. I called Mac McCabe WBØIBV in Fremont. He said he would love to help. I also called the Dodge County Sheriff's office to see if they had a deputy to go along for safety's sake. These days, one never knows what he may run into when knocking on doors.

"The deputy got there before Mac and pulled up alongside my car. He looked at the car, looked at the beam sticking out of the roof and then started to chuckle. I explained who I was and what was going on. Mac showed up and off we went."

A few minutes later, they pulled into a parking lot where the signals were super-strong. They asked the workers there if anyone had left a 2 meter radio on. One went over to his car, got in, and the interference stopped abruptly.

To link ham and police frequencies together, the perpetrator had to set up his dual-band radio in the repeat mode with the right frequencies, offsets and subaudible tones on both UHF and VHF. "It became obvious that this was deliberate," says WBØCMC. "Most people who do something like this inadvertently are apologetic when confronted. Not so here. This fellow was very tight-lipped, wouldn't look anybody in the eye, and gave the impression that he hadn't thought he'd get caught. We identified him, turned our information over to the authorities and haven't had a recurrence.

"We made some real good friends with the Omaha 911 people as a result of this. The following Saturday, several of us met with the 911 Chief of Communications and the Assistant Douglas County Civil Defense Director. We got lots of thanks and an opportunity to give them a briefing on the Amateur Auxiliary program."

Let's go browsing

The new "Homing In" site on the World Wide Web is a good way to learn how to get your club started in hidden transmitter hunting. Besides answers to the most frequently asked questions about RDF, you will find Web links and E-mail contacts to hunt groups in cities and towns all across the country. Point your browser to http://members.aol.com/homingin/ to check it out and then let me know about T-hunts in your town. You can send E-mail to Homingin@aol.com or snail-mail to the address at the beginning of this column. 73

Never say die

Continued from page 61

most of these things, and that the results can be all kinds of lingering illnesses.

On the bright side, the book explains how simple it is to find out what you are allergic to so you can avoid that allergen. It's merely a matter of counting your pulse rate after eating or exposure to different substances. With foods, you can isolate which are treated as hostile by your body just by checking your pulse several times after eating. Well, get the book.

Yes, I'm selling my list of recommended books for $5. If I were selling the books, it would be a free catalog. But the list is the result of a lifetime of reading and the revenue from it goes for photocopying, folding, assembling, addressing and mailing it, plus money to buy more books. So far this month I've bought 17 more books, most of them on the recommendation of readers as books *I* really ought to read.

Getting back to allergies, a recent TV documentary introduced me to Dr. Doris Rapp, who explained that many of the behavior problems kids have stem from allergies. Like hyperactivity, attention deficit disorder, dyslexia, poor grades, fatigue, personality changes, poor concentration, depression, and so on. I probably should put her book, *The Impossible Child*, 161p, $11, ISBN 0-9616318-1-3, on my list, particularly for parents—though people of all ages can have these same reactions to allergens.

My hay fever hit not long after childhood immunization shots. I had the usual scratch tests, where I was found allergic to dogs and cats, a few foods such as cheese, trees, grasses, and most pollens. Dr. Coca's book explains that the scratch test misses many allergens and that the pulse test is much more reliable. It's also one heck of a lot easier and cheaper. Which probably explains why few doctors are aware of the test, even though it's been around for over 40 years.

Apropos that, I've already mentioned the inexpensive cure for epilepsy which one determined doctor has kept going at Johns Hopkins Hospital, but which otherwise would have been lost. I keep finding out about more and more buried medical treasures like these. But then the medical industry is in the hands of a few pharmaceutical companies, the music industry is totally under control of seven international music companies, and so it goes, with us paying the tab while we sit here watching ball games and drinking beer.

"An AMA report showed that doctors live an average of 58 years, while the rest of us manage to live an average of 75 years."

Those Pesky UFOs

I see where the Pentagon has managed to produce a five-pound book whitewashing the "Roswell incident" of almost 50 years ago. News flash: It *still* was a weather balloon. Sure. But if you've read anything about it or seen any of the several exposé TV shows on the subject you'll know the Pentagon is again handing out baloney.

Oh, I agree there are a lot of crackpots involved with UFOs. But then, there are a lot of crackpots involved with anything arguable. In general, crackpots are people who have not bothered to do their homework, but have not let that interfere with them having strongly held opinions. Or, on a more practical level, a crackpot is someone who strongly disagrees with you on some subject, whether you have any real basis for your beliefs or not.

Is Strieber, who wrote *Communion*, and more recently, *Breakthrough*, a crackpot? His story of his many contacts with the alien visitors is fascinating and makes sense. Are the millions of people who have reported seeing UFOs all crackpots? How about the thousands of contactees with stories similar to Strieber's?

A reader says he's been able to photograph UFOs reliably by using a building or something to block out the sun so he could take pictures of the sun's corona. He says the UFOs are coming and going from the direction of the sun and thus aren't easily seen. He described 15 different types of UFOs he spotted in just a two-day vigil.

So if there are aliens visiting us, why aren't they open about saying hello? I suspect it's because they are on scientific expeditions, not military, and they've been doing this for a long time—possibly for thousands of years. I don't think you'll disagree with me that we have not progressed socially to the point that it's safe to mess with us. The hints of their technology tell us that our visitors are far ahead of us, so what possible benefit would it be for them to do more than unobtrusively observe us? If we could go back and visit Earth the way it was a million years ago, would we land and say, "Take me to your leader?"

Well, you're interested in communication. Our visitors aren't using radio, which makes sense to me, so how are they communicating?

I Haven't Got Time

A friend called. When he mentioned having been sick, I naturally suggested he get some books on health and take some responsibility for his body. He said he didn't have any time to read. I don't either, but knowing how important it is to my goals in life (like living as long as I can so I can accomplish my other goals), I *make* the time.

Books, such as those that are on my $5 "books you're crazy if you don't read" list, can help extend your life on to 100 or so. For me that's another 25 years to learn and teach.

Like most other people, I was inculcated by our school system to believed that school and college were the main ways to learn. Experience has taught me the long, hard, expensive way, that you can learn more with a good book in a few hours than you can in college in a few weeks. You don't have to go to a class to learn about radio and electronics, all you need to do is read some books and you'll soon know more than most of the teachers. We're so brainwashed that few people ever even think to question the value of college. My folks never did. Heck, my father came along at WW1 time and missed college. He went to New York Military Academy and from there into the Army as an officer. That got him into aviation with the Army Air Corps. But he always felt the lack of a college degree, even when he was busy starting new airlines. He started three of 'em, including the first trans-Atlantic airline.

"Reading books, such as those that are on my 'books you're crazy if you don't read' list, can help extend your life on to 100 or so."

In just a few weeks of reading you can become an expert on almost any aspect of electronics. But, like exercise to build strength, you do have to tackle the job conscientiously.

I keep bringing up health because you're not going to be able to do much if you're heading for a heart attack or cancer, like over half of your friends. That road is for the ignorant. Ditto all of the chronic illnesses, including diabetes, arthritis, and so on.

You can give me a hand with this. Every time you buy an electronics or radio book, please read it carefully and then send me a book report for possible publication in *73*. If it's a bad book, the review will help spur the publishers to do better. If it's a good review, I want to know so I can read the book, and so do the other *73* readers. It'll also help sell a bunch of books, and that too will encourage the publishers to do better and stop publishing junk and textbook-type boring stuff.

Amateur radio can once again be worth its salt if I can get you to take advantage of the many opportunities for pioneering. But to do that you have to start by learning all you can. Will it be a ham who develops and pioneers digital communications? We did that with FM, NFM, slow-scan, and sideband. But so far we're sadly behind when it comes to digital voice systems using data compacting algorithms.

I'm reading every club newsletter I get, looking for any signs of hams doing anything more than having fun with a hobby. I see no signs. That's why I get so nervous and critical when I read about the ARRL getting pushy with the FCC over one thing after the other. It just doesn't pay to give the boss a hotfoot.

Special Forecast

Cycle 21 bottomed out in December 1986, and it now looks like Cycle 22 will bottom out around December 1996 ... just 10 years later. Yes, I had predicted an earlier (May) sunspot minimum, but Old Sol is hanging in there with depressingly low flux values (around 70) which refuse to climb out of the basement. The pundits are now saying that the reported spot of the new cycle was just a fluke ... a Chimera ... an apparition. Frankly, I don't think so. It was real enough and was, in fact, the harbinger of Cycle 23, I believe.

As propagation goes, October could be an *awful* month; either wonderfully awful or awfully wonderful. I predict that the days surrounding the 10th and the 23rd will show some remarkable and extensive geophysical disturbances: possible hurricanes, volcanic eruptions, and earthquakes.

27 F	28 F-P	29 F-P	30 P	31 P		

Heaven knows, there might even be an active ionosphere! It sure is about time! Whatever happens, it won't be docile and calm. Maybe there will be a stock market crash ... it's the right month.

When solar flux is very low, as it has been for months, an ionosphere storm could be a boon and kick the flux up where we'd like to see it ... at least for a few days. When flux is high, as at the peak of a cycle, an ionosphere storm often results in too high a flux value and poor conditions. Therefore, I'll suggest that the days marked P or VP on the chart could, in fact, be very *good* days for propagation, so keep those receivers tuned to the higher HF bands and hope. Also, keep your emergency gear ready for anything!

10-12 meters

Generally Poor, except for occasional transequatorial propagation with F2 openings on the best days—most likely South and Central America.

15-17 meters

DX to Africa and Latin America on the Good days possible, with short-skip out to about 1,000 miles or so in the U.S.

20 meters

Your best band for DX openings around the world from dawn to dark, and openings to the Southern Hemisphere after dark in evening hours. You can expect excellent short-skip during the daytime to 2,500 miles or so.

30-40 meters

These bands ought to be open for DX from just before sunset to just after sunrise. Signals from the east should peak until midnight, and after midnight to other areas. Daylight short-skip of about 500 miles will be possible, and night-time short-skip to 1,500 miles or more will be available.

80 meters

Occasional DX to various areas of the world should be possible between sunset and sunrise when QRN levels permit on Good (G) days (see calendar), and also short-skip during hours of darkness to 1,500 miles or more.

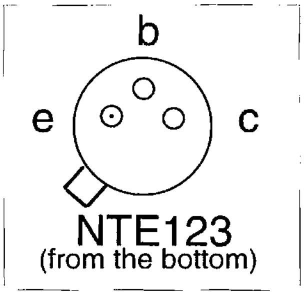
160 meters

Following the usual summertime slump, this band ought to begin to come alive again during the hours of darkness when QRN permits. Try the days marked (G) on the calendar for best results. DX toward the east until midnight, and to other areas afterwards until dawn. Short-skip to 1,500 miles will prevail when the band is quiet. W1XU. 73

UPDATES

You say you're having trouble with that preamp...

Before you spend another weekend trying to find out what went wrong with that preamp circuit that you constructed according to Roland Burgan KB8XI's article (August *73*), take a look at the pinout diagram that was inadvertently omitted from the schematic:



BEAR-ly There

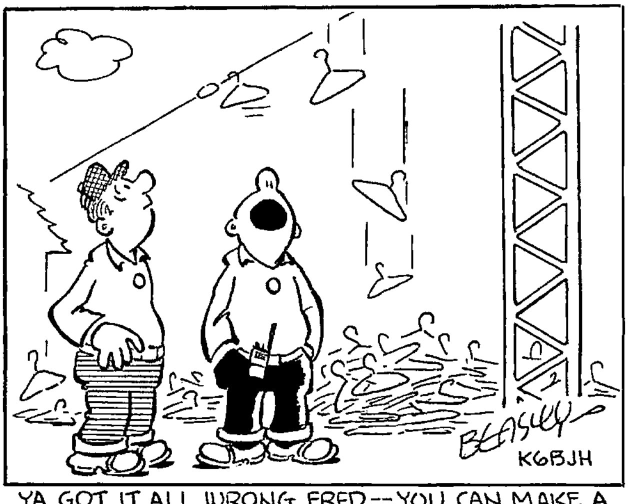
The June table of contents erroneously credited Pete Kemp KZ1Z's article "The BEARS Hunt the Fox" to Mike Bryce WB8VGE.

The Book List by Wayne Green. This is a list of 83 books that I say you are absolutely crazy if you don't read. And none of this "I don't have time to read" crapola. These books are the best books I've found in a whole bunch of fields. Many were recommended by readers as being top notch. It's time to become educated on health matters, our school system, our corrupt government, history, science, communicating with plants and animals, child development, the occult, and so on. Order **BL** $5 from Radio Bookshop.

It could happen to anybody...

In KB4ZCG's August article, "Simple Crystal Activity Tester," the R5 Øk ohm potentiometer in the parts list should read, **"R5 10k ohm potentiometer**."

NASA Mooned America by René. The proposition that the Apollo flights were all faked and NASA never got anyone to the moon is patently ridiculous. I'm still waiting to hear from anyone who has read this book and still believes the moon landings weren't the biggest hoax in history. René has done his homework thoroughly and cites 30 darned good reasons why he thinks we've all been lied to. 176p, 8½ x 11. Order **NA** $25 from Radio Bookshop.



YA GOT IT ALL WRONG, FRED--YOU CAN MAKE A 2 METER GROUND PLANE OUT OF WIRE COAT HANGERS, BUT NOT A 20 METER BEAM!

"R2... see if you can lock down that stabilizer."

In Frank Brumbaugh's "Automatic Voltage Controller" August *73*, look at the first line of the third column of page 46. The R5 that's there should be an R2.

The schematic on page 46 was missing the visual for C1. Here it is:

Never say die

Wayne Green W2NSD/1

Tampa: November 23rd

Yep, controversial Wayne Green speaketh! Come see what all the fuss is about. From noon until 2 p.m. at the Tampa Hamfest I'll be talking a blue streak and answering questions. On anything, so come armed. Yes, I'll talk about the possible futures for the hobby. Yes, I'll talk about religious issues such as CW. Yes, I'll talk about the hobby going to hell in a handbasket. Yes, I'll talk about the adventures amateur radio affords, and the excitement that pioneering new modes provides. Yes, I'll explain the secret for making all the money you want. Yes, I'll talk about how you can add at least 20-30 years to your life, if you're interested. These are exciting times, with cold fusion emerging as a new power source, with new discoveries about water, magnetism, health maintenance and repair, the mind and its repair, aliens, UFOs and other ridiculous stuff getting more real as you look into them.

Yes, I'll explain about some of the exciting books you can read to get your mind working again. Did NASA really fake the moon landings or has Wayne been conned by a clever new book? Have there really been highly advanced past civilizations? Do you have any understanding of how digital radio and television are going to change things? And how you may be able to benefit in a big way from these changes? There are billions to be made in these emerging technologies. Are you just going to passively watch it all happen, or will you get in there and help?

Bill Gates was there first with microcomputer software. Steve Jobs was there first with a single-board computer. They've done fairly well as a result. They saw opportunities and actually did something about them. Motivation. Determination. Perseverance. Never Say Die! Okay?

Hey, don't forget to have lunch early so I won't have to listen to your stomachs growling. Besides, that'll help me put you to sleep.

An Engineer Shortage?

Between an article in the *L.A. Times* and a recent PBS show, my contention that there is a desperate need for engineers has been confirmed. The *Times* article went into detail on the lengths some companies are having to go in their search for engineers. Like the California company that heard about an engineering department in Florida being downsized. They hired the engineers, setting up an office for them in Boca Raton so they wouldn't have to relocate. They then set up a communications system so they could be in close touch with the home office.

Well, we know that more and more software firms are farming out their work on contract to companies in India and Pakistan.

More and more Silicon Valley firms are hiring Chinese. Indeed, some have whole Chinese departments, where many meetings are conducted in Chinese. That makes sense since Asians, on the average, have about a 10-point IQ advantage (yes, they're smarter than us), plus they have an incredibly strong work ethic, something we've managed to virtually eliminate in American youngsters. And the US, compared to life in China, is a golden land of opportunity where hard work and skills pay off.

My proposal is to use amateur radio as a way to interest our kids in electronics so we'll have more American engineers, technicians and scientists in the next century. Alas, few kids today even know amateur radio exists. Our ham clubs, with few exceptions, are making little effort to generate more hams. Does your club get announcements of meetings and other activities listed in the local papers? Has your club made an effort to sponsor radio clubs in local schools? Has your club donated ham magazine subscriptions to local school libraries?

When I got interested in amateur radio the first place I went to was the school library. There I found a really great magazine, *Radio*. It got me fired up to start building ham equipment.

When I give talks to kids in the 5th and 6th grades they get all excited about our hobby. They know about CB, but that's old stuff now. Few have ever even heard about what we're doing. How long are you going to keep ignoring our (your) kids?

Heck, if they start automating our fast food restaurants a whole generation of kids will be unemployed. Hmm, let's see, now if we combined the old Automat system with a microwave for each food slot, customers could get hot sandwiches and stuff without any counter help. And the sandwiches could be precooked and assembled in factories by machines ...

Tech Update

The AIDS cure I described in my February editorial hasn't hit *Time* yet, but it is finally getting published in some medical journals, so the word is starting to get around.

I sent letters to my two senators and representatives in Washington, asking if they were interested in the AIDS cure. One answered, saying I should get in touch with the FDA if I had a problem. So I wrote to the head of the FDA and to the Health cabinet member. You guessed it, after six months, no answer. I also wrote to the editors of *Time, Newsweek, US News, Forbes, Fortune*, and a few other magazines. No answer from any of them.

Is it that no one of importance reads their mail anymore? I read mine, but then I don't count as a person of importance, except in my own mind.

I see that TNT is going to broadcast a film on Amelia Earhart. Well, they haven't contacted me, and as far as I know, I'm one of the few people alive who knows the inside story of her last trip. Frankly, I'm disappointed in you. I've written about this and you haven't passed the word. So I watched the recent TV program about Amelia blunder around, and ditto the author of the recent Earhart book. Tsk. Hey, she was a spy for the Navy, and I knew it *before* she made her trip, as I've explained.

I've been hoping to get some people in Congress interested in the cold fusion developments. I've had every bit as much success in getting answers on that subject. Things have been moving fast in the cold fusion department. The University of Siena, Italy, demonstrated a nickel-hydrogen system which generated lots of power and kept on doing it for weeks after all input was removed. It didn't stop by itself, they had to stop it. This is particularly interesting in that the reaction has been at relatively high temperatures (around 500°F), so it's a more efficient system. The estimates I've seen are on the order of 300 kilowatts from three grams of nickel. The university has not been forthcoming on their system for initiating the reaction, but from the pictures I've seen it doesn't look very complicated. This is obviously not a chemical reaction.

Cold fusion presents a wonderful opportunity for experimenters. First, it doesn't cost a bundle to experiment in the field. Second, it doesn't take a Ph.D. in chemistry or physics, or anything else, for that matter. This is a whole new field and there are few experts yet. You could be one, if you wanted. Third, all of the research in this field so far has been empirical, which means everyone involved is trying this and that, and seeing what works and what doesn't.

Pons and Fleischmann got started with this because they'd run across an anomaly that

Continued on page 9

LETTERS

From the Ham Shack

Elmer Sinclair KD4JUH. This was prompted by the reading of K9KPM's piece on the May "Ham to Ham" page. Since deciding late in life to get a ham ticket, I have had a fruitless though amusing time looking for the origin of the term "PEP." In explaining it, all references I've found in the amateur radio literature, as well as the answers I've received by raising the question, have reverted to the classical explanation of power using rms values of voltage and current. Some explanations confuse me by carelessly using terms such as "average" when "effective" is meant. The average value of a sinusoidal current is zero; the effective (rms) value is that which will produce the same heating effect in a resistor in the same given time as a DC current of the same value. By deduction, the same is true of a sinusoidal voltage, because V=iR. But i= Q/t, which is a certain charge moving past a given point in a certain time "t"; the standard value of "t" is one second. Furthermore, since power is a function of current, it also has a time component, namely the same one as "i." So what is the meaning of "peak" when used in conjunction with power, as in "PEP"? If it is an event having a time span of less than one second, what is the unit for PEP? If it can be defined with more traditional terms, why don't we?

Troublemaker ... Wayne.

Stephen Early NØSHT. The FCC has been lobbied heavily by a small group of hams who advocate the perpetuation of the Morse code requirements for operators on frequencies below 30 MHz (RR2735). The same group appears to also be upset with the no-code licenses. But without the no-coders the hobby was slowly dying. These new hams are not organized, therefore they have no voice. If the old-timers think the code is so critical, we should have proficiency tests for their license renewal. How about polling the newcomers on the value of the code test?

First, I checked the Callbook to make sure my leg wasn't being pulled by the call. That's a call I'd pay good money for. Look, Stephen, the ARRL is going to do whatever it takes to preserve the code test. The League directors I've known have always said that Novices and Techs aren't really hams, so you can bet their interests are not being considered. A high percentage of the no-coders do not read any ham magazine. Too technical. They aren't interested, by and large, in upgrading. 2m repeaters beats the heck out of CB, and that's that ... Wayne.

Mike Carbaugh WA3HDQ. I've had my ticket since the 10th grade, in 1967. I worked a lot of 6m AM and 2m FM back when 2m was fun. It seems like nowadays each repeater has its own little "group," but I still use an HT in my car during my 52-mile daily commute. I faded away from hamming in the late '70s, but came back when Techs got 10m. I'm using a 40m dipole, thanks to an article in your magazine. I just bought a PK-88 TNC and am looking for a PC. I joined AMSAT and listen to the "birds." The 2m/10m crosslink repeaters are a lot of fun. Try them, if there are any in your area. Clubs should do more for newer hams, and let them do some operating on Field Day, and during contests and special events. And cut down on the business meetings!

On my last 125 10m contacts, 63 were Novice or Tech, 20 were Generals, 24 Advanced, and 18 Extras. Techs seem to have revived activity on the band. I agree with you, and so do many other silent hams: To hell with the code! It's holding many good potential hams back.

If readers will send in a list of the repeaters which offer crossband contacts, I'd love to print a list. Give me the input channel, any coding required, and output crossband frequencies. Back in 1970 my WR1AAB repeater could be toggled to 6m or 10m by users, and it was a ball to use ... Wayne.

Larry Pitt KBØMOT. Wayne, I like your editorials, but I disagree with your comments on the code requirements for the General license. I'm a Tech-Plus, after starting as a no-code Tech. I'll soon be a General. I enjoy the challenge of the code. Don't make the ticket an easy thing to get. I like CW and have purchased a Bencher paddle and top-of-the-line MFJ keyer. I'll bet this letter won't be in the magazine.

You lose! CW is fun and thousands of hams are having a great time using it. But at a time when we are desperate for more hams, the artificial barrier to the hobby could lose everything for us. So let's get in as many newcomers as we can and then sell them on the fun of using the code. You apparently have no problem with the government telling you what to do, whether it makes sense in view of today's technology or not. I am a big fan of small government, and a minimum of it telling us what we have to do. And, other than being a fun mode of communications for us, CW has little else to offer these days. It's as out of date as spark and smoke signals. When I first got on the air in 1938 95% of all ham contacts were via CW. The latest estimates put CW activity at about 5% ... Wayne.

Pete Theiler KI4KN. I always enjoy reading your editorials and, based on your recommendations, I have been reading about the influences of electric and magnetic fields on life processes. Years ago, a friend of mine in Europe used a device that passed a minute electric current (on the order of 50-200 µA) through the body. This was simply a battery, pot, and electrodes. I think it was a commercial device. My friend suffered from fainting spells and other disorders. He swore the device helped him by stimulating his blood circulation and that it also speeded up healing. I had not taken any of this too seriously until I began to read Dr. Becker's *Cross Currents* and decided that there may be something to it. Thanks for your help and keep giving us hell in your editorials; most of us are just too complacent.

Bob Beck's latest claims are that he has over 200 authenti-

cated AIDS cures, with no known failures so far. But is this enough to interest AIDS activists? No, let's budget a few more hundreds of millions of government money into research for a drug cure ... Wayne.

Ken Young KD4WXW. I have been reading your editorials for a year or so and agree with many of your ideas and suggestions. I'm 15 and have had my license for several years now, but my friends in high school don't really understand anything about our hobby. Last year I decided to start a radio club for my high school and I've managed to get several members. I now have the respect of my classmates and teachers. Do you have any ideas to help attract attention to the club and help build its growth? I love your magazine, especially the antenna construction articles and editorials. Keep it up.

Thanks, Ken, and of course I have ideas on how to build the club. #1 is promotion, and that means articles, letters, meeting notices, activity reports in the school paper, on the school bulletin board, the local newspaper, TV and radio stations. Your members will do more if they're asked to and it's fun. Get any ham manufacturers or dealers in the area to come and talk. Club meetings are show biz where you get local hams active on packet, satellites, DXing, etc., to come and talk. Keep the business part of the meetings to a maximum of 10 minutes. There, that ought to keep you busy. Report back on progress ... Wayne.

Charles Leggatt VE3CFL. Bringing your readers up to date, May of 1997 will be the 500th anniversary of Giovani Caboto's sail from Bristol, England, to find the lands of the Great Khan. This was two years after Columbus had sailed south and discovered the Caribbean Islands, so it was a time of considerable interest in trying to find a sea route to China and the wealth that its silk trade could bring. There is no written proof of where he actually landed, but Newfoundland claims the honor, so that is that.

What is interesting about the area of Newfoundland and Labrador is that 200 years before the Pilgrim fathers set foot in America there was a community of some 1,300 souls who set up a whaling community in Labrador to process whale blubber. After several years, when it became no longer viable, they left, and only their big iron pots are left to remind us of their history. Since no effort was made to plant a flag and claim the land, it remained to be officially discovered.

The British, as you may have heard, have built a replica of Caboto's vessel, *The Matthew*. It has been undergoing sea trials for some months now and seems to be able to take a good bashing without sinking. It will set sail from Bristol, England, in May 1997, its destination Bonavista, Newfoundland. There will be 45 days of celebration with *The Matthew* circumnavigating the island. After that, it will proceed to the U.S.A. for further celebrations. The Cabot family tree extends to the U.S.A., and perhaps the most obvious member is your famous Cabot-Lodge.

What is Canada doing? Well, to start with, Newfoundland has really gone all out to prepare for *The Matthew*'s arrival. The Brits held a wonderful week of festivities in Bristol called The Festival of the Sea. Including Canada, five nations were represented and more than seven hundred vessels from all over the world were huddled in Bristol Harbor. Newfoundland, the Brits told us, had the best contingent of all the countries visiting, and since I was there, I can vouch for their correctness.

In Toronto, just under two years ago, a couple of Toronto sailors, Robert O'Brien of the National Yacht Club and John Dunford from the Mimico Cruising Club (both ex-Newfoundlanders), decided it would be a grand idea to get together a bunch of fellow sailors and sail the 1,900

Hams Turn Out In Airline Disaster

Some 125 Hams from the Greater New York City/Long Island vicinity contributed more than 2500 volunteer hours to support recovery operations in the wake of the TWA Flight 800 disaster on July 17.

The New York City Red Cross originally requested communication to Suffolk, which was arranged on UHF, linking Nassau and Suffolk Counties and New York City. A call also went out to Sid Wolen K2LJH, of Azden in New Hyde Park, New York, to supply additional radios, which the company was able to do.

As the situation developed, the Red Cross's mission became feeding the 2000 to 3000 rescue workers at the "crash site" (US Coast Guard Station) and to provide mental health support for the workers and the victims' families. The local telephone company, NYNEX, donated cell phones, but these initially were useless, with 3000 rescue workers and thousands of members of the press severely overloading the local cell. NYNEX set up a high-capacity site the second day, but that had its limitations also.

Ham radio worked, however, and ARES organizations were able to provide communications links between the American Red Cross HQ in Yaphank, New York, the lead Red Cross official at the site, and the Red Cross official at the morgue.

Although the recovery efforts continue, amateur radio support concluded during the last weekend in July.

Walt Wenzel KA2RGI, of the Region IV RACES, offered some lessons learned during the support effort. Among them:

You can't always count on 2m repeaters alone to provide coverage (the Flight 800 recovery effort, in fact, relied on a 70cm repeater).

ECs should keep a database of available equipment that can be loaned to operators who turn out.

Prospective volunteers should be reminded that while duty shifts are usually eight hours, they can often be 10 or 12 hours long. "People have to remember that having two batteries does not mean they have long-term power for handhelds," said Wenzel.

Coordination among ECs is key to success and individual volunteers must also coordinate their involvement with those in charge and not "just show up to assist." Volunteers also should not make statements to the media as this just adds to the confusion.

Even those with little or no public service experience can be valuable in an emergency situation, Wenzel said. "Do not think because you have not been involved for long with emergency communications or amateur radio that you cannot assist," he said. "Most people that can assist are new and are learning, and if you have checked into club nets and ARES or RACES nets, then you have the basics needed to assist." From *Harmonics*, official publication of the South Jersey Radio Association.

Newly Discovered Computer Viruses

•FEDERAL BUREAUCRAT VIRUS: Divides your hard disk into hundreds of little units, each of which does practically nothing, but all of which claim to be the most important part of your computer.

•PAT BUCHANAN VIRUS: Your system works fine, but it complains loudly about foreign software.

•PBS VIRUS: Your programs stop every few minutes to ask for money.

•ELVIS VIRUS: Your computer gets fat, slow, and lazy, then self-destructs, only to resurface at shopping malls and service stations across rural America.

•ROSS PEROT VIRUS: Activates every component in your system, just before the whole thing quits. Then space aliens land at your daughter's wedding.

It's a Bird! It's a Plane! No, it's...

A joint AMSAT-Germany/AMSAT-North America presentation in July announced that the next ESA (European Space Agency) Ariane 5 mission, AR 502, launch will be carrying AMSAT's Phase 3-D International Satellite.

After the failure of the first Ariane 5 launch in June, a board of inquiry presented the ESA with recommendations that should be considered for the next mission. Dr. Meinzer, Phase 3-D project leader, was quoted saying, "We have been given strong assurances that ESA has taken the recommendations of the AR 501 Inquiry Board to heart and are now 'rolling up their shirtsleeves' to correct those deficiencies in time for the Ariane 502 launch. I am sure that the ESA will do all that can possibly be done to insure our launch is successful."

AMSAT is committed to promoting space and communication research by constructing and controlling amateur radio spacecraft. It is a non-profit organization that has been employing volunteer labor and using donated materials and services along with governmental assistance for over twenty-five years. To date it has launched over two dozen communications satellites.

From *AMSAT News Release* #96-05.

Generous QRPers

One quietly altruistic event during the fun of the "Four Days in May" at Dayton this year was the collection of several hundred dollars to purchase solar panels for lighting in a small, very poor village in El Salvador. The panels will be taken to El Salvador this winter by Jo-Anna Dobbs GØOWH, who will spend a month working with a support group for the village. Mrs. Dobbs, wife of Rev. George Dobbs G3RJV, of Lancashire, England, takes unpaid work leave and provides her own fare. All funds raised by the support group go directly to the village, for primary health care and co-operative production.

Also, for many years, usually unknown to members, the G-QRP Club has sent free *SPRATs*, books and parts to many people in the third world who want to be involved in amateur radio but lack the funds. This year, in conjunction with NorCal, the G-QRP Club plans to ship 20 Epiphyte SSB kits to Asia for young amateurs who cannot buy equipment. Current plans are to ship kits to India and Pakistan, but suggestions from overseas members about other potential recipients are welcome.

Taken from an editorial by Rev. George Dobbs G3RJV, in *SPRAT, The Journal of the G-QRP Club.*

Radio Lollipop

Miami Children's Hospital has the first in-hospital pediatric radio station in the country: *Radio Lollipop*, staffed by volunteers, hospital staff, and patients, will broadcast live from a booth adjacent to the Child Life Playroom.

"*Radio Lollipop* provides hospitalized children with a way to escape the boundaries of illness by using their imaginations and becoming active participants in programming," says Renay Blanchette Rouse, project manager. The children will be able to take part in the programs, choose records, or answer quizzes by using special phones from their bedsides.

Radio Lollipop is an international not-for-profit organization established in 16 major children's hospitals around the world, including Great Britain, Australia, and New Zealand. It was first launched in 1979.

NEVER SAY DIE

Continued from page 4

seemed worth checking out when palladium and deuterium were put in a lithium bath. It was much the same with Hydrosonics in Georgia, which has been manufacturing steam heating systems that use a new approach to water compression to heat the water. Then their customers started remarking on how efficient their systems were, so they tested one and found it was more than 100% efficient. Hey, what's going on here?

What fields have you become an expert in? For that matter, what have you done with your life that has contributed even a little bit to the advancement of society? One of the things that really disappointed me when I started going to the reunions of my old submarine buddies from WWII was that few of them had ever done anything of any significance since our time on the submarine. Indeed, that was the most important thing many of them have ever done.

It just isn't that difficult to become an expert in some field. In almost any field. When the microcomputer came along in 1975 I decided I'd have to learn how the darned things worked. I went out and bought a stack of books on computer theory and started reading. When I found them almost impossible to understand (they were terrible ... college texts), that gave me the idea to start *Byte*. I knew there would be hundreds of thousands of people in the same fix as a result of this revolutionary development.

No one knows yet how cold fusion actually works, so anyone new to the field is starting out fresh. Actually, a newcomer has an advantage. One of the things that has hurt cold fusion has been the know-nothing scientists who, because they don't have an explanation for what's happening, have been refusing to believe it. Their position is that every one of the research labs that has claimed positive results has made serious errors. It can't happen. It hasn't happened. Everyone is mistaken. One scientist, Professor John Huizenga of the University of Rochester, and one journalist, Gary Taubs, have staked their reputations on this with books they've published.

Amateurs have a great advantage in that they aren't limited by what they know, only by what they don't know.

So the next time you start reading about digital voice, digital data compression, video compression, or a crypto algorithm, don't blonk out your eyes like that stupid old orphan and her 70-year-old dog; put on your pioneer hat and head for the hills of learning. How's that for some creative clichés? Blonk that metaphor!

Black & White

I'll bet you didn't know that the argot spoken by blacks was originally a white language. That's right, what is now spoken by our uneducated poor blacks came over from the south and west of England in the 17th

Switching Power Supplies

Different Is Good!

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

Let's review: An AC line operated linear supply normally consists of a step-up or step-down power transformer, followed by a diode rectifier, dual-diode rectifier pair, or a four-diode bridge rectifier package. The transformer's output voltage is applied to the rectifier circuit and the pulsating DC output from the rectifier is then sent on to be filtered by an RC (resistor/capacitor) or an LC (inductor/capacitor) filter section. The resulting voltage is then either used directly, or further processed by one of the many solid-state regulator circuits that are available to the equipment designer today. The entire process is easy for most of us to picture, and entirely linear (non-digital) in its makeup. This is the typical power supply that we've all learned to build and troubleshoot.

But just when you thought that you had it all down pat, along comes those new "switching power supplies" to add confusion! What gives? Is this just someone's brainchild to make life complicated, or are there real-life advantages to switching supplies?

As it turns out, switching power supplies really do have several advantages going for them. Traditional linear supplies are shamefully inefficient. They're often 50% (or less) efficient! That means that only half (sometimes less) of the input power is converted into the operational power needed by the device being run from the supply and the rest is dissipated as heat. One reason for this high level of inefficiency lies in the amount of "overhead" voltage necessary (the over- voltage needed ahead of the regulator circuit to make sure that it maintains regulation over widely fluctuating current demands). Another is the difficulty (and expense) in designing an efficient 60 Hz power conversion transformer. By contrast, switching supplies can be designed to be 85% efficient or better, resulting in considerably less heat loss and in less need for robust components within the supply to dissipate that heat. Switching supplies are smarter, smaller, lighter, and produce less wasted heat than do their linear counterparts.

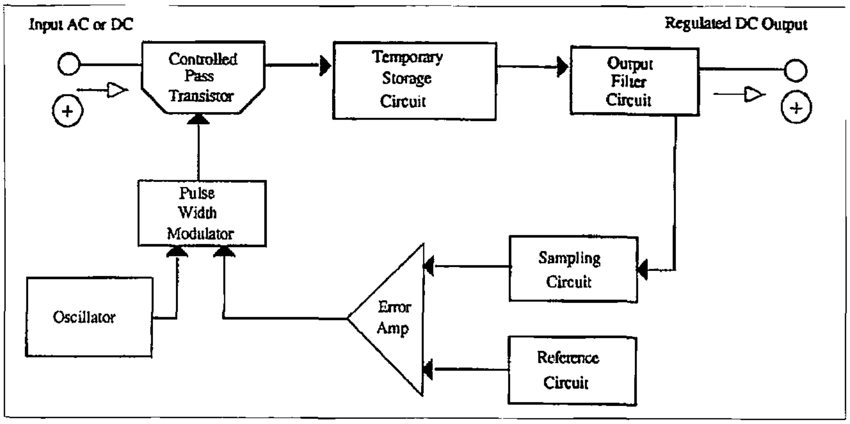

Fig. 1. The block diagram of a switching power supply.

But that's not all!

There are additional advantages to switching supplies. They'll operate over a greater range of voltages and currents than will a linear supply; the input voltage can actually be lower than the output voltage; and the output voltage can be of the opposite polarity from the input voltage. These last two features are not even *possible* with true linear supplies.

How is all of this accomplished? It's getting more and more important for all of us to know how, because switching supplies are showing up more frequently in computers, video monitors, consumer electronics, and of course, amateur gear. In order to be able to troubleshoot switching supplies when something goes awry, we have to at least be minimally familiar with the theory of operation of these relatively new devices, so here we go. Follow along with the help of the block diagram in **Fig. 1** while we explore the various elements that make up an average switching supply—it's not all that tough—just a different way of looking at power supplies.

The nitty-gritties

It's easiest if we begin with a slightly different mindset than when we're thinking about linear supplies. Instead of actual voltages and currents, I'll be using the term "energy" (which is what voltage and current really is) and then view what happens to this energy in terms of circuit "blocks" instead of tracking the electrons though each component part. I think that it makes it easier to picture what's happening.

The input rectified line voltage is first introduced into a controlled pass transistor block (shown in **Fig. 1**), much like a pass transistor regulator circuit in a linear supply. Immediately following the control device is a temporary storage circuit. It consists of an inductor, a capacitor and a diode. The temporary storage section is important, and something of a deviation from what we normally think of as the typical filtering section in a linear supply. To understand what happens, cast your mind back to Electronics 101: An inductor opposes any change in current (by developing a counter EMF) and is able to store energy within its own magnetic field. If neither of these properties of inductors sounds particularly familiar to you, you might want to go back and study up a bit on inductors in any basic electronics text, or you can simply take them on faith, but it's important to keep them in mind when analyzing how a switching supply does what it does.

Basically, when an inductor begins to carry current, its counter EMF opposes the change, causing the current to increase at a logarithmic rate, rather than all at once. The same effect is true in reverse; when the inductor is giving up its energy, there's a "reluctance" to the change, and the decrease is likewise at a logarithmic rate. This permits the inductor to store and release energy at a naturally controlled rate and facilitates the action of the switching power circuitry.

Jump over to **Fig. 2** momentarily. Once the supply is operational and the inductor has built up a magnetic field around itself, it supplies the energy stored in its magnetic field to the capacitor which acts as a reservoir for that energy, holding it until it's needed by the load (the device being powered). So the inductor and capacitor work in tandem, building up the energy to the level deemed necessary in the design, temporarily storing it, then releasing it as needed into the circuitry being powered in a controlled fashion. The diode in **Fig. 2** simply provides the directional path for current flow.

"These last two features are not even* possible *with true linear supplies."

Now, here's the neat part:

The control element that I mentioned earlier determines how much energy will be permitted to build up within the temporary storage circuit, based upon the demands of the final load circuitry. It does this by monitoring the "ideal" design energy level, and then automatically adjusting the control element to permit more or less energy into the storage block, based upon that design ideal. Unlike the normal regulator circuit in a linear power supply, however, the control element in a switching supply pulses the pass transistor on and off, many times each second, and varies the duration (or duty cycle) of those pulses, to match the energy level needed by the final circuitry being powered. It's called pulse-width modulation and it can react very quickly and efficiently to meter the amount of energy permitted to pass through the temporary storage block, all within fractions of a second.

Going back to **Fig. 1**, we see that the output of the temporary storage circuit is fed into an output filter circuit (or block) and on to the load. But a sampling of the output is also fed into an error amp, along with a reference voltage. A reference oscillator's output is fed to the pulse width modulator and used to determine the number of pulses sent to the control element each second. An error voltage from the output sampling and reference circuit blocks is also fed into the pulse width modulator and used to determine exactly how wide those pulses will be. It's similar to a phase-locked loop in a digital frequency synthesizer in some respects, but the analogy shouldn't be carried too far. A switching power supply is unique, but not completely unlike other circuitry common in ham gear these days.

It's important to remember that the output sampling block, the feedback block, and the reference oscillator block all exist to inform the control element how much outside energy to permit into the storage loop block at any instant in time. Thinking in these terms requires that mindset mentioned earlier—somewhat different than when analyzing how a conventional linear power supply works. The pulse-width modulation (or duty-cycle modulation) places the theory of a switching supply more into the digital domain than in the linear or analog domain. The control element of the supply is pulsed on and off, using pulses of varying duration, rather than a continuous and smoothly varying sampling voltage as in a linear supply. Perhaps now you can agree why looking at a switching power supply in terms of blocks or sections is easier to visualize. Since switching supplies are somewhat complex, breaking the supply down into these categories lessens the confusion that might otherwise result when first looking at the schematic diagram of

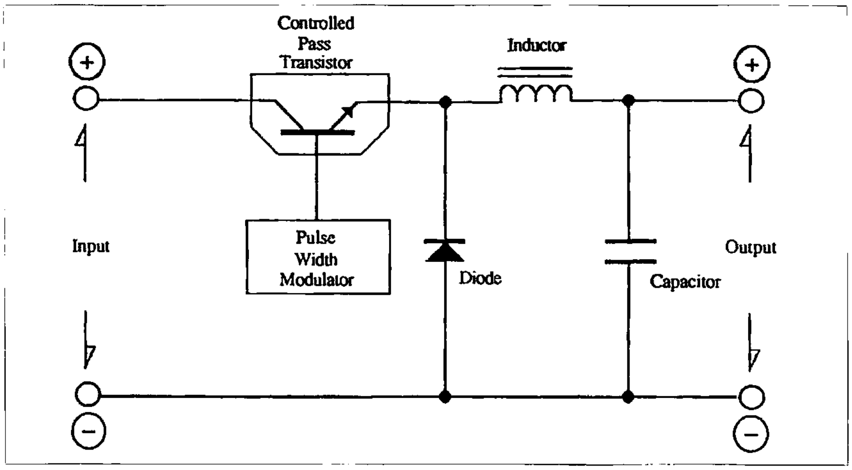

Fig. 2. In this step-down circuit, the output voltage is lower than the input voltage by a given amount and the output is primarily supplied by the discharging of the capacitor, with some additional energy supplied by the inductor as needed, but the inductor's main function is to replenish the charge on the capacitor.

one of these odd-looking ducks. Thinking in terms of blocks or sections also can be helpful in troubleshooting a switching supply—by examining what is and what is not present—in terms of all of the necessary elements.

The three basic types

Getting back to some of the details now, I mentioned earlier that a switching supply can either step up or step down the input voltage, even if the input voltage is lower than the desired output voltage. Stepping down is easiest to see; when the supply is operating normally, energy stored in the inductor's magnetic field and in the capacitor's dielectric is supplied to the output load circuitry via the capacitor's discharging—with the inductor recharging the capacitor as well as supplying some of the load current itself. Remember also that the temporary storage section component configuration in **Fig. 2** is used for this purpose. When stepping up the output voltage, however, the temporary storage section is configured somewhat differently (see **Fig. 3**), with the result that the inductor's energy is summed with the capacitor's energy, in a circuit that's reminiscent of the classical cascaded voltage doubler circuit. That configuration results in a higher voltage on the output than was present on the input for low current demand applications. When polarity inversion is called for, the control and storage elements are configured differently again (see **Fig. 4**), resulting in the positive and negative sense changing positions between the input and output. It does this by allowing the inductor to reverse charge the capacitor. Once again, **Fig. 2, 3** and **4** show each of the three possible conditions and the basic control/storage element configurations needed to achieve them.

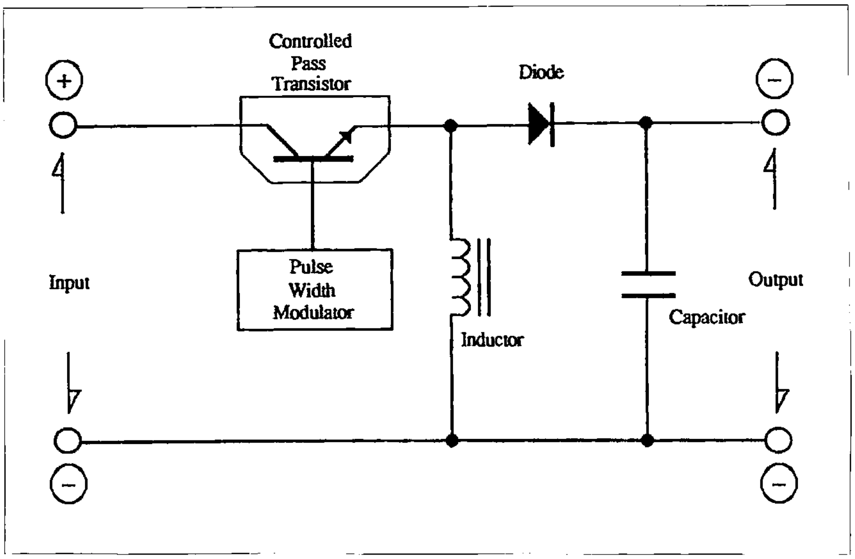

Fig. 4. *This polarity inverting circuit functions as a "flyback" circuit, supplying energy from both the inductor and the capacitor, but with the inductor charging the capacitor in a reverse direction from the input polarity sense. An inverting circuit like the one shown can be either step-up or step-down in terms of the final amount of output voltage.*

A somewhat different approach

Another variation on the switching power supply, one that finds its home in higher current applications (such as might be found when powering a typical 100 W amateur HF transceiver), is shown in **Fig. 5**. Instead of using a relatively heavy and inefficient 120V to low-voltage-transformer (as older linear supplies would do), this line-voltage-to-14V supply first rectifies the 120 volts, filters it, and applies the high-DC line voltage to a pair of transistor driver stages. These driver stages are switched on and off at a high frequency (controlled by the driver oscillator) and this high-frequency pulsating DC then is stepped down to a high-current, low-voltage DC by a more efficient high-frequency transformer and a pair of high-current switching diodes. The advantage is a much lighter, smaller, more efficient transformer, and considerably easier to filter high-frequency pulsating DC. Better control over the amount of input energy is also possible by utilizing pulse modulation control circuitry as discussed before.

"The square waves generated in digital switching are rich in harmonic content."

The reduction in size and weight by using high frequency switching—as opposed to the 60 Hz line frequency

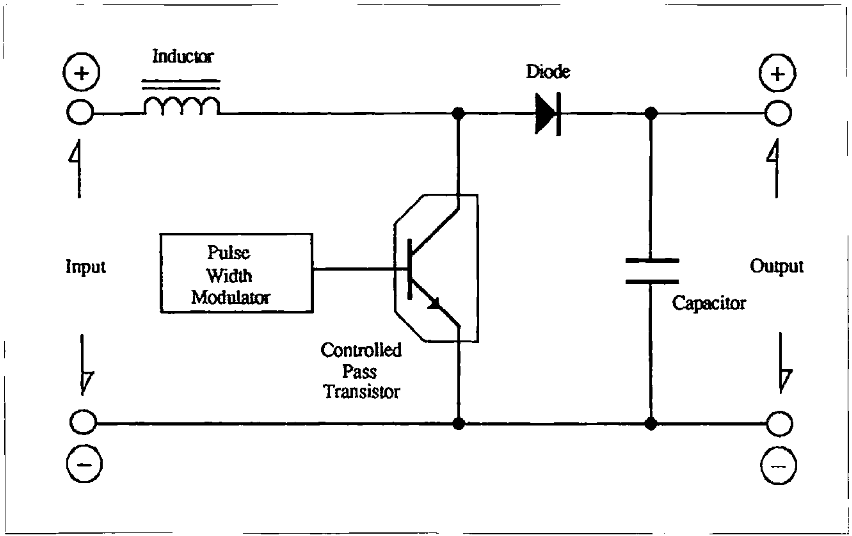

Fig. 3. *In this step-up circuit, the output voltage is higher by a given amount than the input voltage, since it consists of the cumulative total of the energy supplied by both the inductor and the capacitor.*

nautical miles to Newfoundland to meet up with *The Matthew* when it arrives in Bonavista. They called themselves "The Newfoundland Flotilla '97," and set about finding a few sailors who would be willing to brave the mighty St. Lawrence River and join them in the adventure. Well, they have certainly been successful, because at the time of writing some 76 sailors have signed up to be part of the Flotilla. This does not include some 25 American sailors who want to join the Flotilla in Bonavista. The Toronto Italian community is also involved, and they are considering a commitment to obtaining one hundred Flotilla sponsors at $10,000 apiece, the proceeds going to charity. The City of Toronto is sponsoring the Newfoundland Flotilla '97 Log Book, and all the skippers will be invited to City Hall for a luncheon and presentation of the Log Books just prior to their departure.

What about the ham side of things? Well, over a year ago I decided that a venture such as the Newfoundland Flotilla had to have a Chief Radio Officer and he could not qualify for that high title unless he could arrange a Special Events callsign. So I started with the Canadian Government Department of Communications. They naturally wanted full historical information, which was supplied, and then I waited. After a long wait, I phoned and asked why the delay, and was told that they thought that this was the first time in Canadian radio history that a maritime mobile unit had asked for a Special Events callsign. You see, Ontario's callsigns start with either VE or VA, followed by the number 3. Quebec has the number 2, the Maritime Provinces number 1, and Newfoundland starts with VO, not VE or VA. The Canadian Feds had to write to each of those Provinces and ask them to allow the Flotilla to pass through their territory without having to change the Special Events callsign. They got the Provinces to agree, and the Flotilla, when it sails in the May of '97, will do so with the callsign "CF3NYC." We have not set up a frequency and transmission time schedule yet, but that will be settled in the next two to three months.

If any of your readers want to find out more about the Newfoundland Flotilla '97 they can write to: Robert O'Brien, Chairman Newfoundland Flotilla '97, c/o National Yacht Club, 1 Stadium Road, Toronto, Ontario, Canada M5V 3H4. Or, E-mail: NFFLOTIL97@aol.com. CompuServe is: 75333,3243 @compuserve.com. There is a host of information available through these two mediums, so go to it. If there are any vessels who want to join the Flotilla write soon and get on the mailing list.

Darn, I sold my yacht! ... Wayne.

Bill Riley K9IMG. I enjoy reading your "Never Say Die" column. Recently, you mentioned the Council of La Raza, and that you did not know who they were. Another identical group is The Council por la Causa. These are Hispanic (Mexican) lobby groups that aim to get more federal funds.

They send their members to lobby the federal and state governments for more money, based upon their facts showing discrimination and a need for more and cheaper housing, housing repair, LIEAP (Low Income Energy Assistance Program) money, food banks, medical care, prenatal care, bilingual education, Head Start, ad infinitum. Our liberal Congress dutifully allocates more money. The federal agencies HUD, FEMA and DHSS collaborate with the Hispanics so they know exactly how to apply for these federal funds. The local agencies disburse the money, keeping 10% for administrative costs. This local agency can be a community action council, a council of government, immigrant services, or one of a number of peace and social justice coalitions.

These local agencies, always headed by a liberal activist Democrat, have a liberal activist Democrat staff that are all paid big salaries with a full range of benefits, even though most

Continued on page 69

switching—is quite dramatic, making for much more portability in high current supplies. One tradeoff that should be mentioned, however, is the potential for RFI from the power supply itself, especially when used near ham radio gear. This is true of all of the supplies talked about so far. The square waves generated in digital switching are rich in harmonic content; it's just a fact of life in the digital domain. Switching power supplies must be well designed, well constructed, and well shielded if operation near radio reception equipment is anticipated. Recognized name-brand supplies usually take every precaution in this area, but some RFI may still be experienced, just as with any other digital circuitry. Modern ferrite devices are generally used to help keep RFI from becoming an overwhelming concern, and all shielding must be replaced when these supplies are reinstated after troubleshooting.

Another difference between switching power supplies and their linear counterparts is in their cost; switching supplies are often 2 to 3 times more expensive because of the additional circuit complication and RFI proofing that's needed. There's a price for smaller size and greater efficiency, but it's often worth it.

Troubleshooting considerations

When troubleshooting a switching vs. a linear supply, the switching supply is much more difficult to analyze for faults. It's almost imperative that a schematic diagram be available; and a "theory of operation" and voltage chart can also be real timesavers. The best way to approach the problem is stage by stage. Try to isolate the fault on the basis of which stage, then which component in that stage, is behaving incorrectly. With the feedback loops at work, it's sometimes difficult to make that determination in a switching supply. If that's the case, try to analyze how the feedback loop can be interrupted and replaced with a fixed reference supply instead, just for the time being, until the problem can be isolated and corrected. This approach is sometimes the only way to avoid chasing your tail when working on any circuit that contains service-defying feedback stages.

"This approach is sometimes the only way to avoid chasing your tail when working on any circuit that contains service-defying feedback stages."

Most of the problems in switching supplies will be the same ones found in any other power supply—poor solder joints, broken wires, poor switch or variable control contacts, overheated parts, open or shorted components, or integrated circuits that are off-specification. Then there are the more esoteric problems! I ran into one recently myself, in a computer VGA color monitor using a switching power supply. It would change its width and brightness at times (because the regulated output voltage was changing), all by itself, and seemingly without any real reason, until I finally located the culprit. I was pretty well convinced that the controlled pass transistor package was the source of the problem, because tapping on it would often cause the fault to occur. I was ready to try hunting one down when I became suspicious of something else that the manufacturer had used in this particular monitor—a cream-colored adhesive that was used to hold some of the heavier parts down on the top of the printed circuit board. A couple of years back, I'd experienced similar adhesives becoming partially conductive as they aged, particularly when they became very brittle, as the adhesive on this board had. Furthermore, the way that the adhesive had been applied, a potential short circuit track existed between the line voltage bridge rectifier and the circuit common point, if in fact the adhesive itself had become partly conductive. Just on that bet, I removed (more correctly, chipped off) the adhesive in that area that would have completed a short, and as suspected, no more voltage variation. I removed the remainder of the adhesive in other locations just as a precaution, which only serves to illustrate that power supply problems come in many sizes and colors—just as in any other circuit! It's impossible to list all of the potential variations, but knowing how something is *supposed* to work, and playing a few hunches, can often pay dividends.

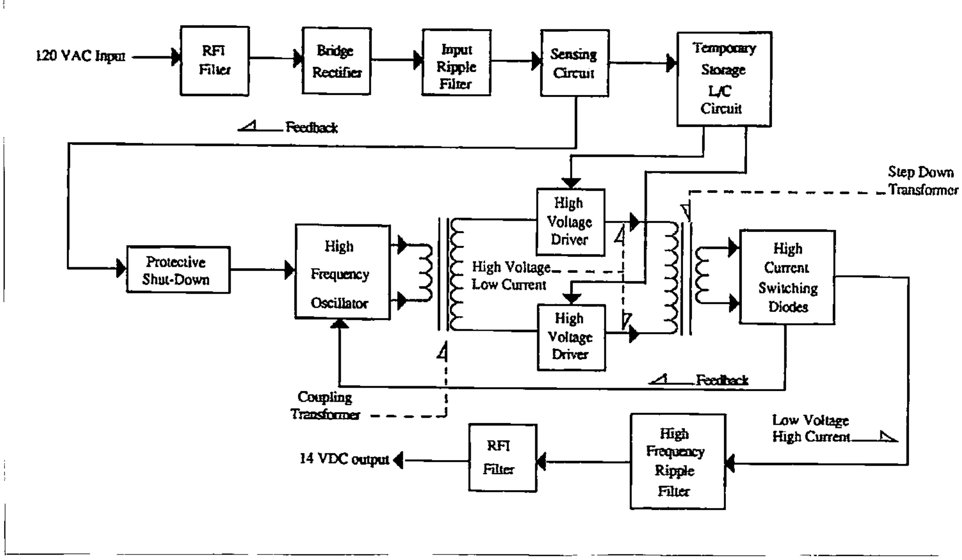

Fig. 5. One variation on a high current, low voltage high-frequency switching power supply from a recognized name-brand amateur radio equipment manufacturer.

Designing RF Probes

A simple one-hour test equipment project.

J. Frank Brumbaugh KB4ZGC
Box 30 - c/o Defendini
Salinas PR 00751-0030

An RF probe is used to directly measure the level of RF voltage present at a particular point. It is normally used with a digital multimeter (DMM) to indicate the voltage level as a DC voltage which is equivalent to the RMS value of the RF being sampled.

However, the level of RF being measured provides useful information only when the probe has been designed for use with a specific meter. The design of our RF probe is a function of the DC input resistance of the meter we intend to use with it. It can provide accurate information when used with a different meter that has the *same* DC input resistance, but will be inaccurate if the input resistance of the new meter differs from that for which the probe was designed.

Our probe design is somewhat unusual because we want to know the RMS value of the RF voltage we measure, and the probe actually detects and rectifies the peak RF voltage. Thus, it will be necessary to reduce the rectified DC derived from the peak voltage to a level equivalent to the RMS value of the RF at the probe tip. It is impossible to measure RMS voltage directly, except with a wide bandwidth oscilloscope. Therefore, we must design the probe circuit to do this for us.

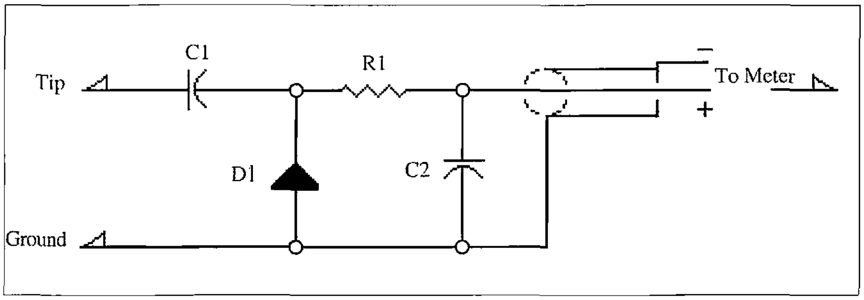

***Fig. 1.** It doesn't get much simpler than this.*

The circuit

Fortunately, this is simple. All we need to know is the DC input resistance of the specific meter. We'll use a commonly available full-function DMM which, in this example, has an input resistance of 10 megohms.

Fig. 1 shows the circuit of a common RF probe, easy to make and use. It's also very easy to design so it will be accurate. Cl and C2 are usually 0.01 µF monolithic or ceramic disc capacitors. Cl acts as a DC blocking capacitor to prevent any DC voltage at the tip from entering the probe. C2 is a filter capacitor to smooth any variations in the DC voltage rectified by Dl, normally a germanium diode.

"Can your analog meter be used instead?"

The rectified DC voltage at the cathode of D1 is at about the peak level of the RF voltage at the tip. Resistor Rl must have a value which will reduce this peak value to the desired RMS level. Because the peak voltage of a sine wave is 1.414 times the RMS value, Rl has to drop this excess voltage so the meter indication will be accurate. Because we know the meter has an input resistance of 10 megohms, we can calculate the value of Rl as follows:

$$10{,}000{,}000 \times 1.414 = 14{,}140{,}000$$
$$14{,}400{,}000 - 10{,}000{,}000 = 4{,}140{,}000 \text{ ohms (4.14 megohms)}$$

Rl should be 4.14 megohms (for use *only* with a DMM which has a 10 megohm input resistance).

This calculated 4.14 megs value is not a standard value, so we'll have to use two or three 1/4W resistors in series to make up the required value. We can either measure individual resistors from our stock of parts to come as close as we can, or we can do it the easy way by choosing 5% resistors and adding their value to come close to the desired value. For instance, a 2 megohm resistor and a 2.2 megohm resistor in series will produce 4.2 megohms, ±5%. Since this combination is only 60,000 ohms higher than needed, it is such a tiny percentage of over 4 megohms that it can be ignored. Electronics is a world of tolerances and percentages; as long as we come close to the value we need, it will work just fine.

Analog meters?

Can your analog meter be used instead? Sure, but you have to know the input resistance of the analog multimeter on the DC range setting you're going to use with your RF probe. For instance, there are FET multimeters available, most of which have a constant DC input resistance of 100k on all ranges, but this is the *only* type multimeter for which this

statement is correct. For this meter, Rl will have a calculated value of 41,400 ohms.

For other analog multimeters the input resistance will be different for each range. These meters are specified to have an input resistance of "X" ohms per volt. This value will be listed in the operator's manual or leaflet which is supplied with the meter or, in some cases, will be marked on the meter face.

Voltage

After you have determined the ohms-per-volt rating of your meter, you choose the specific voltage range with which you will use your RF probe. The full-scale voltage of this range will be used to calculate the value of Rl in **Fig. 1**.

As an example, consider a typical 20k ohms-per-volt multimeter, of which there have been more produced than probably any other except for the pocket-size 1k ohms-per-volt multimeters. We will calculate for both a 30-volt and a 50-volt range because these meters vary among manufacturers. You probably will have one or the other on your meter.

20,000 x 30 = 600,000 ohms input resistance
600,000 x 1.414 = 848,400
848,400 - 600,000 = 248,400 ohms (Rl)

20,000 x 50 = 1,000,000 ohms input resistance
1,000,000 x 1.414 = 1,414,000
1,414,400 - 1,000,000 = 414,000 ohms (R1)

Since we don't want to chance burning out Dl in our probe, we don't want to exceed the maximum allowable peak inverse voltage (PIV) that it can withstand. For the lN34 and lN34A the PIV is 60 volts. The lN270 will take 80 volts, the 1N191 will handle 90 volts, and the lN67A tops out with 100 PIV rating.

You may want to measure the RF voltage across a 50 ohm dummy load so the actual RF output power can be calculated. The peak RF voltage across 50 ohms will be from 10 volts at 1 watt to over 387 peak volts at 1,500 watts. A 100 watt transmitter will produce 100 peak volts across 50 ohms, so if Dl is a lN67A this would be an invitation for Murphy's Law to take effect. A 50 watt transmitter will produce more than 70 peak volts across 50 ohms, so we must be careful where we use the probe. It's a lot easier to build one than to fix it later.

It is possible to connect two or more of the same type diodes in series to replace D1 and increase the PIV rating of the probe. However, this practice will add stray reactance to the probe and affect its accuracy.

Although our RF probe is handy when working with transmitter powers of no more than about 30 watts, it is most useful when adjusting the RF voltages produced by VFOs, the local oscillator output to mixers in both transmitters and receivers, and intermediate stages and

"If D1 is an IN67A, it's an invitation for Murphy's Law to take effect."

some driver stages in transmitters. Power levels as low as 50 milliwatts will be easily detectable with our probe.

Construction

Now we need a probe body to put the circuit in, and we will need a metal tip. When the few components have been soldered together with very short leads, using a heat sink to protect the diode from the heat of soldering, we will need a shielded wire to connect the probe to the meter, and a red and a black plug to connect the shielded wire to the meter sockets. We will also need a ground lead and clip for the probe.

Depending upon the physical size of the component parts, especially Cl and C2, we can take apart a cheap office-type ball-point pen or a felt-tip pen for the probe body. RG-174 miniature coax, or even RG-58, can be used for the shielded wire. A small nail soldered to the lead of Cl makes a nice tip. A short length of insulated stranded wire and an alligator clip make a good probe ground.

For hams using low power—30 watts output or less—this probe plus Ohm's Law will allow the accurate measurement of RF power developed across a 50 ohm dummy load. The RMS voltage measured with the RF probe divided by the 50 ohm resistance of the dummy load will determine the RF current. Multiply the RF current in amperes by the RMS voltage to determine the power output in watts.

Parts List

C1, C2	0.01µF ceramic disc capacitor
D1	Germanium diode (see text)
R1	To be calculated (see text)

NEVER SAY DIE

century, brought over by English whites, who mainly settled in the South. The blacks are carrying on a heritage from their slave ancestors imported from England, not Africa. The development of public education in England eventually replaced this argot with standard English. Now it lives on in the American black culture, separating those who speak it from much hope of success in dealing with whites, or in getting well-paying jobs. It's one way blacks make sure that other blacks will provide a permanent black underclass.

Big Bummer

Yes, I've been on your case, trying to get you to stop sitting there like a lump in a bog and to stick a test prod into that jumble of gray goo in your head to jump-start some action. Our hobby is broke and needs fixing. Heck, it needs reinventing.

Sure, I keep coming up with ideas, but instead of generating your own in response, what I'm getting most of is apathy, with a secondary pile of kvetching. Yes, I'm complaining, but I'm not surprised or upset. After all, this is the same reaction I'm seeing to the call for ideas on how to solve our major social problems ... like welfare, the deficit, crime, the so-called drug war, and so on.

Heck, you're not even particularly upset over how much you're paying in taxes, which on the average these days is taking all of your wife's pay. And this is despite endless TV exposés showing you how your money is being wasted on crop supports to rich farmers (even tobacco supports!), rip-offs of virtually every federal bureau by crooks, enormous stockpiles of useless military supplies, and so on. There are a whole bunch of books exposing this stuff, showing where hundreds of billions are being wasted. Ho hum, right?

Getting back to amateur radio, I made a suggestion for a new approach to the hobby several years ago which just came back to

A Low Current Light

Great for portable operation.

J. Frank Brumbaugh KB4ZGC
Box 30 c/o Defendini
Salinas PR 00751-0030

Portable operation at night on camping trips poses a problem. Even the lowest current incandescent bulb eats a lot of power, so when your station is powered by a small gel cell battery, as are most portable QRP stations, every milliampere that can be saved for communications is precious. Also, the usual white light from a flashlight or even a pilot lamp is a magnet for every nearby flying insect.

There are "giant" LEDs 10 cm in diameter in clear plastic which produce a bright red light. They require 1.8 VDC at 20 mA. These are produced as replacements, several in a cluster, for automotive taillights and brake lights. I don't know of any source for these; I found one surplus several years ago and tried it out—I found that red light is no good for reading dials, meters, and switch positions. It also attracts its share of insects.

The best choice is yellow light. Unfortunately, most yellow LEDs produce very little light, and also require a dropping resistor which wastes precious milliamperes in heat. Much better are the T1-3/4 yellow LEDs (Mouser 509-HPY5066X). Nine of these 1.5V in series across a 12V battery draw only 17 mA, with no dropping resistor needed. And, because the LEDs have an expected life of 50,000 hours, they won't burn out just when you need them most.

Although using eight LEDs would seem to make more sense in a 12-volt system, the ninth LED helps to prevent excess current when a gel cell battery has been freshly charged and its terminal voltage exceeds 12 volts. It also allows the nine LEDs to be mounted in a 3 x 3 arrangement to concentrate the light.

> ***"Because these yellow LEDs have an expected life of 50,000 hours, they won't burn out just when you need them most."***

Construction

The LEDs should be mounted as close together as possible to better concentrate the light. Be sure to observe the correct polarity of each LED. The longer lead is the anode. While reverse polarity won't harm the LEDs, no light will be produced.

Although this is not the brightest light in the world, it will attract very few insects and the light produced is quite adequate for operating your rig and keeping a log. 73

Can You Top This?

The world's tallest mobile antenna?

Jim Ford N6JF
2415 College Drive
Costa Mesa CA 92626

If you've ever driven on Pacific Coast Highway in Huntington Beach, CA, or been at Southern California's TRW Ham Swapmeet, you've probably seen what is most likely the world's tallest mobile antenna. These have frequently been spots for Don Daily AA6GE to set it up.

It's mounted on top of his 1976 Ford van and can support many antennas, going from about 11 to 160 feet! Impossible, you say? Well, I thought so until I saw it.

You say, "This surely must be guyed." Well, it is, sometimes. At 160 feet the antenna is far from straight unless it is guyed, but he has driven around with it at 160 feet (1 mph?). Don, licensed since the mid '50s, and familiar for many years as WA6EKD, is no stranger to big projects. From Riverside (CA), in 1969 through 1971 he had an eight-element 105-foot boom 20 meter yagi on his homemade self-supporting 130-foot tower. It was secured with 20 tons of concrete! By profession, Don is a plant maintenance engineer and his knowledge of machine shop tools, processes, and materials is evident in all of his projects.

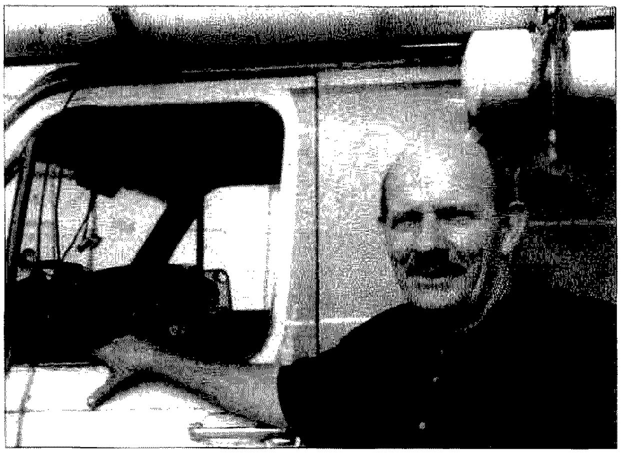

Photo A. Don Daily AA6GE.

The details

The bottom of his Space Needle, as he calls it, is made from 6.5 inches of 1/2" wall-thickness 7075 T6 aluminum. The remaining tubing is made from 6061 T6 aluminum, with the 120-foot level having a 2.5" OD. This was the level at picture time, with a rotator and small horizontal 2 meter beam at that point.

"It was secured with 20 tons of concrete!"

When in use as an antenna and not as a tower, it tapers to 3/4 of an inch at 150 feet. A CB-type whip adds an extra 10 feet, for a total of 160 feet. The pole is insulated from the van with four 1' x 1' x 1-1/4" phenolic blocks so it can be used as an antenna or tower. The total weight of all his antenna poles, which are stored in large-diameter white PVC tubes, is 800-900 pounds. The bottom section is guyed to his van with 1/2" braid, which is the type of line used on yachts and has a test strength of 18,000 pounds. The gin pole used for raising the antenna uses XLS 900 5/8" braid line rated at 27,000 pounds.

Don's experiences

Don doesn't always put up the 160-foot monster, but he frequently has antennas over 100 feet. Often, the only guys used are those that are attached to his van. He has mounted four 19-element 2 meter antennas on his Space Needle at 80 feet! He has setup time down to 45 minutes, and claims that there haven't been any scary wind episodes. He has operated a 70-foot antenna in 40 mph winds. Ham operation on 160 meters is difficult for many of us because of the large antenna length required, but Don likes the 160 band since he can put up a full-size 1/4 vertical!

When asked if he would rather have a motor home or house trailer, Don says no. He thinks a trailer or motor home might not be strong enough for his purposes, and besides, they would have a difficult time getting to some of the places where he likes to operate. He likes to operate as near the ocean as he can, to get the benefit of an ocean ground, or from mountain peaks for the quiet location and terrain enhancements. In his experience, a good HF mountaintop location is one which drops off rapidly.

To say he gets good signal reports from his van is an understatement, but the good reports are due in part to his ability to pick good locations. I visited

him one time when he was at a location near the top of Modjeska Peak in Orange County, CA. And I do mean the top because he definitely needed the winch mounted on the front of the van to get up the last 50 yards.

Don is planning a replacement for his aging '76 Ford van, but with all the customization and airbag suspension on his present van it may take a while to bring it up to his standards. Big-time mobile is not new to Don. He has used this van with somewhat smaller antennas for the 15 years I have known him. And yes, if you wondered, Don has been single since two years before the van.

Fully loaded, the van weighs as much as 10,300 pounds, but it was only 9,500 pounds at the time these pictures were taken. He is equipped with 10 100-pound batteries! This allows three- or four-day desert and mountain radio DX trips. He has worked over 250 countries and most of the US counties in this van.

Don is usually equipped for operation on 160 meters to 1296 MHz, but recently sold some of his less-used VHF and UHF gear and used the money for some of his other hobbies. He bought a trailer and mini 4WD military surplus vehicle called "The Mule" about a year ago and uses them for gold mining and astronomy trips. This allows him to carry two 650 watt generators, one 1 kW, and one 3.5 kW. The 3.5 kW generator is needed when he wants to use his kW HF amplifier, consisting of a pair of 3-500Z tubes. He also has solid-state amplifiers for VHF, and one for HF for battery operation when not running the tube amp. His well-secured van is a ham contest station on wheels.

***Photo B.** Looking up at 120 feet.*

I've seen this and many other of Don's antenna projects evolve over the last 15 years, but I am still amazed. Safely completing a project like this is not for many of us. Don would like to claim the world's highest mobile antenna. If you see AA6GE going down the road, give him a Morse code HI beep on the horn.

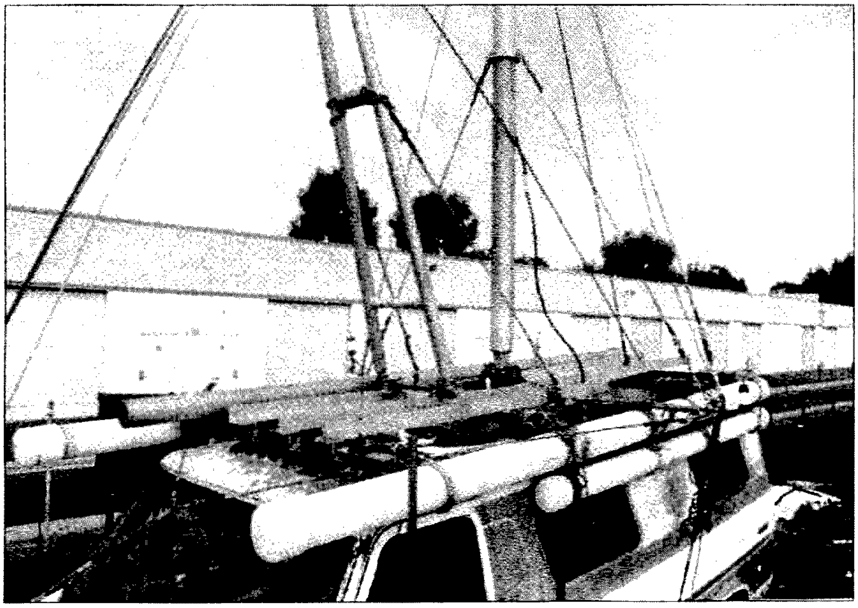

***Photo C.** Roof view. Do you think Don has ever been on a sailboat?*

The 48-46 Antenna

The CCD antenna is now available for the amateur bands.

Harry Longerich W4ANL
Rte 1, CV 9
Fredericksburg TX 78624

What is the 48-46 antenna? It consists of 48 pieces of wire interconnected with 46 capacitors. The technical name is "Controlled Current Distribution" antenna, or CCD. It's been around for a long time in the commercial broadcast field, and recently it was configured for use on the amateur bands. An excellent description and analysis of the CCD antenna is available in both References 1 and 2; these are worthwhile reading.

Rather than making a dipole out of two continuous lengths of wire, the CCD antenna uses capacitors to vary the phasing of the currents in the antenna to ensure that the most possible current is distributed to all sections of the antenna. These capacitors are inserted in series with the elements, about one every yard, for the complete length of each dipole element. In the 48-46 antenna each side of the dipole is made up of 23 capacitors and 24 sections of wire, each 35 inches long. The dipole is center-fed with open wire line via a transmatch. The 48-46 antenna uses a new approach to mounting the capacitors, and I also give some hints on how to build a simple RF detector to make sure the antenna currents are properly distributed.

Why consider a CCD antenna? Well, it has several distinct advantages over the conventional dipole:

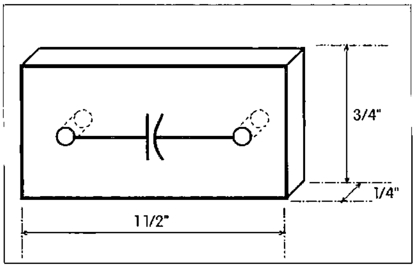

Fig. 1. Lucite or Lexan insulator with capacitor.

(1) It has about 3 to 4 dB gain over a conventional dipole at the basic design frequency.

(2) There are minimal high voltage loops on the antenna.

(3) There are no end effects of any consequence.

(4) The antenna may be erected in any manner, shape, or form—whatever suits your real estate.

(5) The entire antenna radiates. A dipole has about 67% radiation efficiency. The CCD approaches 97%.

(6) The CCD antenna, when used with an antenna system tuner, will have a gain on the fundamental design frequency and will operate on all higher amateur bands. It will not work properly on frequencies lower than the design frequency.

(7) The CCD antenna may be erected close to the ground without seriously affecting the efficiency of the radiated signal.

(8) This antenna is very quiet when used in the receive mode.

(9) Construction is straightforward (though time-consuming—96 solder connections are involved in building this type of antenna).

(10) The feed-point impedance will vary between 275 and 325 ohms, and will require the use of a balanced line or a 6:1 balun when used with a coaxial feedline.

Construction details

Initially, I built a 7 MHz CCD antenna. Though it is not difficult, construction does take some time. I started by cutting 48 pieces of wire, 35 inches long, with a 1-1/2-inch pigtail at each end, making each piece a total of 38 inches overall. I used Teflon™-covered wire, 16-gauge stranded. I used covered wire because here in Texas we have occasional severe weather, and precipitation static can be a problem. The covered wire reduces this type of static. Because there are no high voltage loops on the antenna, using covered wire does not cause undue losses.

In order to simplify measuring the wire to 35 inches, I built a simple jig on a piece of 1-inch by 2-inch wood, drove in two nails, 35 inches apart, and bent the wire at the 35-inch dimension. I judged the 1-1/2-inch pigtails. After cutting and stripping the 48 lengths of wire, I cut 49 pieces of Lucite™ (you can use Lexan™ if it's available) and drilled them as shown in **Fig. 1**. The Lucite insulator provides a means to connect adjacent wire elements as well as a way to mount the series capacitors.

"When conditions are right, I can copy European stations 5 x 9 plus on 75 meters."

When mounting the capacitor, it is important to provide sufficient capacitor lead slack to relieve stress on it. Obtaining the capacitors shouldn't be a problem. I bought 60 390 pF silver micas rated at 200 volts, with a tolerance of 5%. They cost nine cents each at a surplus outlet. The 200-volt rating will safely handle the legal amateur power level. One reason for buying 60 capacitors was to insure that I would have 46 capacitors that were within the 5% tolerance rating. Nine capacitors did not meet the requirements. Using polyester capacitors is better, but they are more

expensive. If possible, buy capacitors with long leads; it simplifies connecting them to the wire elements. Once the capacitors were mounted and connected to the wire elements, I covered them and the leads with RTV compound. This provides an excellent weather seal.

Check the current flow

Before you erect the antenna in its final location, install it about four feet above the ground. Remember, it does not have to be in a straight line; install it to suit your real estate. When you have erected the antenna at the four-foot level, use a simple RF sniffer (**Fig. 3**) and excite the antenna with 3-5 watts of power. Start at the feed point and work to either end of the antenna. At the feed point you will have some indication of current. It makes no difference what the reading is; whatever it is, use that as the reference reading. Work your way to the end of the antenna. As you approach a capacitor the reading will decrease a bit, but as you travel to the end of the wire element the reading should again increase. If a reading should drop off after moving away from the capacitor, you have a problem in that section. It could be a bad capacitor, broken lead, or poor solder connection. Correct this before proceeding further with the measurements. Remember: When making these measurements, do not change the power output of the exciter.

Installation

Once you have ascertained that the current flow is uniform throughout the entire length of the antenna, you are ready to install it on your real estate. The length of the feedline is immaterial but, of course, the shorter the better. The lowest point of my 3.5 MHz antenna is four feet high. The center of the antenna is about 35 feet, and it is mounted among 40-foot trees, through branches and close to buildings. When conditions are right, I can copy European stations 5 x 9 plus on 75 meters. The 7 MHz antenna is also among trees, and I can work VKs, 5 x 8 – 9, using 100 watts when propagation conditions warrant.

This is exciting

One of the problems of living in Central Texas is that ground conductivity is very poor. To overcome this, I installed a #16 copper wire, buried one inch in the ground, and followed the exact pattern of the erected antenna. Initially, when I excited the antenna with 5 watts, the RF sniffer indicated a reading of 29 microamperes. With the ground wire in place and 5 watts of excitation, the RF sniffer indicated 33 microamperes at the ends of the antenna. What this told me was that the antenna was passing more current, and the radiating efficiency had increased. Reference 2 states that the use of capacity-loading disc screens at the ends of the antenna will increase the radiation resistance, improve current distribution, and almost completely eliminate end effect. The end caps I use are illustrated in **Fig. 2**, and they are mounted vertically, about three feet above the ground wire. The resonant frequency of the antenna was lower, so I eliminated one section from each end and the frequency was about 6.995 MHz. I again excited the antenna with 5 watts and

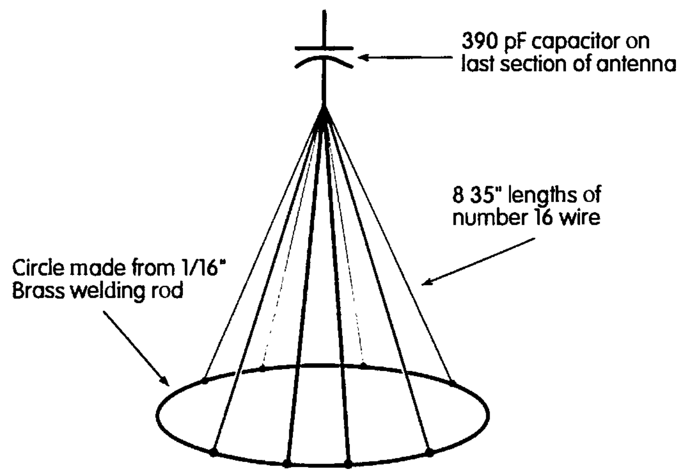

Fig. 2. End capacity hat for 7 MHz CCD antenna; two required.

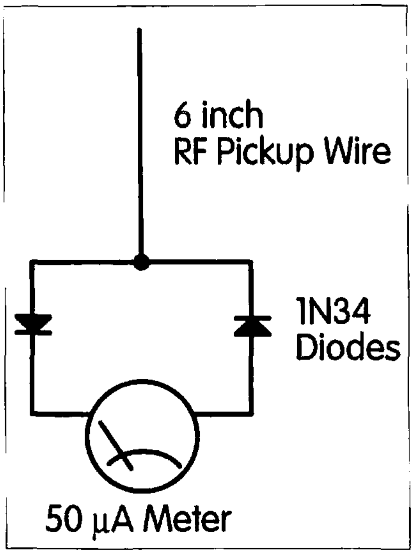

Fig. 3. RF sniffer (will operate up to 100 MHz).

the reading at the end cap was 41 microamperes, an increase of 8 microamperes—another substantial gain increase.

A word about feeding the antenna: If you plan to use coaxial cable, I suggest you use a 6:1 current balun mounted at the feed point of the antenna. The use of an antenna system tuner is a definite plus when using coaxial cable. I personally prefer using a balanced line. A good-grade 300-ohm TV twin lead will work well with powers up to 500 watts. A 450-ohm balanced line will also work. A tuner must be used with both of these lines.

Frequency check

Before you erect the antenna you may want to try to check the resonant frequency with a grid-dip meter. You'll be in for a surprise. My 7 MHz antenna resonates at 6.995 MHz, which is about normal for this type of antenna. You may, if you desire, cut off one or two sections from each end of the antenna to bring it into the 7 MHz range. I tried it, but it made no difference in the current readings or performance of the antenna. Remember: When grid-dipping an antenna, always make the measurements at the feed point of the antenna.

Try this tuner

A word about antenna system tuners: I built AG6K's Balanced Balanced Tuner[3] and it is a beauty. This tuner uses a balanced input system, which really makes good sense. I used a 1:1 current balun made with ferrite cores. The output of this tuner is balanced, no balun is required, and the efficiency is excellent. With my 7 MHz CCD antenna, I was able to obtain a 1:5:1 SWR from 7 MHz to 29.99 MHz. For those of you who like to experiment, I recommend trying this tuner. I have also used a conventional LC network tuner which worked very well, but it was a bit cumbersome when switching to bands other than 7 MHz. Any good grade of commercial tuner may also be used with good results.

Designer's choice

This antenna may be erected in any configuration that suits your real estate. I have erected them as inverted Vs, bi-square, and even lying on the ground. Rest assured, they will perform. My present goal now is to cut down some trees (when the XYL isn't looking) and try two 7 MHz CCDs, spaced about 18 feet apart, and reverse the feeds for east or west directivity. If anyone has had the opportunity to try this, or has any input on the CCD antenna, please let me know the results. 73

Number 25 on your Feedback card

Hamtronics R139 Weather Satellite Receiver

Enjoy monitoring atmospheric conditions and the satisfaction of building the kit!

Larry R. Antonuk WB9RRT
P.O. Box 452
Marlborough NH 03455

I'm not really sure *why* I got interested in satellite weather reception, but I remember exactly *when*. A member of the local radio club was putting on a demonstration at a club meeting. He had assembled a very simple interface, using perhaps a single chip and a cap or two built into a 25-pin D-sub connector hood. One end of this hooked to his receiver, the other end to his computer. Using a piece of demodulator software he obtained from the Internet (as freeware, no less), he was able to decode HF weather facsimile pictures—quite respectable pictures, too, except that most of them were of very interesting cloud formations out over unrecognizable areas of the ocean someplace. As my interest grew over the next few weeks, I found that most of these HF transmissions are intended for ships at sea. This meant that my chances of receiving highly detailed photos of the weather surrounding my home QTH in the hills of New Hampshire were pretty slim. However, while doing research on weather transmissions in general I found out about something even better than the HF transmissions. It was apparently possible to receive the broadcasts from the satellites themselves—in real time—as they were going overhead. This made much more sense than worrying about trying to capture some out-of-date military transmission on the HF bands. At the time I realized that this project would be a little more complicated than mounting an IC inside a DB-25 hood, but I decided to go ahead with it.

My research took me through several magazines, a few books, and one highly recommended manual (*The ARRL Weather Satellite Handbook*). I found that the satellites I wanted to receive all worked in the 137 MHz band. These were the American (NOAA), Chinese (Feng Yun), and Russian (METEOR) birds. The NOAA satellites were more "available"—that is, they passed overhead more often, and more of them were still transmitting useful data. In addition, the NOAA birds transmitted both visual and infrared images as they circled the earth. These satellites circle the earth in near-polar orbits, meaning that from a given location, each of them may be in range several times a day. In any case, there were three main components needed in any decent station capable of receiving the polar orbiting automatic picture transmission (APT) satellites—a receiver, a demodulator, and an antenna system. I felt that my first step should be the receiver. Once I had that built and could determine whether or not I could actually hear any satellites, well, then I could decide if I wanted to actually spend some money to find out what the pictures looked like.

"It's possible to receive the broadcasts from the satellites themselves—in real time—as they go overhead."

According to my sources, there were two main choices for the 137 MHz receiver. The first was an actual 137 MHz radio designed for satellite reception. The second was to use a modified scanner. The reason that an off-the-shelf scanner needed to be modified had to do with the bandwidth of the APT signal. The weather satellites transmit a signal modulated with a 2400 Hz tone, at ± 15 kHz deviation. This is three times the level used in most normal communications gear. While it would be possible to receive these signals on a normal receiver, much distortion would result due to the lack of modulation acceptance, and the results would be unsatisfactory. I found it was possible to modify a scanner to eliminate the IF selectivity, which would allow the wider signals to pass through. Unfortunately, this would allow unwanted signals to pass through as well. Since I lived near an airport I was already worried about the effect of the nearby aircraft band transmissions. I decided that a widened IF, coupled with the wide front end of the scanner, would be more trouble than it was worth. I decided to shell out the bucks for a real receiver.

Photo A. The completed R139 Weather Fax Receiver.

After reviewing the options, I chose the R139 Receiver from Hamtronics, Inc. The R139 represented a good compromise between cost, performance, and bells and whistles. The R139 comes as a five-channel crystal-controlled unit, with scanning capability. It has a 0.2 μV sensitivity, due to its low noise dual-gate FET RF amp circuitry. Modulation acceptance is 38 kHz, meaning it's designed just for the bandwidth of the polar orbiters. A tunable front end is

used to provide plenty of rejection to off-channel signals. The R139 also has separate outputs for speaker audio, demod output, and a special line to control a tape recorder. I found that I could save quite a few dollars by building it myself, so I ordered the kit.

Assembly of the main board took a couple of leisurely evenings, and I finished up the alignment and cabinet installation on a Saturday morning. As is usual for Hamtronics, the board and components were of very high quality. Documentation was not a step-by-step installation procedure—the builder is given some credit (and responsibility) for knowing what he or she is doing. The assembly instructions consist of about a dozen paragraphs, giving hints and pointers about each group of parts. More specifics are given about the size of parts to install at a given time than about which part goes where: "After a group of shorter parts like these are installed, you can put in taller parts like L3 and L2." This prevents the assembler from making any moves that will make life difficult later, while still giving him the responsibility to choose the order of assembly.

Once the assembly is complete, it's time for alignment. Note that you do indeed need a signal generator for this procedure (a friend with a signal generator works just as well). The documentation does provide step-by-step information on the alignment of the receiver, as well as several hints and suggestions as you go along. (Note that the slug-tuned coils require the use of a .062" square tuning tool. If you don't have one, make sure to order one along with the R139. They're cheap compared with the suffering experienced when you break a coil slug on Saturday night because you tried to use the wrong tool, and you can't get a new slug until Monday, and you'll never know all weekend if your receiver is working or not. Not that the author has ever had this experience...)

Once the unit is aligned, it's time to hook it up to the demodulator and the antenna. Connections are easily made through a 9-pin D-sub connector on the rear panel. My first attempt was simply to set the squelch and turn up the volume as I went about my business in the house. Within an hour I was hearing a reassuring "tick-tock" coming from the speaker, using just a VHF discone antenna. I hooked the demod output to a tape recorder, and connected the TAPE CONTROL output of the R139 to the REM IN of my tape recorder. Nothing happened. I figured that the open collector output in the R139 couldn't sink enough current to start the motor on my 1970s vintage tape recorder, so I added a small relay to do the job, which corrected the problem. (I later found that this was carefully explained in the part of the instructions I hadn't bothered to read, but that didn't diminish my feeling of accomplishment at having engineered the solution myself.) I started recording passes, and worked on figuring out how to get my demodulator to work.

The first several images I demodulated were confusing—nice cloud formations, some land masses—but I couldn't for the life of me figure out where they were being taken. I had no idea of the scale; was that chunk of land a peninsula on Cape Cod, or was it Florida, or maybe the tip of South America? Not only that, but since some passes are received going north to south, and some south to north, the upside-down land masses can be very difficult to recognize. (This inverted orientation can be corrected with the viewing software.) Finally, on a Saturday morning I heard a pass going over. I came into the shack and found that I was out of tape in the tape recorder, so I demodulated the image directly from the R139. As the picture crept down the screen, line by line, I could make out some clouds, then a big lake, then some more lakes, then—Hey! The Great Lakes! Nine-Land! My old stomping grounds! There were a few clouds over Minnesota and Lake Superior, but northern Wisconsin was as clear as a bell. Elated, I immediately called my parents (Harry and Jean) back in Wisconsin and informed them that I could tell they had clear weather at their house. They were quite unimpressed, even when I explained the amazing advances in technology that allowed me to tell them this. When you've lived from telegraphs to cell phones, and from crystal radios to CNN, I guess it's hard to be excited about a simple satellite receiver. But I sure was!

"A great way to get into satellite weather reception."

As the weeks passed, I collected more and more images, some impressive, some not so exciting. The R139 dutifully turned on the tape recorder and recorded each pass, whether it was going directly overhead or photographing someplace I wasn't interested in. In addition to these unwanted passes I found that I wasn't getting as large or as clear a picture as I should have. My simple discone antenna wasn't up to the task of pulling in enough signal for quality satellite photos; I obviously had to fine-tune the system. First, I needed to find out how to use my demodulator and software more effectively so I could choose the satellite and pass I was interested in. Second, I needed to upgrade my antenna system to something more appropriate to the demands of extra-terrestrial transmissions. But in the meantime, my Hamtronics R139 Weather Fax Receiver was pulling in the pictures, and I was busy printing out images to impress the guys at work.

All in all, the Hamtronics R139 Receiver is a great way to get into satellite weather reception. Although not a kit for the first-time builder, if you've got a project or two under your belt and have access to a signal generator for the alignment, the R139 is a top-notch receiver for the money. For more details contact: Hamtronics, Inc., 65 Moul Road, Hilton NY 14468-9535 or call: (715) 392-9430.

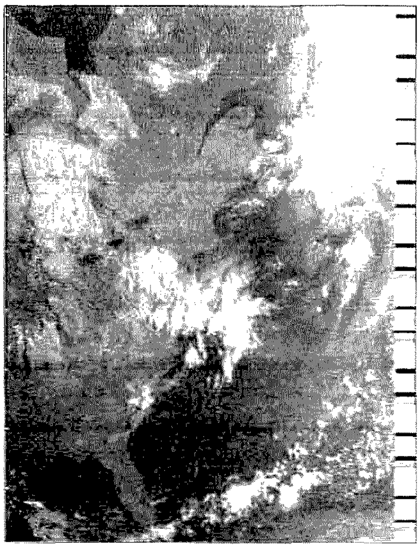

***Photo B**. A sunny day in New Hampshire. This infrared image stretches from the tip of Florida all the way north to the bottom of Hudson Bay. The bars on the right border are the synchronization signals that are transmitted at the beginning of each line.*

NEVER SAY DIE

Continued from page 18

mind. When I wrote a set of rules and regulations for Jordan back in 1970 I proposed something along this line, with the call prefixes reflecting the progress a Jordanian amateur had made.

The recent Boy Scout Jamboree On The Air (JOTA) reminded me of my idea of setting up a similar merit badge system for hams. We could have one for working all states on any particular band and mode. Another for working 100 countries on a band and mode. 20m-SSB, for instance. 40m-RTTY. 160m-CW. With badges for packet, slow-scan, satellites, and so on. If we want more CW activity, why not offer a badge and certificate for using CW to work and states and 100 countries? Ditto packet, and so on.

With a set of goals like that we wouldn't need six different license classes.

If You're So Smart ...

Okay, as a ham you are a communications expert. Well, you're supposed to be. That's what you've conned your non-ham friends and the FCC into thinking, right?

So what do you really know about communications, other than kerchunking some repeaters or adding still more garble to a pileup? If someone were to ask you about pagers, what could you tell them? How much do they cost? What's their range? Where do you get 'em? What frequencies do they use? What services are available? Can you use them around your own business?

And what can you tell people about fax-modems? The Internet, CompuServe, Prodigy, bulletin board systems, and so on?

There are almost endless communications services out there. Now, if you, as a bona fide federally licensed communications expert, can't answer even simple questions about 'em, imagine how confused the average business person is when faced with choices of telephone switches, cellular telephones, teleconferencing, security systems, computer networking, and so on. All this is so far beyond the average person to deal with that you have a tremendous opportunity to make some money ... once you know your stuff.

No, you don't know all the answers now, but with your ham background, at least you can understand the questions and you have some clues on where to find the answers. Knowledge is not only power these days, it's money. There are at least 10 million small businesses that could be benefited by better communications, security, and computer systems. That's one heck of a market.

How long do you think it would take you to become an expert on pagers, just to pick one field at random? You need to get literature from the manufacturers, dealers, and service companies. You'd want to read a couple books on the subject. Are we talking six months? One month? A week?

Next you'd want to visit some of the companies involved in the business and talk with them. Find out their problems, what success stories they have, which equipment they think works best, and so on. Couple months in your spare time?

Now that you have a good understanding of the technology and the players, and have the contacts you need, what should you do next? My recommendation would be to sit down at your computer and write a brief handbook on the subject ... maybe 32 pages. Write it for the nontechnical average business person. Explain the benefits your service provides and show how the costs are small compared to the benefits. You can make the handbook look professional by printing it on a laser printer. The first hundred copies can be made on a copy machine. That's the way I do my booklets until the demand gets out of hand.

This will provide you with some sales literature for your new communications consulting service. With your name as the author, this certifies that you are an expert. Now you're in a position to send letters to local businesses offering the first phase of your communications consulting services.

Once you know your stuff on pagers it's time to pick the next business you're going to learn. If you've made any efforts toward selling your pager expertise, by now you'll know what questions business people are asking about other communications services. You might tackle fax-modems next.

Same deal. Get the literature. Read the books. Talk with the manufacturers, dealers, and services. Help some friends for free, learning on their money. It's always best to use other people's money (OPM) as much as possible when you are learning.

Within a year, if you make any kind of an effort at all, you'll be Mr. Communications in your town, and you'll have dozens of small businesses turning to you for solutions. In the communications business you make money on sales, on installations, and on service. Great business. All communications equipment breaks, so the service business is wonderful. And computers, being the most complicated of all, break the most often. Plus there are viri, incompatible software, static electricity, errant magnets, and so on to help keep you living comfortably.

Oh yes, it won't hurt to become an expert on magnetic fields and go around with your gaussmeter and help people avoid possibly harmful fields. There are some inexpensive gaussmeters on the market that do a wonderful job.

And when your customers want to know whether cellular telephones are harmful or not, you'll know the answer and be able to give them a reprint of an article from *73* on the subject.

There's no reason for any ham with even the slightest amount of gumption not to be living in comfort and have as big a ham station and antenna farm as he (or she) wants.

Expert Help Needed

If you are already an expert on any phase of communications, how about writing an

A QRP SWR/Power Meter

Just by recalibrating the MFJ-860.

J. Frank Brumbaugh KB4ZGC
Box 30, c/o Defendini
Salinas PR 00751-0030

The MFJ-860 cross-needle SWR/PWR meter is a small 4-1/2" x 2-1/4" x 3" (WHD) lightweight instrument which provides simultaneous indications of SWR and forward and reflected RF power in two switch-selected ranges of 30 and 300 watts into a 50-ohm load. The meter face also includes a 0-to-6-watts scale which can be used for QRP operation after completing the modification in this article.

Only your QRP transmitter, a dummy load, and a small screwdriver are needed to do the job. After this modification there will be two ranges as before, but one will be 6 watts full-scale forward and the other will be 30 watts. No hole drilling or soldering will be necessary, unless you decide to add a switch and capacitor to provide a choice of average or peak output power.

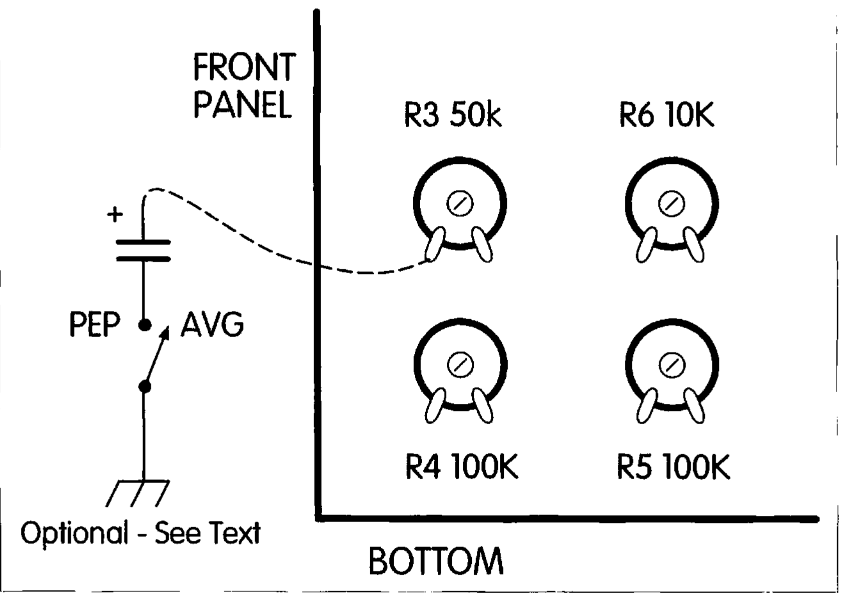

Fig. 1. Identification of calibration trimpots.

Calibration

Remove the two screws holding the clamshell case together and place the top aside. Turn the instrument with the right side facing you. You will see four black trimpots mounted at the upper left of the printed circuit board (**Fig. 1**). The upper row, from the panel side to the rear, control forward and reverse power levels on the current 30-watt range. This will be recalibrated to indicate 6 watts full-scale. The lower row of trimpots, from the panel side to the rear, control the forward and reverse power levels on the current 300-watt range. This range will be recalibrated to indicate 30 watts full-scale.

Because of the values of trimpots used by MFJ, recalibrating both ranges is easier than attempting to change the 300-watt range to indicate 6 watts full-scale.

Connect a 50-ohm dummy load to the antenna connector on the rear deck. Connect the output of your QRP transmitter to the transmitter connector on the rear deck. Put the range push-button switch on the panel to the 30-watt range. Turn on and key your QRP transmitter, setting it to any exact wattage between 1 and 6, but preferably 5 watts. **Note:** If you connect a coaxial tee to either connector on the rear you can use your RF probe and DMM to accurately set the RF power output. A reading of 15.81 volts indicates 5 watts into 50 ohms.

Assuming you have 5 watts of RF input, adjust R3 (50k) until the meter indicates 5 watts on the lower "Forward" scale on the meter face, midway between the numerals 4 and 6. This completes calibrating the 6-watt forward power range.

Now change the range switch on the panel to the 300-watt range. With the same 5 watts input, adjust R4 (100k) until the meter indicates 50 on the upper portion of the "Forward" scale. This point is 5 watts on the new 30-watt scale, and completes its calibration.

Now unkey your QRP transmitter and reverse the connections on the rear deck with the dummy load hooked up to the transmitter connector and your transmitter hooked up to the antenna connector.

Check that the range switch is still in the 300-watt position, key your transmitter to apply 5 watts in the reverse direction, and adjust R5 (100k) until the meter indicates 50 on the upper side of the reflected scale, then unkey your transmitter. This completes calibration for reflected power on the new 30-watt scale.

If you can reduce transmitter output power to 1 watt you can calibrate the reflected power range on the new 6-watt scale, as follows:

you can read SWR on either range. However, if you were unable to reduce power to 1 watt, and therefore could not calibrate the reverse range on the 6-watt forward range switch position, you won't be able to determine SWR on this range. In this case, tune up on the new 30-watt range where the SWR indication will be accurate.

"Only your QRP transmitter, a dummy load, and a small screwdriver are needed to do this job; no hole drilling or soldering are required."

Warning: Do not apply more than 1.2 watts in the reverse direction on the new 6-watt range—you can easily destroy the meter. Reduce power from your transmitter to 1 watt, a reading of 7.07 volts with the RF probe into 50 ohms. This should be indicated at 10 on the upper "Reflected" scale because the range switch is still set for 300 watts. Place the range switch in the 30-watt position (the new 6-watt range). Adjust R6 (10k) *very carefully* until the meter indicates 1 watt on the lower "Reflected" scale. This adjustment is touchy because 1 watt indicates with R6 very near the zero resistance end of its rotation. Unkey your transmitter. This completes recalibration of the MFJ-860. If desired, you may change the panel markings on the range switch from 30 to 6 watts, and 300 to 30 watts.

Adding Peak/Average Power Switching

Refer to **Fig. 1**. There is more than enough room on the panel, either between the meter and PC board or between the PC board and the right end of the panel, to mount a small toggle switch. The electrolytic capacitor (22 µF) is suggested, but you can use any size that provides the time constant you prefer when indicating peak power output. It can be tucked wherever it is convenient. Its voltage rating is unimportant because the leads carry only very few DC volts. With the toggle switch OFF, the meter will indicate average (rms) power. When the switch is ON, as when operating SSB, the meter will indicate peak RF power.

About SWR

The MFJ-860 meter is so calibrated that SWR is indicated on the red arc where the needles cross. The ideal situation is to show no reflected power, indicating an SWR of 1:1. If you were able to calibrate *both* reflected power ranges

Conclusion

Remember, when using the new 30-watt range, divide the power indication by 10 to determine your power output. For instance, 50 on the "Forward" scale indicates 5 watts output.

If you operate at or close to the 5-watt output level and use SSB, leave the meter set on the new 30-watt scale. The PEP of a nominal 5-watt SSB signal will peak at around 8 watts, which will be off-scale if you use the new 6-watt scale.

A Dirt-Cheap Broadband 80 Meter Vertical

The "outhouse" antenna.

Carroll R. Markivee WØRKU
71 Cedar Ridge
Eureka MO 63025

Efficiency is the hottest topic in antennas, according to articles I have read recently. In my book, the most efficient antenna is the one that puts out the most signal for the least money. That means using what you have or can get cheaply, both hardware and geography, to the best advantage. By my standards, one of the most efficient radiators is a length of wire and one of the most efficient supports is a tall tree or anything else that is high and dry.

The second most important topic is the SWR. Most 80m antennas have a low SWR over only two or three hundred kHz of the band. You have to choose the low end, the high end, or somewhere in the middle, but you usually can't operate over the entire band without an antenna tuner or transmatch.

The antenna I'm describing has a low SWR over almost all of the band. The SWR is less than 2:1 from 4.0 MHz. Down to 3.58 MHz! Below 3.58 MHz it's still below 2.5:1. You don't need to keep retuning a box to use this antenna. A single coil-and-capacitor matching section is used to connect the coax to the antenna.

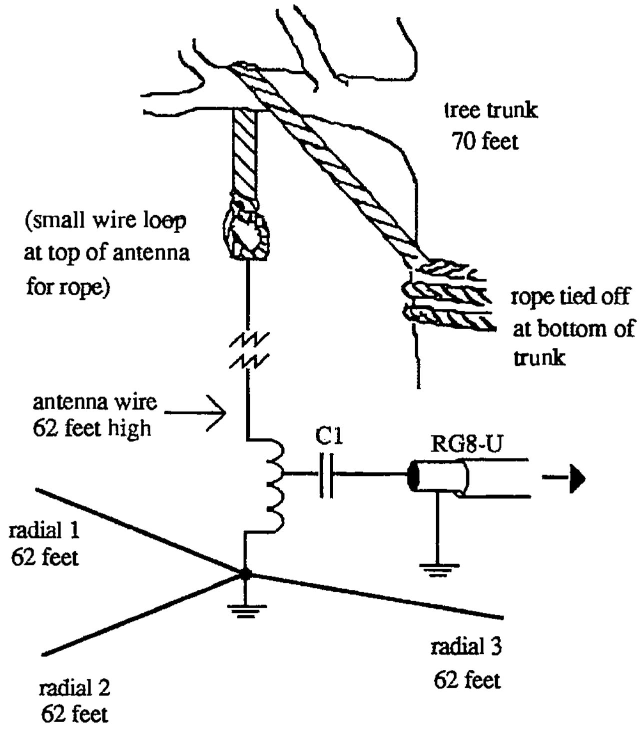

Fig. 1. Construction details.

Construction

Using a slingshot launch (with a 50-pound fishing line and a two-ounce lead sinker), I pulled up a 62-foot length of wire. I intentionally made it shorter than a quarter wave. This antenna needs a coil at the bottom to resonate it on 80m. The coil is inserted between the bottom of the vertical wire and the ground, as shown in **Fig. 1**.

The ground connection is a metal stake driven four feet into the earth near the bottom of the antenna. The antenna is always grounded for DC. Three 62-foot radials are laid on the ground. They can be buried or raised above the ground a few inches, whichever is more practical, but don't raise them very high (you will understand why very soon).

I used an old piece of coil stock (B&W #3022, and 16 microhenries, according to the label). The original coil was 14-gauge wire, eight turns per inch, one and three-quarters inches in diameter and four inches long. Four turns had broken off, so it was only 14 microhenries when I checked it on the inductance meter.

The bottom end of the coil was connected to the metal stake and the top end to the antenna wire, which was hanging down from a branch. Holding my dip meter next to the coil I found that the system resonated at 3.75 MHz.

Tuning

Matching this to the coaxial feedline was easier than I expected. Since the feed point is right at ground level, you can adjust the match until it is exactly what you want without raising and lowering the antenna for each adjustment.

Using a QRP setting with 5 watts output on my Century 21 rig and operating at 3.75 MHz, I connected the rig to the top end of the coil with a two-foot piece of 52-ohm coax through the SWR bridge. The shield of the cable and the ground lug on the Century 21 transmitter were both connected to ground. The SWR bridge was right at the transmitter output.

At first there was a high SWR. The coil at the base of the antenna required a capacitance to compensate for the inductance. I tried various sized surplus capacitors at the point where the feedline was attached to the coil, in series with the feedline.

The voltage is low at this point when the antenna is resonant. This means you can use any variable capacitor, even one with a low voltage rating, without worrying about it arcing between the plates. However, you will need a large amount of capacitance.

It took 600 pF to match the feedline to the antenna, and a tap down the coil eight turns from the top with the feedline connection. That gave four microhenries above the feed point (between the feed point and the bottom of the antenna wire) and 10 microhenries below the feed point (between the feed point and ground).

Each adjustment was recorded on paper, with its SWR, so that if I went too far in one direction, either in tapping on the coil or adding or subtracting capacitance, I could go back to where I had been.

The results

The tree branch was actually higher than the length of the wire, so I doubled over some of the fishing line. This gave me the safety of having the high RF voltage, at the top end of the antenna wire, a little lower than the tree limb supporting the antenna. Thus, no arcover was likely to occur from wire to wood if things got damp up there.

The actual SWR readings (checked at the feed point, at a point halfway between the antenna and the shack, where the remote coaxial switch is located, and at the shack connection) were: 1.6:1 at 4.0 MHz, 1.4:1 at 3.9 MHz, 1.1:1 at 3.8 MHz, 1.4:1 at 3.7 MHz, 1.9:1 at 3.6 MHz and 2.5:1 at 3.5 MHz.

Photo A. WØRKU's 80 meter vertical, with its "outhouse" enclosure.

The antenna works throughout the entire 80m band at full power, without the use of a tuner. Since I'm new to digital radio, I have recently been using it at 3604 kHz for the Midwestern RTTY net and some PACTOR contacts between 3600 and 3620 kHz, with excellent results.

Its performance on the DX portion of 80m (3690-3700 kHz) is excellent. The best DX contact was Croatia on 3694 kHz. Some of my contacts say "strong signal," without my asking for a report.

It's also excellent for rag-chewing on 75m. The Breakfast Club net control on 3973 kHz gives me good signal reports, even when he can't hear some others.

To keep moisture and dirt out of the coil and capacitor network, I constructed a little cedar box (see Photo A). The roof is sloped for water runoff, and it looks like a little "outhouse" for squirrels. I haven't cut out the crescent moon on the front door yet, but I did put a lock on the door! 73

73 Review

Now You See It, Now You Don't

You won't get stuck with this TapeTenna antenna kit.

Marshall G. Emm AAØXI/VK5FN
2460 S. Moline Way
Aurora CO 80014

I'm not an old-timer, precisely, but I fondly remember when the letters "CCR" stood for "Credence Clearwater Revival," and not "Conditions, Covenants, and Restrictions." Nowadays, PRB-1 notwithstanding, more than half of us live in places where they threaten to take you to court if you put up something that even looks like an antenna. Since we hams are inventive by nature, there have been all kinds of solutions to this problem, usually involving an attempt to make an antenna look like something else. HAMCO's TapeTenna kits make it possible to build real antennas, and make them disappear.

We're also intelligent consumers. Lemon products don't survive long enough to get reviewed, so I expected TapeTenna to work in accordance with its advertising promises. I was surprised, though, by the extent to which it exceeded its claims and the amazing applications I have found for the material in and around my shack.

TapeTenna secrets

The first secret to the TapeTenna kit is of course the tape itself, a highly conductive self-adhesive copper foil. The kit includes an instruction manual, connectors, and a generous amount of the tape—two rolls, for a total of 216 feet, so you will have enough for an 80m dipole and several other antennas. TapeTenna tape is pure copper, half an inch wide by about 3+ mils (.0035") thick, with a high-tech adhesive that will stick to just about anything, including bare masonry. The basic idea is that you use it just like wire except that you stick it onto things—walls, windows, roofs, chimneys—rather than hanging it between supports. And the tape is paintable: Once you've stuck the tape onto the wall of your apartment, for example, you can paint over it and it will literally disappear. The adhesive is conductive, so you can make connections simply by sticking one piece of tape to another. And since it is pure copper, it solders like a dream.

The second secret is the comprehensive instruction manual, which includes designs and specification for lots of different antennas, and a lot of basic antenna theory which will give you the basis for experimentation. There are diagrams to clarify the instructions, and a beginner will be making effective stealthy antennas in no time. In fact there is so much useful information about antenna design and construction that it wouldn't be going too far to describe the TapeTenna manual as a concise antenna handbook.

"It's an idea that seems so obvious you have to wonder why it hasn't been done before."

The third secret is the huge range of non-antenna uses you can find for the tape. The manual gives some indication of this, with coils wound on PVC pipe, open "wire" feedlines, etc., but it seemed for a while that I was finding a new use for it every five minutes. For example, I had an RF shielding problem with a device in a steel box. Running TapeTenna tape around the inside of the box fixed the problem. And in the process of removing a circuit board component, I pulled a little piece of track off the board—fixed it in about 30 seconds with a tiny TapeTenna "band-aid."

Traditional antenna designs

I built a couple of the antennas described in the manual, and they worked perfectly—it really is just a matter of using the tape instead of wire. There are some limitations, of course. I suspect that at UHF and above the width of the tape might become a factor in calculations, and of course you do need something to stick it onto.

Photo A. The TapeTenna.

My first project was a 2m J-pole which is stuck to the side of my chimney. I was expecting a bit of directionality due to the closeness of the chimney, but it appears to be "radio transparent." I also built a "roll-up" J-pole for use with my HT when traveling. It's a six-foot strip of vinyl with the antenna stuck onto it, and a connector at the bottom end. The whole antenna rolls up into a cylinder measuring about an inch in diameter by five inches long. I can hang it up near a window in a hotel room in about 10 seconds flat. J-poles are great 2m antennas and it's no surprise that HAMCO now offers a separate "Tape J" kit.

The other tape antenna I built was a 20m dipole which is stuck to the ridge of my roof. Due to stray capacitance (induced by nails in the roof, impurities in the shingles, etc.), it will be necessary to adjust the length of a dipole as compared with the free space calculations, but adjustment is a snap—you shorten it by cutting with a utility knife. If you need to lengthen it, you're in for a pleasant surprise if you've ever had to splice wire—with TapeTenna you just stick another bit onto the end!

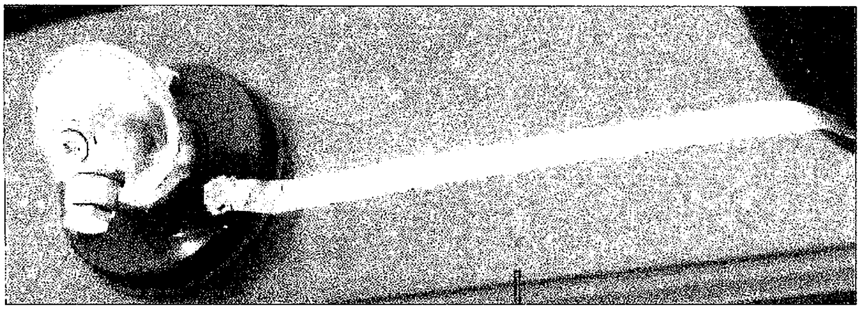

Photo B. TapeTenna mount on a plastic van. TapeTenna copper tape provides the ground.

Going mobile

I have a particular problem with mobile antennas—my vehicle is a Chevy Lumina APV. "APV" is supposed to mean "All Purpose Vehicle" but it also stands for "All Plastic Vehicle." The body is made entirely out of composite materials. Nothing even resembling a ground plane for a radio antenna. TapeTenna to the rescue! For years I put up with a poorly performing quarter-wave vertical for 2m. It was mounted on one of the side windows using a "trunk lid mount" and the addition of three copper tape radials made a substantial difference in its performance. In order to reduce the "visual impact," I cut the tape in thirds lengthwise and applied one of the three radials more or less horizontally on the top of the van, and the other two running down the window at 45 degrees from the mount.

Another option, described in the manual, is an inverted V stuck onto the back window. And I've calculated that I could stick a 10-element beam on the roof, with a gamma match made out of, well... tape!

2m mobile antennas are easy. In contrast, HF mobile looked like it was going to be impossible. All HF mobile antenna designs assume that there is a lot of metal in close proximity to the base of the antenna. You can argue all day over whether the car body is acting as an RF ground, an elevated ground plane, a counterpoise, or some combination of the above. Doesn't much matter if you don't have any metal to start with. I found very quickly that in my plastic van, the chassis does *not* do the job. Period. What few metal components there are appear to be electrically isolated, and in fact all electrical components are grounded by wire back to the battery rather than through the body or chassis. Solution? I ran a continuous strip of TapeTenna material around the bottom outer edge of the van, following the contours of the wheel wells and bumpers, and connected it to the "grounded" bolts of the antenna mount. SWR immediately dropped from 3:1 to 1.2:1 on 10, 20, 30 and 40m, the bands for which I had resonators. I doubt this is a permanent solution because the tape is exposed to water, dirt, and other road hazards, but it has held up for several thousand miles and, when it becomes necessary, it will be simple enough to replace it with a similar loop inside the van.

A thousand uses?

If there is ever a ham radio Scheherazade, she could entertain the Sultan with a thousand and one stories about using TapeTenna. It's an idea that seems so obvious you have to wonder why it hasn't been done before. Well, some of it *has* been done before, with burglar alarm tape, or copper foil tapes designed for other purposes, like stained glass work (extremely expensive and with questionable adhesives). These alternatives are often less than a third of the thickness of the TapeTenna material and correspondingly less likely to withstand mechanical stresses. In fact, burglar alarm tape is *designed* to break! It's hard to solder aluminum, and the copper tapes are expensive, with adhesives of debatable durability. TapeTenna brings it all together with a very specialized tape material at a reasonable price, with a wealth of good ideas and instructions.

Availability

TapeTenna kits are available ($64 postpaid, Tape-J kit $23 postpaid) by mail order *only* from: HAMCO, P.O. Box 25, Woodland Park, CO 80866.

NEVER SAY DIE

Continued from page 27

article for possible publication in *73* to help newcomers to the field? They need to know the suppliers, the publications, have a list of recommended books, how distribution works, what frequencies and services are available and their average costs ... things like that.

If we can get a series of articles to help *73* readers come up to speed on business communications services, that'll help a bunch of hams build some spare-time income, and maybe be able to take their new consulting businesses full-time as entrepreneurs. So what's out there in BBS software? In security products and services? In video conferencing? Satellite services?

Or are you happy with your old ham gear and not enough money even to buy a subscription to *73*? Tsk. The money is out there in great big gobs, you just have to make a little effort to grab it. And that means turning off the ball games and doing some homework instead. Get off that couch, put down that can of beer, brush off the pretzel crumbs, and get cracking. I don't care if you're 20 or 70, you can learn new things and it'll be some of the best fun you've ever had. Heck, I'm 74 now and I'm tackling a whole new branch of physics ... one which not even the best scientists in the world understand yet ... cold fusion. Now *that's* exciting.

I'd love to know more about communications, so I'll be reading any articles submitted for my own edification as well as yours. That means they've got to be simple enough so I can, duh, understand them.

Cover Contest

An old ham friend of mine, who is probably libido-challenged, suggested that I run a cover photo contest for hams with gorgeous wives, daughters, or granddaughters clad in swimsuits doing ham things. Well, it works for *Sports Illustrated*, so what the hell! Keep in mind that a vertical format fits the cover best, even if the young lady prefers more horizontal activities. Was it Cleopatra who said, "I'm not prone to argue?" If your model has a call, so much the better. Hey, I mean a ham call, not a pager number. Send her up your tower, or maybe a hilltop with an HT—heck, use your imagination.

I can make do with 35mm, but a larger negative will make a sharper picture if you can borrow a good camera. Let's see what you can do! Watch out, *Playboy*.

"Anyone Can Talk"

In editing an article on keeping CW alive I can across that observation by the author. Well, yes. But in my 48 years of on-the-air experience, very few people have bothered to learn how to talk interestingly to strangers. Somewhere around 90% of the contacts I've made could have been made with a recording, at least until I've managed to blast

Morse's Code

How the Tech's terror was invented.

Beth Price KC8ALW
913 Middlebury Drive North
Worthington OH 43085

Samuel Finley Breese Morse tried everything. In his 81 years of life he was an artist, inventor, photographer, teacher, and he even ran for Congress and for Mayor of New York City. Even so, he was poor until fairly late in life. Morse was a fascinating man—a real genius. So how did he get the idea for the telegraph? For Morse code?

He was born in 1791 in Charlestown, Massachusetts, the oldest of the three children (out of 11) who survived. His father, Jedidiah, was a minister, the author of the first book of American geography, and a friend of George Washington. His mother, Elizabeth, had a grandfather who was president of Princeton College.

As part of a family tradition, he went off to Yale College at 14, where he was very bored. Only the electricity classes held his interest. In class he even made his own batteries. However, he had always wanted to be a painter, so when he graduated in 1810 he went to study art in Europe, funded by his not very enthusiastic parents. He developed into a very good painter and several of his works were accepted by the Royal Academy in London. In 1832 he ran out of money and headed home.

On the voyage home, he got to talking with some of the other passengers about sending messages by electricity through wires. This excited him so much that he spent the rest of the trip making notes and drawing diagrams for an invention he called the "telegraph."

Once home, since no one wanted paintings of landscapes or mythical heroes such as he had painted in Europe, he had to resort to painting portraits. While traveling from town to town he met and married Lucretia Walker. They soon had three children: Susan, Charles, and Finley. Supporting his family while working on his invention was difficult, so he invented a water pump for firemen and a marble cutter. He even turned to teaching painting and photography. One of his photography students was Mathew Brady, who would later become famous for his Civil War photographs. Later on, Morse even painted President Monroe, the entire Congress, and Marquis de Lafayette, a French general. Even so, most of his money went into developing the telegraph.

However, before the telegraph was finished, Lucretia died. Morse, heartbroken, left his sons with his brothers and his daughter with Lucretia's sister and went back to Europe to paint.

He returned to the United States to market his telegraph, demonstrating it in 1837 to a group of influential men. Only one of them, Alfred Vail, was interested in financing it. Vail agreed to become a quarter partner with Morse, to help him build a sturdier model. Soon, Morse took on two other partners, Leonard D. Gale, and Joseph Henry, a scientist, to help him.

"The telegraph was invented at a time when most people didn't know what electricity was."

The telegraph

It was a simple design, but it was his own. He made his own wire by soldering little pieces together and wrapping them with cotton thread for insulation. The invention itself was a long wooden strip with notches filled with metal on top, which was called a port-rule. The port-rule was underneath some electrical contacts. When it was drawn underneath them, it caused the contacts to open and close, opening and closing an electrical circuit. Morse had 1,700 feet of wire strung around the room where he experimented, ending at a receiving site, where it recorded a dot-and-dash-type message on a strip of moving paper tape. The tape was drawn by a clocking device. A pen directed by an electromagnet wrote the dots and dashes. However, the port-rule was slow, a problem which led to the invention of the faster-operating code keyer.

In 1842, Morse and his partners set up another demonstration, this time with several miles of wire stretched underwater from Battery Island to Governors Island in New York. Just before the demonstration the wire got caught in a ship's anchor, and when the anchor was raised, the crew cut the wire. Morse's invention was thought to be a hoax.

Finally, Morse got to show his telegraph and code to the United States government in 1844. The wire was strung from Washington D.C. to Baltimore, over 37 miles of land. He tapped out his now-famous message, "What hath God wrought?"

From then on life was easy for Morse—money was no longer a problem. In 1848, Morse was married again, to Sarah Griswold. Together they had four children, and Morse bought a mansion near Poughkeepsie, New York. With spare time on his

hands, Morse ran for Mayor of New York City and for Congress (he lost both times).

Meanwhile, the telegraph's importance grew. Within 10 years of Morse's first message, 23,000 miles of wire were laid, and thousands more were laid each year. By the time of his death in 1872, the lines had stretched from California to India. Messages that would have taken two to four weeks to send by mail now took less than a day by telegraph. By the beginning of the Civil War the telegraph had become the mainstay of worldwide communication—though it had been invented at a time when most people didn't know what electricity was. Morse helped to start the way of life we know now.

Morse code

From the time Morse first got the idea for the telegraph to the time of its making, he also worked on codes. When he was working on the port-rule telegraph he even had a code book. In it, there were certain codes for different names, dates, and places. However, this really limited the contents of the message, and the code book was not practical.

Then Morse came up with a code that is now called American Morse code. This is a code consisting of dots and dashes (said as "dits" and "dahs") which stand for letters of the alphabet, numbers, and punctuation. Although American Morse is not used today, the code we do use has the same concept. Today, we use International Morse code. It's different from American Morse because there are differences in the code for letters. American Morse has spaces in between some elements of the code, and some dahs are longer than the normal one. In International, the dahs stay the same length. A dah is three times the length of a dit. The space between the elements of the code is the length of a dit. The space between letters is three times the length of a dit, and a space between a word is seven times the length of a dit.

Morse made the most frequently used letters the shortest and easiest to send. The letter E is the most commonly used letter in the English language, and it is a single dit. Letters like Q and Z are longer and more difficult to send. To figure out the frequency of the letters, Morse went to a local printer and looked through the print box. He wrote down how many pieces of type were on hand for the printer to use for each letter of the alphabet. However, most of the code came straight from Morse's head. He claimed that the hardest part of his invention was designing the code. 73

Note: Beth's mother, father, and sister are all hams. She wrote this as a school project and her father, Mike, thought it was something the local ham club might like to print in their newsletter. He was right, so this is a reprint from the *Radiogram*.

Top-Loaded Vertical for 2 Meters

A small antenna with capital T performance.

Thomas M. Hart AD1B
54 Hermaine Ave.
Dedham MA 02026

Not long ago, I purchased a book by John Devoldere ON4UN titled *Antennas and Techniques for Low Band DXing* (1994, ARRL Publications). I was amazed at the variety of antennas used on the 160, 80, and 40 meter bands in the endless quest for a really BIG signal. One popular antenna design on these bands is a top-loaded or "T" antenna.

"If you are vertically challenged and need to compromise on physical dimensions, this antenna might be the solution."

Refer to **Fig. 1** for the basic shape of top-loaded antennas as well as the dimensions that I am using in my scaled-down version. In general, this class of device is characterized as a short vertical with top-wire loading. The difference between the actual height of the antenna and a natural quarter wavelength is approximately one-half the length of the top section. Due to real life variations in terrain, grounds, radials, construction materials, and all of the rest, a fair amount of cutting and pruning is usually necessary.

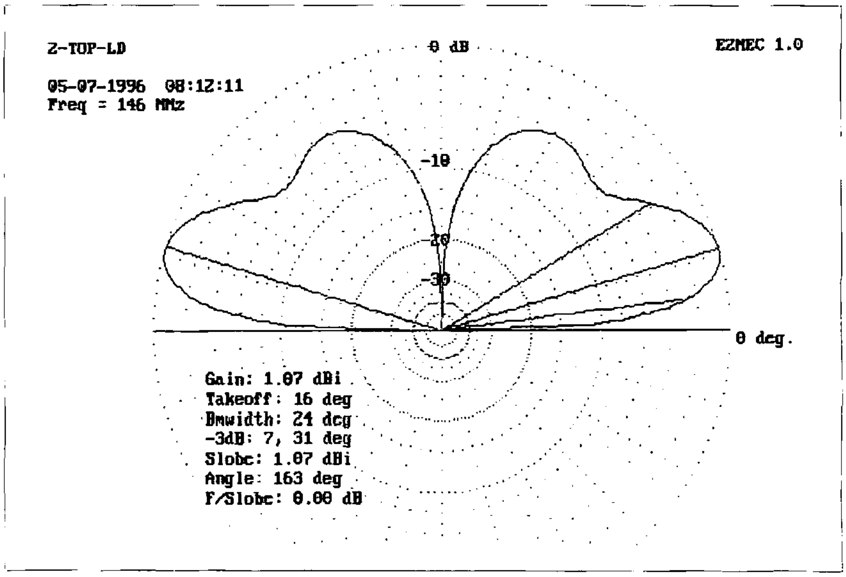

Fig 2. *Vertical-plane radiation pattern for the top-loaded vertical.*

My need for a 160 meter vertical is not too critical at the moment, but I really did need some help on the 2 meter band in order to work local packet stations. I am particularly interested in using the 145.69 contest/DX packet system at the QTH of Bruce WA1G. The horizontally polarized dipole on the top of my bookcase was not doing the job. Whatever replacement I developed had to fit into a 16-inch vertical space, which eliminated a quarter-wave ground plane.

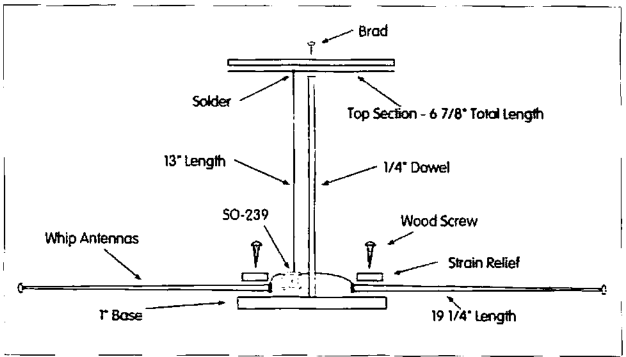

Fig. 1. *The 2 meter top-loaded vertical with 2 radials.*

Returning to the low band metaphor, I decided to try a top-loaded antenna with a 13-inch vertical section (this would be 0.667 times the quarter-wave dimension). I built a half-wave dipole for 2 meters, starting with insulated hookup wire elements cut to an initial length of 21 inches. Using a 2 meter SWR meter, I carefully pruned until I had an SWR of 1:1. This provided the physical dimensions for a quarter wave length. The end of the dipole attached to the center of the coax feed line was then cut to a length of 13 inches and a

top section soldered to the far end (at the center of the top section). The next step was to carefully trim the top loading section in order to return to an SWR of 1:1 using the previously tuned remaining dipole element as the other half of the antenna. The final step was to build a wooden frame to hold the newly tuned vertical element, add two horizontal radial counterpoises (collapsible whip antennas) and make the final adjustments. The final tweak was needed to restore the SWR to 1:1; this involved nothing more than setting the length of the two radials.

How does it work? I am quite satisfied and have been able to do my packeteering very nicely. The antenna was easy to build and cost only pennies. The accompanying antenna pattern generated by the EZNEC software package shows that the antenna is omnidirectional and has a low take-off angle, both very desirable for my application. The top loading avoids the mechanical and electrical problems associated with building and using coils at the base or midpoint of a short antenna. The use of collapsible whip antennas as radials simplifies the construction as well as the tuning, and provides rigid elements. If you are vertically challenged and need to compromise on physical dimensions, this antenna might be the solution. 73

Manufacturers if you would like to have your new products reviewed in 73, please call Fran at 800-274-7373 for details.

NEVER SAY DIE

Continued from page 33

the other chap out of his rut—if you call the Grand Canyon a rut.

Being good at anything takes work and practice. Even sex. And being good at talking on the air is no different. I have never found a skill of any value that didn't take a lot of work and practice. Flying, horseback riding, scuba diving, skiing, and so on are not God-given talents, they're skills, and so is the "gift of gab." It's a hard-won and very valuable "gift."

Let's be honest, oh great communicator, have you ever tape-recorded a few of your contacts and then listened to them critically later? Of course you haven't, or else you'd have done something about the situation a long time ago. "The rig here is"—oh, good grief!

Pointers

When you read the newspapers and magazines, look for interesting items and cut them out. Read 'em over a couple of times so you'll be able to talk about them. The "Only In America" series in Seligman's *Fortune* "Keeping Up" column has great fodder. "Hey, did you read about ... ?"

Unless you've done almost nothing to take advantage of the opportunities amateur radio has provided you for adventure, you should have at least a few interesting stories to tell. Make notes and post 'em where you can see 'em when you're operating. Remember, when you're talking with someone you owe it to them to keep your attention focused on what they're saying, so you're not going to have a lot of time to organize your thoughts. Having some reminders posted helps.

It's a little late now, but you might get your grandchildren started in the right direction by suggesting that they start keeping a collection of the jokes they've heard—otherwise they're going to forget 99+% of 'em. No good salesman is without a solid opening joke, and you shouldn't be either. Hey, did I ever tell you about the RPI grad who was in line for the guillotine when the contraption stopped working? "Hmm, maybe if you tighten that little screw up there."

I'm reminded of the RPI physicist who called in while I was being interviewed by Art Bell on his Coast-to-Coast radio show back in May. I'd been explaining about cold fusion developments and he called in to tell me that cold fusion was impossible because there were no gamma rays being detected. I tried to explain to him that when experimental results conflict with theory, it is theory which should give way. No sale. The listeners loved it.

The most important aspect in making your contacts interesting is to listen and ask questions. The more you get the other chap talking about himself, the more interesting the contact is going to be for him. If you listen to me on the air I'll give you clues on things to ask about, but I'm going to be asking you a lot of questions. Like what kind of work did you do before you retired? Are you doing anything now that takes advantage of the skills you built while you were working? Stuff like that. And if I find any area of mutual interest, we'll have a memorable contact.

Yes, I had fun working new countries when I first got a big antenna up in the air and could work anything I could hear—and could hear everything. But now I'm into quality instead of quantity. I haven't counted how many countries I've worked in years. Sure, I used to go through a country list and check off all those I'd worked. Now I just check off those I've visited.

Sometimes I don't get anywhere getting the other guy to talk, no matter how I try. A

The Magical Audio Filter Revisited

Updating a dandy little receiver helper.

Jim Pepper W6QIF
44 El Camino Moraga
Orinda CA 94563

Almost any receiver can be improved by the addition of an outboard audio filter, whether for CW or phone reception. A good filter can help you hear the stuff you want to, and get rid of the garbage that's interfering.

An article of mine in the November 1983 issue of *73* (Jim Pepper W6QIF, "The Magical Audio Filter," page 14) resulted from my looking for a null and peaking circuit. I found a design in the *National Semiconductor Linear Applications Manual* that provided a nulling circuit (January 1972, pages AN31-14). It turned out that it also had, as an integral part of the design, a peaking circuit. I modified their design to use a variable resistor rather than a capacitor to vary the null frequency.

Several readers wrote to say that the circuit worked well, but they had some trouble with the circuit oscillating. This was primarily due to the output stage, an LM-383. Since then I've made some improvements, so the circuit now produces a filter with an attenuation of almost 50 dB at 2 kHz, as compared to the original 20 dB. Now I'm using an LM-386,

"It's an easy weekend project."

which gives a very stable, though reduced, output. To get the increased selectivity I added one more stage to the circuit. I used a Max-295, an

***Photo A.** Magical Filter II, front view.*

8th-order, low-pass switched-capacitor audio filter (SCAF), which gives approximately -50 dB per octave, as compared to -6 dB for a single-pole filter.

There are two positions for the filter: one rolling off at approximately 1 kHz for CW, and a second at 2.5 kHz for phone. The two positions are front-panel selectable by NB/WB switch (S3). See **Figs. 1A** and **1B** for the response curves. The response curves were derived from voltages measured at the output of the LM-386 and compared to the voltage from an audio oscillator output. Since the output circuit also contributes to the rolloff, I chose to set the volume pot at a point where the output voltage of the LM-386 was equal to the voltage from the audio oscillator (the LM-386 has a gain of 20 dB.). The reference voltage was also chosen when the frequency was 1 kHz.

The null circuit is the same as my original design. It is used to eliminate steady carriers, but is a little difficult

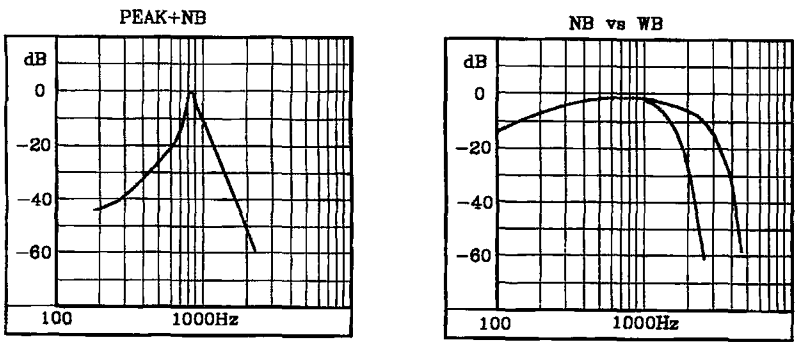

***Fig. 1.** Response curves for the two filter positions. **A)** Rolling off at approximately 1 kHz for CW. **B)** At 2.5 kHz for phone.*

to use on CW signals because it is so sharp and provides about 20 dB of attenuation.

The peaking circuit is still maintained and the peak frequency is front-panel adjustable, varying from 500 Hz to 1500 Hz, and centered around 800 Hz. It provides about 20 dB of peaking. To prevent my having to jump to the volume control when it is switched in, I put in a fixed attenuator to drop the incoming signal by 20 dB. Thus, when the receiver is tuned off to the side of the signal, the background noise is also reduced by this. factor. The peaking circuit can be turned off for phone reception by closing S1.

This outboard filter circuit is designed to be plugged into the headphone output of the receiver, so no additional internal wiring changes are necessary. The LM-386 provides plenty of output to drive a speaker. The input to the unit is controlled by the receiver volume control and is set to prevent overloading the filter circuits and output stage. An additional gain control (audio pot) is available on the front panel to control the output level of the unit. The control is designed to be either AC-operated or from a 9 volt battery.

The unit is made on a PC board (available from FAR Circuits, 18N640 Field Court, Dundee IL 60118) and housed in a 4" x 3-1/4" x 2-3/16" metal enclosure. The parts location is silkscreened on the PC board to aid in construction. There is only a minimum of wiring necessary, which includes wiring the front panel switches. The pots and transformers are mounted on the PC board.

The hole diameter for the switches on the panels is 1/4", and 5/16" for the pots. As an aid to drilling, I found that a piece of 2x4 lumber inserted in the chassis makes an excellent backing for drilling.

Mount all PC board components and wire the front panel switches and speaker jack before putting the board into the box. It's a good idea to check the unit's operation before inserting it in the box. The AC wiring and the wire for the speaker plug can be temporarily connected to the PC board at this time. (Note: Be sure that the body of the male phone plug goes to the ground on the board. The tip goes to the input point.)

To help support the PC board if the transformer is used, use 6-32 screws 3/8" long, mounted as indicated, with the head on the top side of the PC board.

Preliminary testing

Before plugging in the ICs, it is best to check the various voltages on the board. Plug in the AC cord and turn on the AC SW. If the unit is still in one piece you can check the voltages at the regulators. Also check the voltage on pin 7 of the Max-295 (IC3); it should read no greater than 10.5 volts. The SCAF is rated 11V max. If the voltages are correct, turn off the power and insert the ICs. All number 1 pins of the ICs go to the rear of the board.

Connect the input plug to the receiver output and plug in an external speaker or headphones. Turn on the receiver and filter. Set the filter audio gain to about one-third on. Place the filter in the bypass position (S2 in FILTER OUT). Turn up the receiver volume control to a good listening level with a CW station tuned in. If the signal is breaking up on peaks, the input is too high.

Set the PEAK switch (S1) to OFF or closed position and the bandwidth switch (S3) to WB. Tune the receiver to a fairly loud CW signal to your desired copying pitch. Switch (S2) the filter to the IN position. Turn the PEAK switch (S1) to ON, or open position, and adjust the PEAK control to give the loudest volume. There should be a pronounced increase in volume if the circuit is working correctly.

Next, tune the receiver off frequency from the CW station to about 1.5 kHz higher. Change the WB/NB switch (S3) to NB. You should note a change in the signal level. Switch out the peaking circuit and note the increase in background noise. Now rotate the NULL pot in a clockwise direction. At about the three-quarter position you will find that the signal reduces in volume. If all these tests work as expected, it's time to put it in the cabinet.

Copy the drawing for the front panel by placing it on a clear laminating material (available at stationery and variety stores), cutting it to size. Be sure the drawing is full-scale. I found that if I stuck the artwork on the panel with

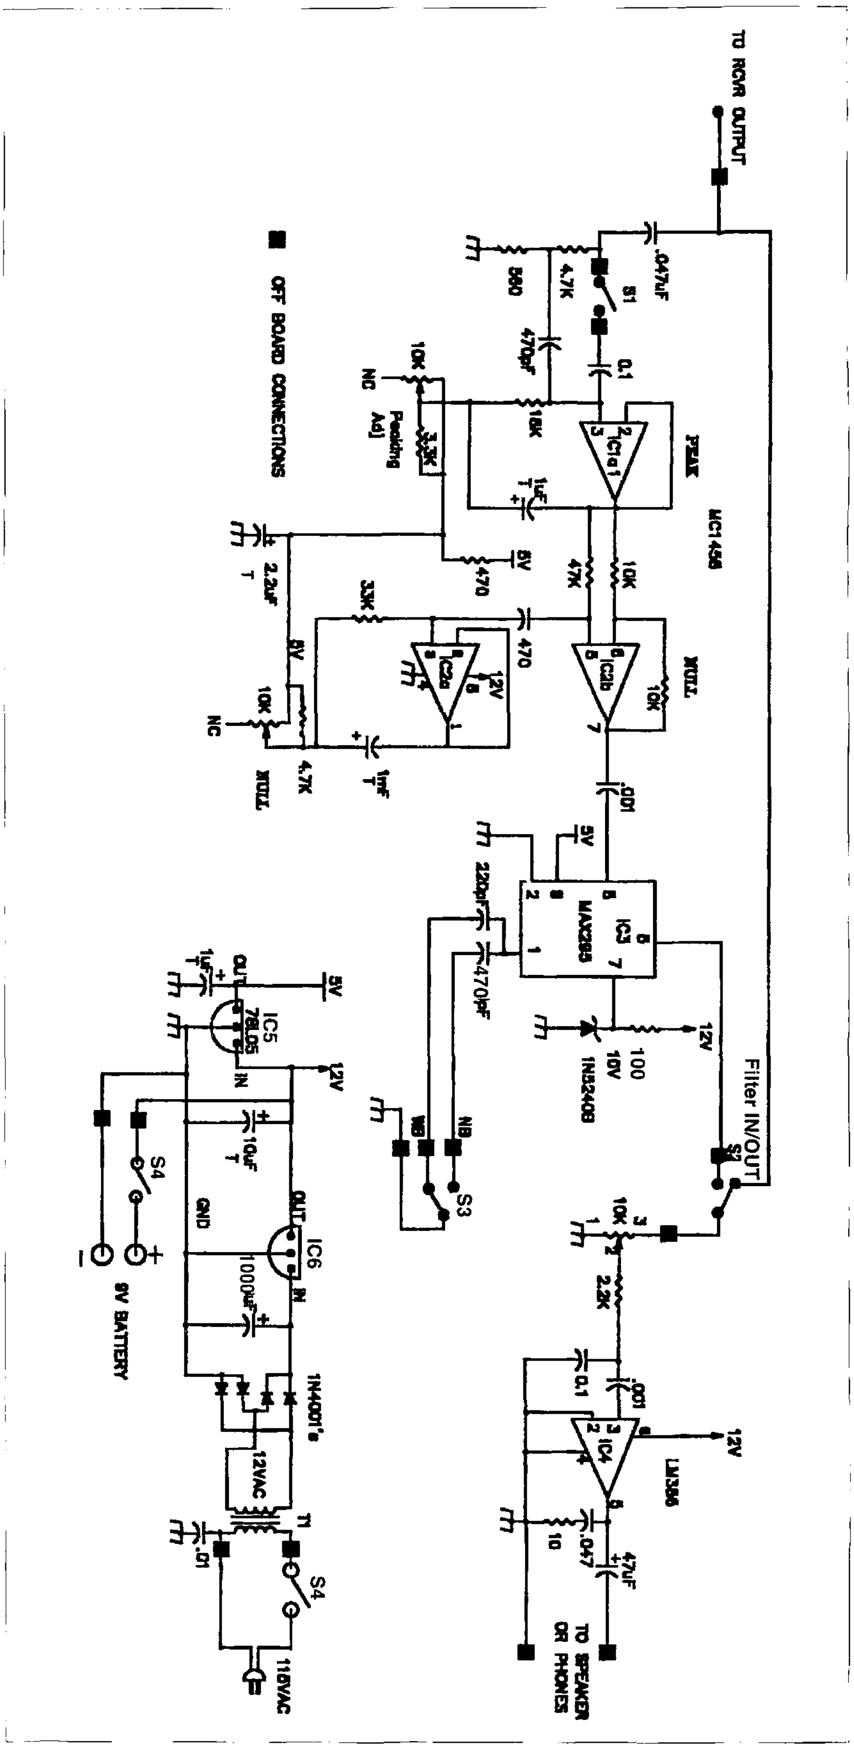

Fig. 2. Schematic for the Magical Filter II.

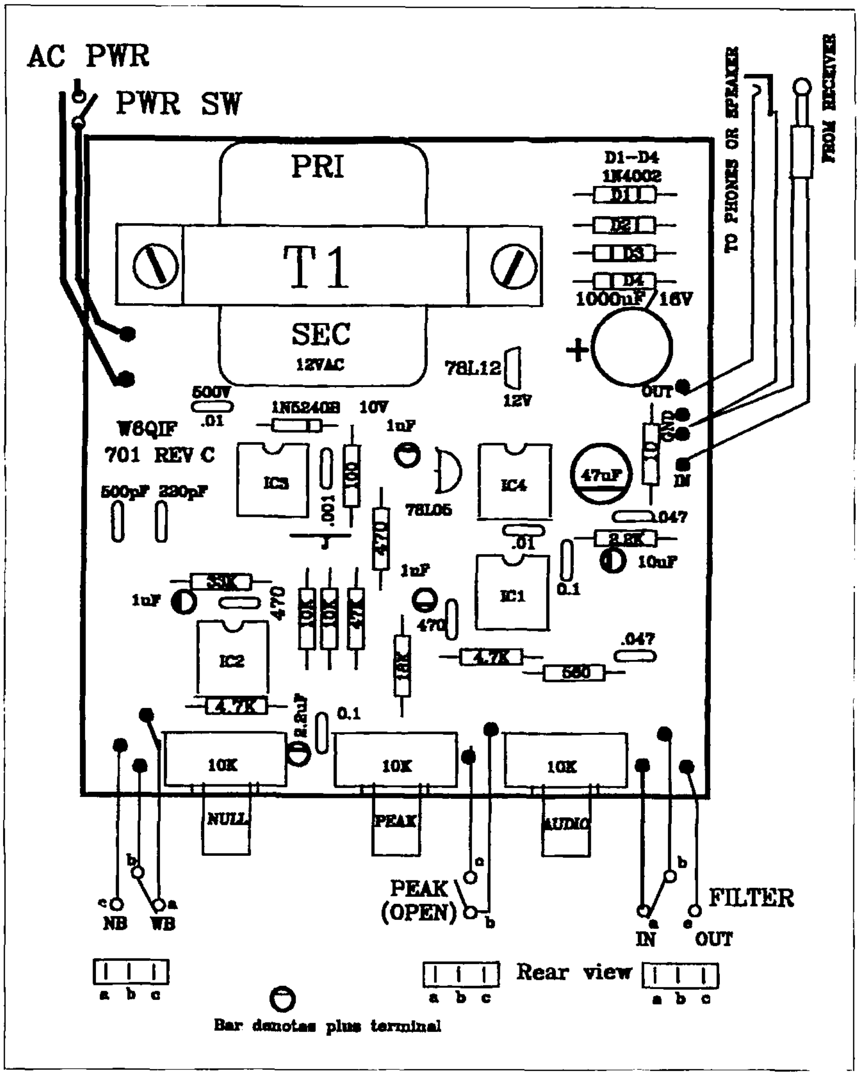

Fig. 3. Magical Filter II board parts placement diagram.

a thin coating of white carpenter's glue it was easy to cut out the holes for the pots and switches with a hobby knife.

Next, connect the AC wiring and speaker plug as shown on the assembly drawing. Prewire the two cables through the rear panel before you insert the PC board; this way the connectors can be left on the cables. Be careful that the AC switch terminals do not touch the transformer frame.

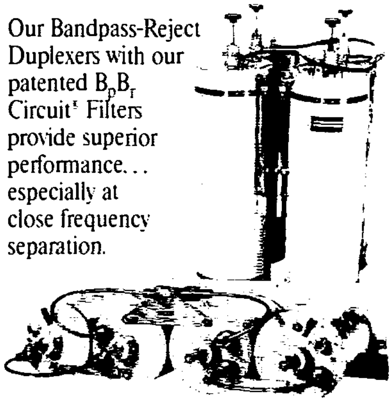
It will be necessary to place 1/8"-thick space washers on the three pot shafts to properly mount the PC board to the front panel. The PC board pots will slide into the front panel and nuts can be applied at this time. The front panel switches can also be mounted now. Be sure they are properly oriented to comply with the panel labeling. If not, they can always be rotated later on.

Battery operation

If you want to use the filter for portable operation you can replace the transformer with a 9V battery. The battery can be held in place by a wire soldered to the holes available for the primary and secondary leads to the solder pads of T1. Connect the battery *minus* lead to ground and the battery *plus* lead to ON/OFF switch S4. The **Parts List** indicates which parts can be left off. A worthwhile addition might be an LED to indicate when the battery power is on. If both types of operation are contemplated, an external connector for a battery can be used.

Conclusion

I have used this unit with my direct conversion receiver as well as with my FT-840, and have found it very useful.



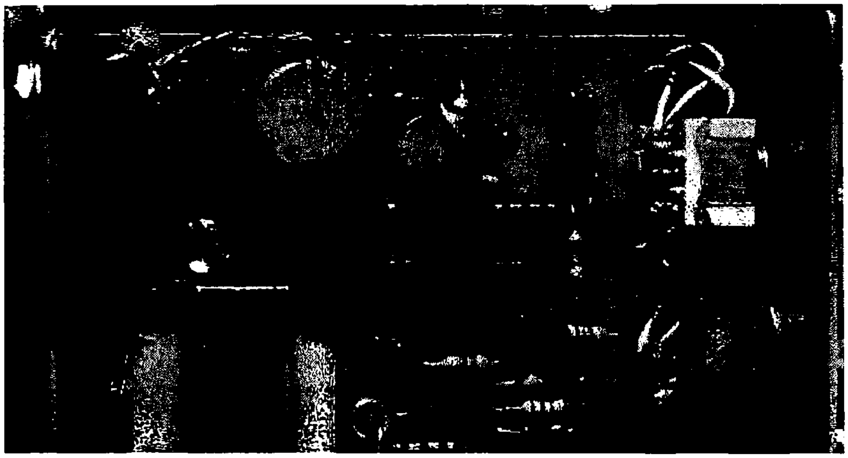


Photo B. Inside view.

My 840 does not have the CW filter, but this unit does a job that is almost as good. You might want to improve the NB position even more on your filter. This can be done by changing the 470 pF capacitor, which is connected between Pin 1 of IC3 and the NB position of S3, to 620 pF. This project is a way to improve any receiver's selectivity for a minimal cost, and it's an easy weekend project.

NEVER SAY DIE

Continued from page 37

chap the other day had been retired for years and the highlight of his day was going out to lunch with his wife. Other than that it was playing golf. Period. Sigh.

Of course if all you want to do is fill in year after year of signal reports in your log, that doesn't take anything but time. Yes, I did that for a while. Been there, done that. Ditto the 75m net where nothing of substance ever was discussed. Done that too. Well, it does give you a feeling of belonging to a group. But that was 50 years ago and W1KPL, W1MLJ, and W1IF are all long gone. They're all Silent Voices now. They smoked. Oh, W2MSV was fat, so he died young. Ditto W2MAM.

If you're short on interesting things to talk about, read a book! Read any one of the books I've reviewed in my past editorials, or those on my $5 list of books you're crazy if you don't read, and you'll be well armed to talk anyone's ear off. Hey, read the NASA book and drive everyone crazy about the Apollo shots all being bogus. They may think you're crazy to believe such obvious nonsense, but you'll be well armed if anyone actually wants to discuss facts. Most don't. But then Galileo couldn't get people to look through his telescope and Pasteur had the same problem with his microscope. Little tiny germs? Preposterous!

A Terrible Business

When Chuck Martin WA1KPS told me he was going into the ham radio business as a dealer I warned him not to do it. I explained that it was probably one of the worst businesses he could go into. Thus was Tufts Radio launched. Well, Chuck eventually found out for himself what he'd gotten into. His love of amateur radio was stronger than his sense of reality and overrode my warnings. Yes, he eventually went bankrupt.

In a recent editorial I pointed out that ham dealer margins are far below those of almost any other business. I cited a figure of 25% instead of the more normal retailer 50% minimum. Well, it didn't take long before a few ham dealers put me straight. I was wrong. Yes, Uncle Wayne mis-wrote. I was assured that the margins for ham dealers on most rigs is more like 7%. And out of that comes 2% for the credit card and 1% or so for freight costs. This is gross profit, not net. The dealer still has plenty of overhead that has to come out of the 4% he has left. Like the store rent, warehouse space, taxes, insurance, personnel (including health insurance), heat, light, water, building maintenance, advertising, telephone, copiers, computers, bookkeeping, office supplies, shipping materials, and so on. Having built a chain of computer software stores I know the drill on retailing.

Do I have an answer for this? No, I'm stumped. It's illegal for the dealers to get together and set prices so everyone can make a buck. And, as a consumer, I'm not about to pay more for something than I have to, so when one supplier has a lower price, that's where I buy. And I'm willing to forego some service to save money.

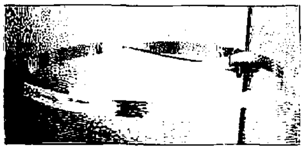
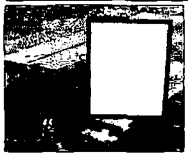
NEW PRODUCTS



Try On This Halo

The Homeowners' Association Gestapo giving you static about your antenna? Want to work real ionospheric skip DX on 6 meters? Here's a heavenly new item from Advanced Electronic Applications, Inc.

The HALO-6 will allow you to use your new multiband transceiver on 6 meters at the lowest possible cost. It comes as an easy-to-assemble kit—about 30 minutes to put it together—for $69! It's so flexible it can squeeze through attic openings and other tight spaces; you can even support the antenna with fishing line in your attic. The higher you mount the HALO-6, the higher performance you will realize. Minimum mounting height is six feet, great for mobile users and antenna-restricted operators. No matter how you mount the HALO-6, you'll benefit from its omnidirectional radiation pattern and its low angle of radiation. See your dealer or call AEA's 24-hour Literature Request Line at (800) 432-8873 for more information.



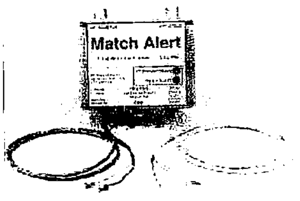
Ham-Panel 440

And now for something completely different: Ant-Panel Products has just come up with this intriguing antenna panel. Only 18 by 24 by 2 inches thick, the Ham-Panel 440 is a high-performance 90° beamwidth antenna with a VSWR less than 2:1 from 435 to 450 MHz.

Built in a sturdy enclosed frame, it can sit on the windowsill of your apartment, dorm room or office, and project your signal out of the building with a gain four times better than your old J-pole! The very high front-to-back ratio of the Ham-Panel 440 minimizes the effects of movement behind the antenna *and* RFI/TVI *and* computer noise in receivers. For more information or to purchase the Ham-Panel 440 ($119.95 plus shipping & handling, and tax if applicable), contact Ant-Panel Products, 530 East Fifth Avenue - Suite 12, Naperville IL 60563. Phone/FAX (630) 778-0793.

I Think They're Onto Me...

CCTV introduces the GBC Colorsentry Model CCD-835C color camera. OK, so you're not James Bond. It's still cool, this inconspicuous (smaller than a pack of cigarettes) 4mm lens color camera. If you ever want to photograph something discreetly, the CCD-835C has a 1/4" sensor, a resolution of 325 lines and a sensitivity of .5 lux. It comes complete with a 12VDC power module and 1/4-20 universal mounting. Other lenses are available—2.5mm wide angle, 6.5mm, 8mm and 12mm—making the CCD-835C camera perfect for any application where size and secrecy are important. For more information, contact CCTV Corp., 280 Huyler Street, South Hackensack NJ 07606; Phone (800) 221-2240 or (201) 495-9595; FAX (201) 489-0111.



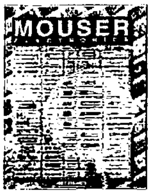
Check Your VSWR!

RF Applications has announced the availability of the Match Alert, designed to offer economical protection for HF transmitting systems. The microprocessor-based Match Alert monitors VSWR and provides a fast visual and electrical alarm if a preset VSWR level is exceeded (eight levels are switch-selectable, and an LED lets you know when RF is detected). The $129.95 you spend now for the Match Alert could save you a lot more, down the road.

For further information, write to: RF Applications, Inc., 9310 Little Mountain Road, Mentor OH 44060. Phone (800) 423-7252 (international (216) 974-1961); FAX (216) 974-9506. Internet http://www.rfapps.com, or E-mail to sales@rfapps.com.

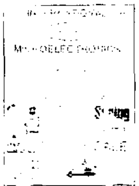
Free RF Neulink Catalog

RF Neulink has issued a new 28-page wireless telemetry catalog featuring crystal-controlled and synthesized wireless transceivers, transmitters and receivers—and the SkyLine RTU, a digital/analog data acquisition and control module. For your free copy, contact RF Industries, Neulink Division, 7610 Miramar Road, San Diego CA 92126. Telephone (800) 233-1728 or (619) 549-6340; FAX (619) 549-6345; or E-mail: 102061.2261 @compuserve.com.



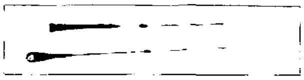
Mouser Releases New Catalog

Mouser's newly updated electronics component catalog offers more than 67,000 products from more than 125 manufacturers. An excellent guide for both buyers and engineers, this catalog provides complete specification drawings and guaranteed up-to-date prices. Mouser also provides same-day shipping on all stocked products. For a free catalog call (800) 992-9943; E-mail catalog@mouser .com; or visit Mouser's Web site at http://www.mouser.com. Nationwide sales: (800) 346-6873; FAX (817) 483-0931.



"You Want It? We Got It!"

Like to pore over small-print parts catalogs looking for the unusual and rare—and finding some real bargains? Get a copy of the International Microelectronics catalog! It's true—they've got it! They specialize in overstock, surplus, and discontinued electronic components, and this may just be the source you've been seeking so you can finish up that project. International Microelectronics, P.O. Box 170415, Arlington TX 76003. Phone (800) 999-0463; FAX (817) 473-0525.



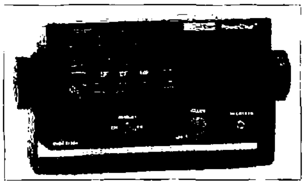
Two New Mobile Antennas from Premier

The 24-inch PNC-2 and its 37-inch sibling PNC-4 are now available from Premier Communications; they're both 2 meter/70 cm and deliver maximum signal gain for their size.

The PNC-2 has 2.1 dB gain on 2 meters, 3 dB gain on 70 cm, and handles 100 watts of power. It is set for near 1:1 SWR at 146.50 MHz and it's quite broadbanded; it also covers 130-165 MHz and 400-480 MHz and works great for receiving to 900 MHz.

The PNC-4 is a higher gain antenna optimized to 2 meter and 70 cm operation. It has 3 dB gain on 2 meters, 5.5 dB gain on 70 cm, handles 100 watts, and includes a tilt feature with locking base. Both models are pretuned and ready to install on mounts, and are sleekly designed in black chrome.

Both models have two-way base fittings that mate with UHF/SO-239 sockets or MNO/Motorola-type mounts. Premier carries mounting accessories for new installations. For more information, contact Premier Communications, 20277 Valley Blvd., Walnut CA 91789. Telephone (800) 666-2654; FAX (909) 869-5710.



Add On A PowerClear

About the size of a paperback book, the PowerClear from SGC can be used with any non-DSP transceiver (HF or VHF/UHF) or other audio device to improve audio quality and noise/interference reduction.

Features include flexible audio input/output connections—audio from transceiver, telephone, scanner, cassette recorder, etc. can benefit from ADP enhancement. The operator has full control of audio filters; push-buttons activate the notch filter as well as noise reduction and SNS. An internal amplifier with front-panel volume control allows room-filling audio even when driven from line-level sources. Lots more neat stuff, too, including all the LEDs to let you watch your tuning.

Contact your SGC dealer for price and availability. Call SGC (800) 259-7331 for the name of your nearest dealer.

STSPLUS, Version 9615

A satellite tracking program from RPV Astronomy.

Thomas M. Hart AD1B
54 Hermaine Ave.
Dedham MA 02026

Recently, I decided to take a look at software for tracking amateur radio satellites. My expectation was that I might be able to locate some of the more audible space vehicles and listen to their communications. I had visions of tracking the *Mir* space station or the NASA shuttle and hearing QSOs with ground stations. About the last thing I ever expected was to become a satellite chaser and actually make contacts.

A telephone call to the ARRL computer bulletin board system allowed me to download a variety of satellite programs and to try them out for free. This is a software distribution channel called "shareware." Try a program: if you like it, pay the registration fee (this is done on the honor system). If you are interested, the BBS is at (860) 594-0306 and uses standard telecommunications protocols from 1,200 to 28,800 baud.

After testing the various downloads, I decided that the STSPLUS software (released in April 1996) offered the features best for my needs. In fact, it has many neat features that I will probably never use, as well as all of the things that I really want. The program is offered by:

RPV Astronomy
David H. Ransom, Jr.
7130 Avenida Altisima
Rancho Palos Verdes CA
BBS: (310) 541-7299 (2,400-14,400 baud)
Cost: I contributed $20, the suggested amount.

Features

STSPLUS is a DOS program that will operate happily under Windows 3.1 (I have tested this; I have not tested it under Windows 95, but would expect it to work). Installed, the program requires 1.8 megabytes of hard disk space, including a 600 kilobyte manual that can be eliminated to save room. The program recommends an Intel (or compatible) 80386 or higher processor and works best with a math coprocessor. I am not aware of a Macintosh version.

The program setup is quite easy. Load the software into a suitable directory and set the latitude and longitude of primary and, if desired, secondary locations. Set the time, update the Keplerian elements (see below), and away you go on the great satellite chase! The program predicts, lists and shows a graphic of satellite passes by time, azimuth, elevation and range. All of this works on EGA, VGA, SVGA and LCD monitors. Mapping is available in a variety of formats and resolutions. Orthographic (spherical) or rectangular projections are available at the press of a single key. In the orthographic mode, the view may be changed from primary location to secondary location or to satellite-centered. Circles of visibility for the satellite or ground station are available. Zoom options run from 100% to 4,000%. Audible alarms (alerting you to times when the satellite is in range) are user-selectable. NASA ground station locations can be switched on and off the map as desired.

Time options include real time, simulated time and fast time. The simulated time and fast time options allow you to observe the satellite during a particular pass and gauge the possibility of contacting other desired locations. You can specify local or UST, as well as standard or daylight times.

Doppler shift is an important consideration in satellite work. As a satellite approaches, the apparent frequency increases; as it retreats, the apparent frequency decreases. As a practical matter, the ground-based transmission and satellite return will seldom be on the same frequency. Many amateurs use separate transmitters and receivers in full duplex to compensate. Others use software to estimate the up/down differences and compensate manually with a single transceiver. The final ploy is to simply send on the receive frequency and hope the other station is tuning up and down looking for contacts.

"Set the time, update the Keplerian elements, and away you go on the great satellite chase!"

One of the most important features of any program is the documentation. I have never seen a better and more complete manual for any other program. If you decide to print the "doc" file, load the printer and be prepared for a press run of 181 pages. I converted the file to Microsoft Word format and used a number 8 font with two columns per page in order to limit the size to a more modest 40 pages after some judicious editing.

The opening menu offers the following selections:

1. Convert Keplerian data to program file.
2. Read standard Keplerian file for program use.
3. Make pass predictions.
4. Tabulate pass predictions.
5. Set launch time/date.
6. Real time satellite data.
7. Select files/paths.
8. Set time and date.
9. Jump to DOS shell.
10. Set options.
11. Run the program.

How about the bottom line? I give STSPLUS software an "A+" without qualification. It's rare to find a program without those foibles and incongruities that make computer usage a frustrating experience. The graphics are perfectly suitable, menus are intuitive and printer output has clear and concise formatting. After two months of testing, I've found the predictions accurate, and haven't found any problems.

Computer systems do not need to be the latest Pentium running at 200 MHz. A more modest computer can produce the pass predictions in due course. The data can be printed and used to determine when the target is in range.

Footprints are the circles on the ground in line of sight with the satellite. These represent the area covered by the satellite signal at any given time.

Length of pass ranges according to the type of satellite and angles of acquisition. I've been tracking a Low Earth Object (LEO), namely the RS-12 satellite because this operates on Mode K. I have HF gear suitable for satellite work, but no VHF or UHF equipment. I have found passes to range from three to 18 minutes. When the satellite is in range, you have to work fast. The experience is similar to contesting, especially if you wish to make multiple contacts. When the Phase 3-D satellite goes up (next year, possibly), I may be in a position to access a high orbit bird that remains in sight for extended periods.

"I've had the chance to meet a new group of hams from Costa Rica to Scotland and make contacts with them in their homes, cars and campsites."

Approximately 250 SSB and CW contacts have provided 35 confirmed states and several countries. What's better, I've had the chance to meet a new group of hams from Costa Rica to Scotland and make contacts with them in their homes, cars and campsites.

Some info and tips

A few observations on satellite operations may help those who have never used them in the past:

Keplerian elements are factors used to compute the location of satellites. This data is available from the ARRL, AMSAT, the RPV Astronomy BBS (above) and many other sources.

Equipment can be quite simple. I am using Mode K, which is a 15 meter uplink and a 10 meter downlink. A simple transceiver with dual VFOs (a Kenwood 430 in my case) and a modest antenna (G5RV at my house) are all that is needed.

Operational aids come in many forms. I have found that a map of the RS-12 satellite footprint centered on my location is very helpful. My footprint is simply a photocopy of a map of North America trimmed to the appropriate size and marked with 360 degree points. After running STSPLUS predictions, I draw a line tracing the starting and ending points of each pass in order to have a sense of where the bird is at any point in time. I am able to visualize the path to various targets this way without using the computer. The size of any satellite footprint is provided by the STSPLUS program when in operational mode.

Further information on satellites is available from many sources. Numerous books on amateur and weather satellites are in print. Amateur radio periodicals print monthly updates on satellite operations. Finally, AMSAT promotes all aspects of this fascinating activity.

Ham Television

Bill Brown WB8ELK
139 Angela Dr. Apt. B
Madison AL 35738
bbrown@hiwaay.net

Early in the morning of August 24th, hams, students and lots of vehicles laden with ham equipment began to arrive at a small field next to Purdue University in Lafayette, Indiana. No, this wasn't a delayed Field Day exercise. It was another in a series of WindTrax balloon launches.

The WindTrax program

Back in July of 1988, Bob McAuliffe W9PRD, Bill Brown WB8ELK and Chuck Crist WB9IHS launched Indiana's first high altitude balloon carrying ATV and 2m equipment. The spectacular results of this first effort resulted in a continuing series of flights. Early on, Chuck saw the possibilities that balloon flights could offer for aerospace education. Since a balloon can reach the edge of space very economically, it became practical for students to actually build a simulated satellite and fly it.

Doug Craig, a local teacher in Franklin, Indiana, who taught an aerospace class, teamed up with Chuck to involve his students actively in the development and the flight of a balloon payload. Their first flight in October of 1989 involved nearly 20 students who participated in the launch, flight and recovery of their simulated satellite project. Their satellite package contained TV cameras, voice and TV transmitters, and a radar reflector. The FAA and the Indianapolis air traffic control center were able to track the satellite and reported its location back to the student tracking team.

As a result of this flight, students learned through hands-on participation about satellite communications and problem-solving during a complex project. The project was so successful that the Indiana Department of Education has certified the first Aerospace Technology course in the US.

A series of flights throughout the past two years has involved students from Indiana universities, high schools, middle schools and elementary schools. In 1993 Chuck WB9IHS, along with five others, formed a nonprofit corporation named WindTrax, Inc., to help schools and teachers participate and find resources and funding for these projects.

The Purdue WindTrax system

The basic WindTrax system consists of at least two TV cameras, a voice repeater and GPS tracking. The ATV package for the Purdue flight was built by Terry Hudson KT9V and contained two B/W TV cameras. One camera pointed straight up toward the balloon and the other looked out over the horizon. A small car compass was mounted directly in front of the horizon camera to give the ground observers a direction reference (this worked very well). The Wyman Research TV transmitter put out around 1.5 watts on 4339.25 MHz into a 1/4-wave whip mounted on the bottom of the payload. Control of the camera views and the Elktronics video ID was accomplished via a touch-tone control board and a Standard C508A miniature 2m HT. The large disk sticking off the side of the package provided a way to minimize the tendency of balloon packages to spin wildly (the many holes create drag and help to keep the package from spinning).

Purdue University's payload was coordinated through Ed Delp N9YTE and Dave Filmer WB9QPG. Dave built up an APRS system consisting of a Garmin GPS board, a MIMS packet controller board, and an Agrelo Engineering VHF transmitter. This payload weighed very little due to the small size of the packet controller and 2m transmitter. This payload did not fly due to problems with the GPS receiver.

The crossband voice repeater payload was designed and built by Paul Bohrer W9DUU. With an input on 144.300 MHz, this payload retransmitted on 444.85 MHz (modified Tekk FM transmitter) and 52.525 MHz (converted baby monitor transmitter).

The flight

As the tracking and ground stations were being assembled along the edge of the field, preparations began on the balloon flight train. Roger Grady K9OPO brought out his telescope, complete with a television camera adapter and monitor. During the flight he could see the balloon system clearly, even when it was over 30,000 feet high.

Just before inflating the balloon, a large trailer with lots of small doors on the side arrived at one end of the field. Within minutes a huge commotion distracted us all. Over 650 carrier pigeons had been released; they circled around the field once and headed off towards their homes. It turned out they were racing back to Detroit (220 miles away) at speeds between 40 to 60 mph. Now if only we could make an ATV system that would fit on a pigeon ... what a ride that would be!

"The Indiana Department of Education has certified the first Aerospace Technology course in the US."

Although the wind started kicking up during balloon inflation, the liftoff was smooth. It was a beautiful sight to see the balloon heading up to the edge of space. The video downlink showed panoramas of the Purdue campus, as it drifted off on its journey. The video dropped out shortly after liftoff (it turned out to be an overheated video modulator transistor), but came back as the inside of the package cooled. We were all treated to views of the blackness of space and the curve of the Earth. The car compass in the field of view of the horizon camera worked well and gave us a good idea of where the camera was pointing.

The crossband repeater worked great. Even mobile stations from Pennsylvania could be heard

Photo A. Terry Hudson KT9V prepares the ATV payload for liftoff. (Photos by Bill Brown WB8ELK.)

Photo B. (l to r): Paul Bohrer W9DUU, Victoria Pratt, Terry Hudson KT9V, Mark Garrett KA9SZX, Al Wolfe WB9OIH and Dick KC9AY recover the payload from the middle of a cornfield. (Photo by Bill Brown WB8ELK)

working through the repeater. The 1/4 watt output from this repeater has been heard more than 400 miles away during several recent flights. It also provided a great way for the chase crew to keep in touch as they tracked the balloon's progress.

The chase

Four chase vehicles and one chase plane went after the balloon shortly after launch. Two of the chase crews had either Doppler or left-right DF equipment onboard. One car used a large beam with success.

After the balloon burst (over 100,000 feet up), the package began its parachute ride back to earth. The downlinked video signal gave us some great landmarks. I-74 could be clearly seen during the last couple of minutes before landing.

Paul Bohrer W9DUU and Dick KC9AY were close enough to actually see the parachute as it descended into a corn field. Kim Miles KB9JQO was tracking the ATV signal with a left-right DF box aboard his airplane. Two vertical antennas for the 70 cm band were sitting on the dash of his plane. He could easily track the balloon, just as if he was tracking a VOR airplane beacon. Kim caught up with the payload and circled it as it came in for a landing. Mark Garrett KA9SZX and Al Wolfe WB9OIH were tracking the signals with a large beam and were just a mile west. Terry Hudson KT9V was a mile east at landing. I was tracking the signal with just a two-element quad with my friend Victoria. We all converged on a large farm to ponder the best way into the field.

It turned out that the balloon had landed as far from any road as it possibly could (one of Murphy's Laws for balloons). Not only that, but after tromping through a soybean field for about a mile, it appeared that the payload was on the opposite side of a rusty old fence another 100 yards into a field of very tall corn!

I watched my portable TV set from the soybean field as the rest of the crew headed into the corn. It wasn't too long before I saw a pair of tennis shoes (Mark KA9SZX) walk in front of the camera lens and heard distant shouts of glee! Everything was recovered in great shape, although the chase crew and vehicles were thoroughly coated with dust and pollen.

Future flights

As of the time of this writing, another balloon was flown from Eastern Elementary Middle School in Greentown, Indiana. The crossband repeater was heard as far away as 410 miles by Bob Wilson WA4ZZW in Priceville, Alabama. In two weeks another flight is scheduled to be flown from New Augusta Public Academy of Indianapolis, Indiana. For more information about the WindTrax program and upcoming flight announcements, check the World Wide Web at: http://klingon.cs.iupui.edu/~pacer/new_augusta/windtrax.html. This online site is courtesy of Indiana University, Purdue University at Indianapolis, Dept. of Computer and Information Science. *Thanks to Chuck Crist of WindTrax, Inc., for the above information.*

Hams on the Radio Information Highway, Part 1

The World Wide Web will help you enjoy ham radio more than ever.

Jack Heller KB7NO
712 Highland Street
Carson City NV 89703

You may smile at the message, "The band sure seems dead to night—maybe all the hams are over on the Internet ... hi." It came across my PACTOR screen the other evening when I asked a fellow ham if he used the Internet. Of course, he meant his remark to be taken as humor. After all, aren't serious hams content to communicate over the airwaves? By airwaves, we must include club meetings and the occasional "hot-air session" at the coffee shop. So, maybe, that isn't so different from the Internet.

But what about the Internet? What can it do for you? Did you know there are over 500 ham radio related sites on the World Wide Web (WWW) of the Internet? I didn't—until I started checking out ham sites a few weeks back. There truly is something for everyone, from the non-ham who would like to know more, to the most advanced DXer, contester or experimenter. Hams the world over are interested in other hams. It happens at clubs, over the air, and now it is fun and easier than ever to exchange information quickly with thousands of polite, friendly and helpful hams on the Internet. For the ham or wannabe ham, the safe, comfortable world behind the keyboard can be ideal for exchanging ideas with other hams willing to share their hard-earned knowledge.

Just for openers: Did you know there is a web page that allows you to access current callsign information? It's http://www.ualr.edu/htbin/callsign.exe. It took me less than 10 seconds to get the data back on my call after entering KB7NO. That is *fast*, especially when compared to the time it takes to use the print version I have on the shelf. Don't let all those long strings of itty-bitty letters intimidate you. You can often access a web site by clicking a hyperlink reference. Then you can save the address in your "bookmark" for an automatic "revisit" another day.

If you use Netscape® (see **Fig. 1**), you can easily find any of hundreds of ham-related web sites and news groups, as well as ham files you can download

> ***"It's obvious why some people are hooked on the Internet."***

from the Internet. The easiest way to enjoy "instant success" is to go to the World Wide Web and put one of the search engines to work. Once you get to the search page, you will find a box to type in the subject you want information about (amateur radio). Click "Search" and you are on your way.

You will also find this includes most of the manufacturers, such as Icom, Kenwood, Yaesu and many others, who provide equipment for our hobby. These commercial folks are doing their best to make your visit to their "virtual store" worthwhile, and some of their bargains are offered only on the web sites.

The real excitement begins when you stop at sites such as the University of Arkansas Little Rock Amateur Radio Club home page where the online callbook referred to above is located. This well-appointed page can also link you to the

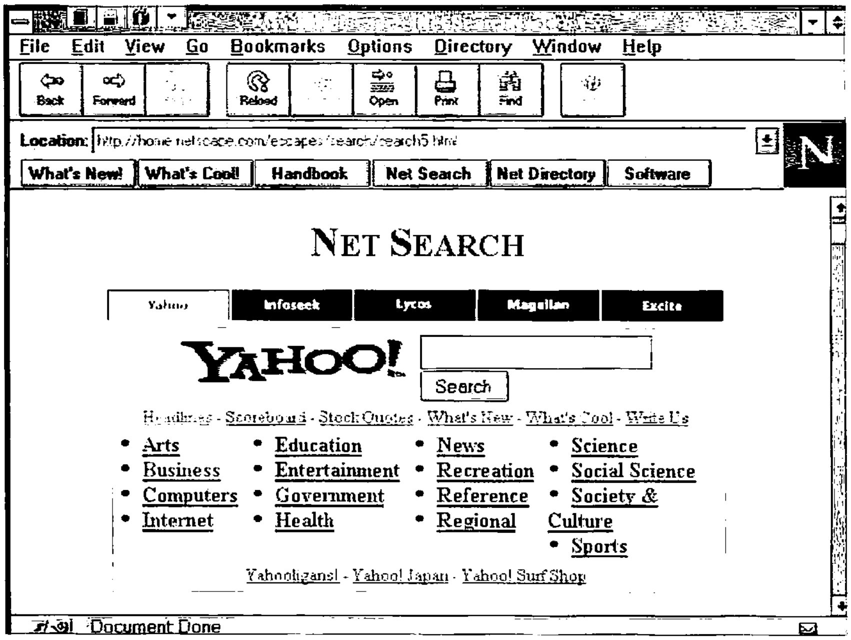

Fig. 1. Netscape features five different search engines. I suggest Yahoo! for simplicity and speed, at http://www.yahoo.com.

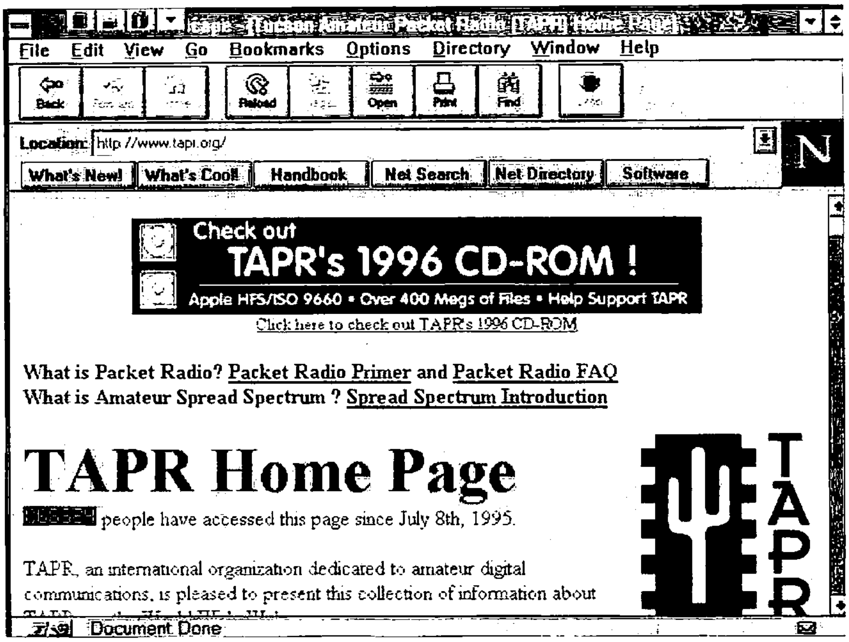

Fig. 2. The Tucson Amateur Packet Radio homepage is an excellent place to get up to speed on packet and all that goes with it, at http://www.tapr.org.

W1AW page, their own amateur station page, *Yahoo!*, FCC Part 97 database, and two great ham general interest sites.

When I first visited this site, I encountered one of the Internet gremlins. Two of the links did not work that day; so many systems are interconnected that occasionally the input acquires a hiccup and a link won't work, but problems of this nature usually heal within a few hours or days. You get used to it (I simply went on to other sites). You can always go back another time. The results will probably be even better when you do return.

Looking further, AMSAT presents its own exciting page (http://www.amsat.org/amsat/AmsatHome.html) where they tell all about their program and how hams are making it possible. There is a display of actual photos of the work as it is being performed on the amateur satellites.

The Tucson Amateur Packet Radio home page (**Fig. 2**) is very well done. This is a "must-see" for anyone with even a fleeting interest, up to and including those deeply involved in digital concepts.

Another great web page you won't want to miss is NØXIC's Amateur Radio Resource (**Fig. 3**). Marc has put an enormous effort into this presentation. You can get information on becoming a ham, find answers on about any ham topic and there are links to many web sites and other web sites. You can easily satisfy your need to read—and then some. On this page, you will see over 75 references with links to other ham-related sites that require only the click of a mouse to provide you with another world of information to absorb.

"Manufacturers want to make your visit to their 'virtual stores' worthwhile, and some bargains are only offered on the websites."

I printed a copy of this web page to keep for reference. On my hard copy, I marked 21 places to visit as time permits. They include many informative sites with extensive information about amateur satellites, solar activity and solar images, antennas, and club web sites.

Marc's page is only one example of what many hams are doing to make traveling the Internet pleasant and informative for the rest of us. There are many more such interesting sites, and the creators are constantly upgrading them to make our surfing ever more productive.

The marvel of the hyperlink makes all this so easy that I can see why folks are hooked on their own niches of the Internet. You look at one of these web pages and find an invitation to click a hyperlink line with the mouse and you are suddenly in another ham area and it may just as easily lead you to another. Before you know it, the XYL is ringing the dinner bell.

All this makes a great tool for you to connect with hams who are helping others in just about every facet of our great hobby. Yes, if you haven't already gone on line with your computer, now is the time. There are a number of hams who check in regularly on this "land-line" based system. (Actually, the Internet doesn't rely solely on phone hookups. If it will make you feel better about participating, there are radio and satellite links discretely working in the system as well.)

Now, I am going to tell you how easy this is to do (if you aren't already doing it). You won't need a degree in computer technology, and you won't even be required to pass a code test. If you have a relatively modern computer such as a Windows-based IBM compatible or a Macintosh, you have most of the equipment covered.

The cost isn't outrageous to add a modem to one of these computers and the software is relatively low-buck. You will spend about $70 to $120 for a good modem. Many new computers are sold with the modem installed. The current standard is rated at 28,800 bits per second (bps). I am still using a 14,400 bps modem which "they" say is barely adequate. It is doing an OK job for me, but if you purchase new, go with 28,800 bps.

The modem is easy to install in the IBM style computer. Just remove a cover at the back of the chassis to expose the end of the slot that makes room for the phone lines and plug it in. Macintosh folks always have an Apple guru lurking nearby for advice, and they assure me Macs are at least as easy to configure as my clunky 486 IBM clone.

Once your modem is installed, you need terminal software to tell the modem to ring a telephone somewhere, and you are nearly ready. Most modems come with a trial package of software to get you going. If you are going to go strictly with a phone connection to the Internet, you will need to find an Internet Service Provider (ISP).

You have several choices when choosing a provider. Some of it depends on where you live and if that

results in long distance charges to connect. You may fare better if you check with one of the major online services such as America Online, CompuServe or Prodigy and take advantage of their Internet access. The rates of the major services are competitive. You just need to find one that is close and has a fairly high-speed connection (minimum 9600 bps).

A good provider will answer your questions and be sure you get going in the right direction. He is likely to have software for little or no cost that will be just the ticket. The current favorite Internet "browser" (terminal program that decodes what's on the Internet and displays it on your monitor) is Netscape and it's free! I am using the latest version, 2.01, that I downloaded over the Internet directly from the company as a 90-day "evaluation" copy. One day, we'll all have to buy the finished product, but for now .... Your Internet provider can tell you how to get your first copy, and how to get the only other piece of software you need; a "dialer." The standard of the industry is Trumpet© and an

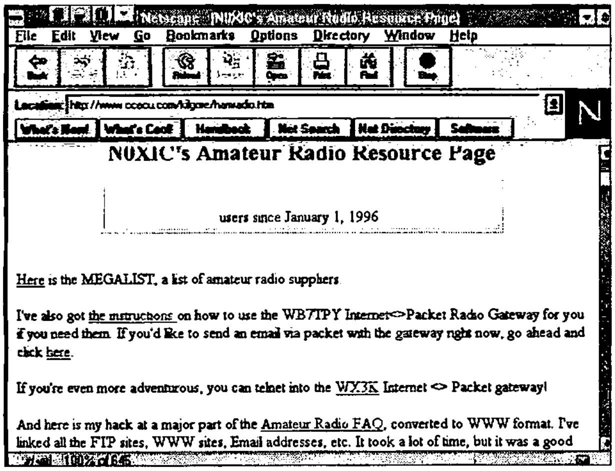

Fig. 3. NØXIC's references touch on nearly every facet of ham radio—a worthwhile visit at http://www.ccecu.com/kilgore/hamradio/htm.

evaluation copy is available that will cost you $25 (money well spent) when you register it within the first month of use. If you don't register, it self-destructs.

If you are using Windows 95©, you can configure that operating system to make the connection for you without using a dialer such as Trumpet. However, it is a little tricky and you will need some specific guidance. Though I haven't made the installation myself, I have the step-by-step instructions from Netscape to do this. I furnished them to a friend who still had to call his ISP to fill in a few blanks left out of the instructions. Now his works faster than mine. I guess that means I must break down and install the Windows 95 someday.

One of the really neat features of the new version of Netscape's search page is the option of most of their search engines to not only perform web searches but to search the newsgroups for material by topic. It all works great and you must be careful—don't get hooked. You could easily run out of time for life's necessities (chasing DX, rag-chewing, repairing your antenna, etc.)

Next month, we will explore Usenet newsgroups.

Never say die

Continued from page 42

You probably saw the TV exposé of what happens when a Wal-Mart® or Sam's® comes to a town. The lower prices soon put all local competing merchants out of business, often leaving main street looking like a ghost town. Then, if the Wal-Mart doesn't make enough profit, it folds up and leaves the people with no place nearby to shop. The local stores don't come back. Most of them had been in business for several generations of family ownership. And who's going to start a clothing or department store in a small town today when a discount monster can open up at any time and wipe everything out?

The next obvious step in the ham field is for the manufacturers to eliminate the no longer needed middlemen by going factory direct. This is what Swan did many years ago. But they got forced out of business by the then still strong dealers who wasted no time in telling any ham customer how rotten the Swan junk was.

Back when I started *73* in 1960 I had over 850 ham stores carrying the magazine. Today there are an estimated 50 ham stores left, and many of those are hurting. I'm sure the retailers who are left really appreciated it when *QST* ran an article on how to whip-saw dealers to get the lowest prices.

With so few dealers, much of their business has to be done by mail order if they are going to survive, which makes it even easier for the major manufacturers to be in direct competition. And since few dealers these days are able to handle repairs ... well, you get the picture. If the dealers are going to survive they'd better organize in some way, otherwise the handwriting is on the wall. Radio Shack®, catering to the no-coders, is skimming the cream, and all it takes is a couple of feet of floor space in their stores. If that.

Snow Job

Art Bell W6OBB called the other day and asked if I would be a guest on his radio talk show again. My last guest shot on his show resulted in several thousand letters and faxes and generated a lot of interest in amateur radio, including a bunch of new *73* subscribers. I also generated a good deal of interest in my list of "books you're crazy if you don't read." The list had 49 books at the time. The list brought in a bunch of letters recommending other books that really should be on the list. I bought 'em and read 'em. In some cases the listeners were right, so I've added the books to my list. It's up to 88 books now, and I've got a stack of over a hundred more recommended books sitting here yet to be read. Some look really interesting, too. Nope, no fiction.

So I said okay, let's do it again. I was on with Art for four hours. I forget what all we talked about, but we started off with amateur radio, with me explaining that as a direct result of my interest in the hobby I've had some amazing adventures and a wonderful career. Imagine, working in your major hobby!

For the first few days after the show I was getting a stack of letters about 18" high every day. Over 4,000 in the first week. Plus my poor fax machine was grinding out faxes day and night. This happened a week before the Dayton HamVention, so I was sure glad I'd decided not to go this year. I've been spending about 18 hours a day opening letters, duplicating my booklets, and then addressing, stuffing and mailing envelopes.

My most popular booklet is the five-buck 28-page recommended book list. It has a discussion of each book. The books cover many aspects of health, education, history, science, etc. Many are books I've reviewed for you in my editorials. Maybe you noticed.

Rich? Why Not?

My next most popular book was the one I wrote as a result of the requests from my first guest shot last November. Art and I had been talking about TVI and I suggested that the best solution was the one I went for—living on a 200-acre farm with no neighbors within a mile. Art pointed out that this takes money. I said that, heck, making money is easy, once you know the secret. Our social and educational systems make sure that 99.9% of us never make much money. I didn't figure it all out until I was 28. By the time I was 30 I'd made my first million. I got off the quiet desperate treadmill to oblivion. I was upset when I discovered that by not knowing the secret I'd wasted over 10 years of my life. Drat!

So I wrote a booklet on "Making Money, A Beginner's Guide." It's selling like crazy. Oddly enough I wrote a very similar book 35 years ago and couldn't sell it to young possible entrepreneurs, even at $1. Now those same people are in their 50s and they're beginning to

Dear Readers,

It's a survey! It's a drawing! Win a prize and money!

73 needs your help! 73 really appreciates your sending your feedback cards to us. Now, we'd like to know something about you and your hamshack.

Return this survey and take part in 73's random drawing of all the survey responses received by December 16th, 1996. The winner will receive $100.00 cash and a Life Subscription to 73 (okay, so you are already a "lifer"...enter anyway and give your "prize" to your grandchild). We'll announce the winner's name in our February '97 issue. So, please answer the questions below on an 8 1/2" x 11" sheet of paper and return them to:

73 Amateur Radio Today
70 Route 202 North
Peterborough NH 03458
Attn: F.I. Marion

FAX at (603) 924-8613 or
E-mail: Design73@aol.com

Be sure to include your name, callsign, address, and phone number. Keep those reader service cards and the feedback cards coming. Good luck!

1.) a. Do you subscribe to *73 Amateur Radio Today*?
b. What do you like most about the magazine?
c. What do you like least about the magazine?
d. If you're not a subscriber, why not?
e. Where did you get this issue?
f. What other radio magazines do you subscribe to?

2.) a. How old are you?
b. How long have you been involved with amateur radio?
c. What encouraged you to become involved with amateur radio?

3.) a. Do you belong to any radio clubs?
b. Which ones?
c. What do you do at meetings?
d. Have you or your club participated in any beneficial projects in your community?
e. Describe.

4.) How many hours per week do you spend on this hobby?

5.) a. Do you ever fill in and return 73's feedback cards?
b. If not, why?

6.) a. Do you send in the reader service cards?
b. Do you contact 73's advertisers because you saw their ad in 73 Magazine?
c. Do you tell them where you saw their ad?
d. Do the advertisers usually respond to your request for information?
e. How many products have you purchased from our advertisers in the last 6 months? 12 months?

7.) a. Do you find 73's product reviews helpful in selecting new equipment?
b. Do you contact any of the companies after reading a review to get more information?

8.) a. Do you read the "New Products" section?
b. Do you ever make purchases based on what you've seen there?

9.) How many "ham" related purchases have you made in the last 6 months? 12 months?

10.) a. Are you planning on making any large purchases in the next six months? If so, what? How much do you plan to spend?
b. If you read reviews of this product, would it influence which brand you would purchase?

11.) Of the major manufacturers, which 3 brands makes up most of your ham equipment?

12.) a. Do you purchase kits?
b. If so, what brands?

13.) Do you enjoy construction articles?

14.) a. Have you been on a DXpedition?
b. When and where did you go?
c. Did you do or see anything worthy of writing an article for 73?

Thank you for participating in this survey, good luck in the drawing.

wise up that there are very not many downsides to having a bunch of money, and surprisingly few benefits to poverty. Worse, they're the ones being downsized as computers and communications technology shrinks the management layers in larger companies. Suddenly they're faced with a need to find a new career, something they've never really considered before. There's just no market for ex-middle managers in their 50s. That's something for anyone still dependent on a paycheck to consider.

Bell's program covers the country pretty well. I've gotten letters from the Virgin Islands, and from every state.

But even with four hours I didn't get to talk about many interesting controversies such as past lives, reincarnation, near death experiences, out of body experiences, UFOs, contactees, Roswell, and stuff like that. Or go into detail on just how crummy our medical and school systems are and what can be done to fix them. How we have one of the most expensive medical systems in the world, and yet we're near the bottom in health. And ditto our school system.

But I did get to talk about the fun of making ham satellite contacts and things more dear to your heart. I talked up new communications modes and the pioneering fun and adventure they provide instead of grinding out routine hello-good-bye, please QSL contacts endlessly for years. Or calling into a roundtable or repeater, the ham version of hanging around the corner.

Adventure lies in wait, tapping timidly on your door. How much do you know about spread-spectrum communications? Well, if you don't, then dammit, learn. And then start writing articles so we can get some other readers fired up. There is no question in my mind that spread-spectrum digital communications is either going to be our main future system for communications, or we'll lose the whole hobby as the FCC sells off our frequencies.

Plan Ahead

Mankind does not have a good record for considering the future, so why should we expect anything but temporary expediency from the FCC? The Commissioners are political people; servants, not savants. They bow to the pressures of immediate money, and who the hell cares about what effect this might have on the 21st century? Or even beyond?

AC Power Overseas

You make the big decision: You'll go on a worldwide DXpedition, see the sights, ham from exotic locations, pick up a few souvenirs, and take about a gozillion color pictures. All you need to do is get a passport (takes from three to eight weeks, sooner if you can prove urgency with a ticket that shows an imminent departure date—bring a note from your mommy), stop by a few consular offices to obtain visas (don't want to get arrested at the airport), pack some clothes and the ham rig and take off. Right? Wellllll, maybe not.

There are a number of things that must be tended to before leaving. Not every country is going to let you operate, or, for that matter, even bring radio gear into the country. The ARRL (225 Main Street, Newington, CT 06111; hq@arrl.org) can advise you on reciprocal licensing and other issues relating to hamming in various countries. Some old hands could also tell you about the specifics of each country (bribes? never ... I think they're called "paperwork facilitation fees"). One chap told me that a certain Latin American country almost always imposes a huge import tax on radio gear brought into the country in the cargo hold of the aircraft, packed in factory boxes. On the other hand, if you carry the radio under your arm, and make it look a bit old, a $20 bill to "facilitate paperwork" seems to do the trick. He's done that with a couple rigs, including a TS-440 recently (would you believe it, the guy's a missionary ... *they* don't "facilitate paperwork," do they?).

"Bribes? Never ... I think they're called 'paperwork facilitation fees.'"

Another major issue is the matter of AC power for the rig. Many ham rigs are equipped with AC power mains selector switches on the back of the rig (or of the power supply if it is separate). In other cases, there are taps on the transformer for different voltages. For example, one species of the TS-520 I saw had a 120/240 volt switch on the rear panel. But a service technician showed me something that was not hooked up. The schematic showed several additional primary taps that could accommodate primary voltages of 100 to 380 volts, depending on which was hooked up. It only makes sense. After all, why would the manufacturer make different transformers for different countries when a few taps cover a lot of QTHs?

In some cases, you will need an external transformer adapter for the power supply. Don't rely on those little transformers that run your electric shaver, for they are too low-powered. Isolation transformers come in 1:1 and 2:1 ratios, so they can accommodate a variety of power situations. The most useful of those have a 120 volt AC outlet on one side, and a plug and voltage selector on the other. Transformers of that sort are not rated for power (i.e. watts), but rather are rated for volt-amperes (VA). VA is the same as watts, except for the power factor.

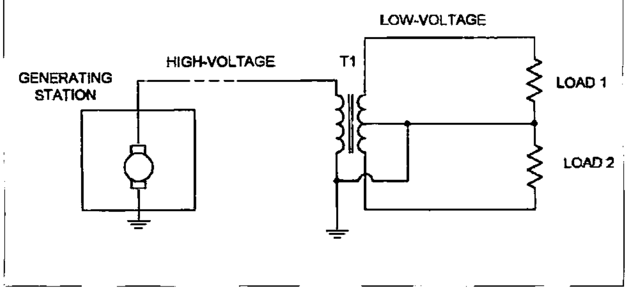

Fig. 1. North American power distribution system.

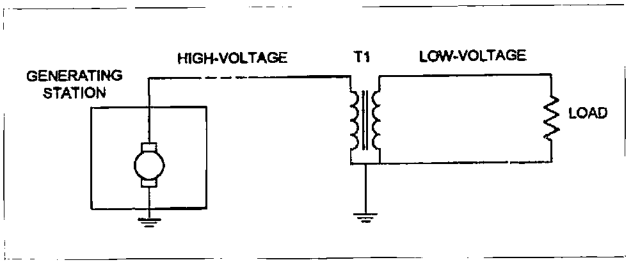

Fig. 2. Alternate power distribution found in some countries.

Power distribution systems

Fig. 1 shows the standard AC power distribution system in North America. The generating station produces high voltage AC power. It is distributed at high voltage so that the current is reduced (for any given wattage), and that makes transmission through lossy transmission lines less of a headache. It will go through a number of step-down transformers, but I've shown only the one outside your house. It will have a high-voltage primary, and a 240 volt center-tapped secondary. The center tap is grounded. If you want a 240 volt outlet, then you take the voltage across the two ends of the transformer. But if you want 120 volts, then you take the voltage from ground to either end. Two "circuits" can be served (shown as LOAD 1 and LOAD 2). Of course, in a real system there are switches, fuses, circuit breakers and a distribution box as well as the transformer shown in **Fig. 1**.

Many overseas locations use the same type of distribution system, although the voltages may be different from those used in the United States and Canada. Other countries use a single secondary distribution system, such as that shown in **Fig. 2**. The voltages available will be listed in the form 120/240, or whatever voltages are actually present. This system is pretty much the same up to the primary of the transformer, but the secondary is not center-tapped. The voltage listed for those countries will be only one level.

Various plugs and sockets are found around the world. **Fig. 3** shows some of the different types of plugs that will be found. You will need to either buy adapters to go from our system to theirs, or buy new plugs when you arrive.

A booklet for you

If you want detailed information about plugs, voltages and so forth, the U.S. Government can supply a little book for $9.95. Ask for *Electric Current Abroad*, publication number PB91-193383. Write to National Technical Information Service, U.S. Department of Commerce, Springfield VA 22161. Call 1-800-553-NTIS, or in the Washington, DC, calling area, 1-703-487-4650.

Connections ...

I can be reached via snail mail at P.O. Box 1099, Falls Church VA 22041, or via Internet E-mail at carrjj@aol.com.

NEVER SAY DIE

Continued from page 53

When America was discovered the Europeans came over, got rid of the Indians, and then started exploiting the land in every way they could. They dug for gold, silver, lead, coal, oil, and so on. They cut down the forests and planted crops. They just about wiped out those annoying buffalo and much of the other wildlife (like wolves). I think there's a small area of virgin forest left someplace in Pennsylvania. Never mind what this cutting of forests has done to our land, water, and the whole ecosystem. If you're interested in the long-term changes cutting down forests makes, you'll want to read *Living Water* by Alexandersson (ISBN 0-946551-1-57-X, 162p, 1995, Gateway Books). He explains why it is impossible to make a Stradivarius violin anymore. The new growth forest trees grow too fast to make the solid kind of wood they had 200 years ago. There *isn't* any more. They're even busy clearcutting the virgin forests of Borneo to build houses in Japan.

We talk about the world's oil supplies maybe lasting another 50 years. Well, we have to make sure people right now have jobs, and who the hell cares about what problems we're leaving for our grandchildren. And their grandchildren. That's fine as long as you refuse to read what is known about reincarnation. Did you know that the Council of Constantinople in 533 AD eliminated the concept of reincarnation from the Christian religion?

Between ham radio, cold fusion, our major social problems, and the weird stuff, I can liven any talk show, so if you know a talk show host, please have him get in touch with me so we can drum up a few more hams. It's Wayne Green, Peterborough NH 03458. I even check Design73@AOL.com now and then.

Not that we can honestly blame the government, nor even the big corporations which run the government, about ignoring the future. After all, most of us are doing the same thing ourselves by smoking, drinking, using drugs, getting fat, and other forms of there-is-no-tomorrow slow suicide.

Prestige, a Zero-Sum Game

Our universities and our scientific elite are powered almost entirely by the prestige game, and the bottom line for the universities and our country is zero. Our scientific elite produce endless scientific papers about minutia, slicing the baloney ever thinner.

If you think I'm exaggerating then you haven't done much work with a college or university. I have, and with several. And you certainly haven't read any books on the state of our colleges today. Like the wonderful book by the president of Hillsdale College, George Roche, *The Fall of the Ivory Tower*. Yes, of course it's on my list of books you're crazy if you don't read.

Okay, so what? So our colleges are turning out mush-headed semi-literate, drive-deprived graduates. And this is the vanguard we're depending on to compete in the 21st century global market?

I tried hard to help Rensselaer Polytechnic Institute pull itself out of its 19th century time warp and leapfrog into the 21st century. I consulted with the faculty and the president of the college. I donated a bundle and became a Patroon. I was put on the Board of Overseers and then ignored (along with the other Overseers). I was enormously honored by being appointed to the RPI Council, where I was again largely ignored. "Just shut up, call the alumni and ask for money." I was named their first Executive In Residence. On the thin positive side, I revamped

Cleaning Up Your Act!

Here's another tip for the Alinco DR-1200T 2 meter transceiver, for cleaner sounding transmit audio when using the supplied electret hand mike. Though the particulars will vary, it should be applicable to other radios.

Electret condenser microphone elements are inexpensive and have very "flat" response curves, but they require an external source of low-voltage DC power to operate the built-in FET preamp. An electret element puts out so little energy that preamplification is needed immediately, and an FET preamp is built into the element as an integral part of the tiny package. The external voltage to power the preamp usually comes from the transceiver with which the microphone is being used, although a battery within the mike's case can also be used. When the transceiver supplies the mike power, it usually comes in on one of the unused mike connector pins, and generally from the transceiver's +5 VDC Vcc line. If that line also feeds any digital ICs, and filtering of the Vcc line isn't close to perfect, the +5 VDC line can sometimes introduce noticeable digital noise superimposed on your mike audio.

Listen to your transmitted signal on another receiver—with the CTCSS encoder off and in a quiet room—to see if this might

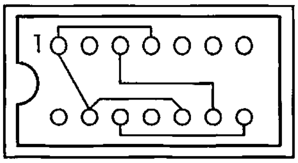

Fig. 1. The 74LS74 is notorious for the number of jumpers needed, and serves as a good example of how Frank KB4ZGC's idea can be implemented to avoid the "under-PC-board jumper jumble."

be true in your case. If anyone has complained about your on-the-air audio quality, make the quick test mentioned above.

If you get digital noise or other unidentifiable pops and clicks from time to time on your transmitted audio, the cure may not be difficult, depending on your transceiver. You can try simply more filtering—right at the mike connector pin that supplies the DC to the mike element, in the form of an additional capacitor from that DC pin to ground (trying different values to see if there's any improvement). If that doesn't work, which is often the case, then it's on to the next step, which is what I did with my own DR-1200T.

Probing around with a little battery-operated, solid-state, high gain audio amplifier (via a .1 µF disc cap), I "listened" to the various DC lines in the DR-1200T. Some points are much noisier than others, some lines very "clean." It's a situation that may be difficult to predict from the schematic alone, but it's a cinch with the little "noise tracer" amplifier! By the way, this idea works in many other troubleshooting areas as well (hum problems, cross-talk, noise spikes, etc. on the DC lines). In my own DR-1200T, I found that the output pin on the 7808, 8 volt regulator (IC-1) sounded very clean, so I changed the DR-1200T's mike voltage source from the +5 VDC Vcc "noisy" line to the +8 VDC "clean" line. In the DR-1200T it's something of a chore, but still doable. The reason is that Alinco uses PC board traces to feed the mike connector, and the connector itself is part of the "display" PC board, so traces must be cut and rerouted. Other radios, with individual "actual wires" being fed to the mike connector, may be easier to convert.

On the rear (foil) side of the display board, two jumpers will need to be added to reroute the +5 VDC line around the mike connector. Since the display board is a double-sided PC board, the opposite component side must also have one trace cut; no jumpers need be added on this side of the board. You can trace the circuit out if you wish, but these steps should effectively isolate pin 5 of the mike connector; now "clean" +8 VDC can be brought up to the connector, via a new "direct" wire, from the +8 VDC regulator mounted on the rear wall of the transceiver's case. The circuit board is crowded, the traces close together, but if you take plenty of time and common care, it should go smoothly.

More

Another side to the "clean DC" issue is obtaining a reasonably noise-free mobile environment. Mobile noise can be that which is only perceived in the mobile's own receiver, and that which may also be impressed upon the mobile's transmitted signal. Both can be problems, in that the solution is often "cut and try."

There are a few things, however, that every good mobile installation should automatically include, whether in a car, motor home, boat or private plane.

First (as touched upon in John Ayers AA1IC's tip in last month's column), is running a separate "clean" battery feed—one that only feeds the ham transceiver—directly from the vehicle's battery. Hopefully, such a "dedicated" feed will be relatively free of switching noises generated by computers, the ignition system, vehicular sensors, etc. The feed should consist of a separately fused battery run made with a gauge of wire heavy enough so that the voltage drop across the wire's resistance is insignificant at full transmitter power drain. Often, this alone will solve many mobile noise problems. But if it doesn't, here's a simple test you can perform to see if the noise is from radiated energy or if it's coming in via the DC power feed. Simply disconnect the radio's antenna. Does the noise disappear? If so, then it's radiated noise being picked up by your antenna; that's generally more difficult to troubleshoot. If it doesn't disappear—or if enough still exists to be a problem—then it's likely to be coming in via the radio's DC power feed.

What if you've run a separate power feed, directly from the battery, of heavy-gauge wire, and a significant amount of noise persists with the antenna removed from the set? You can try shielding the feed cable from the battery to the radio, using the shield and jacket from a length of RG-8 coax from which the center conductor has been removed. It shouldn't be necessary for most installations, but it's worth trying (and inexpensive enough) when the noise is persistent. If shielding the feed cable doesn't do it, then a choke in series with the DC power to the transceiver may help. Parts Express™ (1-800-338-0531) lists commercially-made chokes up to 4.7 mH, made of #14 wire, and exhibiting 0.52 ohm of resistance or less. They also carry computer grade very high capacitance power capacitors (one farad!) that will not only help filter noise, but will also smooth out any voltage variations from peak surges during SSB voice operation—the next best thing to having the battery itself right behind the radio.

If most of the noise you hear in your mobile transceiver is coming in via the antenna, then you'll have to settle in for some real hunting. Ignition system wiring is usually the best place to begin, either installing new resistance ignition wires or going full tilt into a specially-made shielded system; it mainly depends upon how much noise you can comfortably live with. Today's cars also can have one or more computers controlling vehicular functions. Computers generate square waves by the score, and square waves have lots and lots of harmonics; many of these harmonics will appear within the ham bands. Some of the slip-on, thread-through, clamp-over ferrites available today will tame computer generated noise and harmonics without having the slightest ill effect on the computer control system (they only absorb unwanted RF energy). Where they're needed and how many

will be necessary is the "cut and try" part mentioned earlier; it's anyone's guess. Usually, it's best to start at the computer's input and output leads, installing the ferrite cores as close as possible to the shielded computer case itself. From there, it's the sensors on the various parts of the engine that can be given attention, again, as close as possible to the sensor body itself. A shop manual for the vehicle is almost a must at this point. Avoid any bypassing that requires direct electrical contact with the vehicle's electronics; try to stick to non-invasive ferrite absorptive devices or you'll run the risk of compromising your vehicle's control circuitry. Perhaps most importantly, take your time and attack the problem systematically and in small chunks, and thoroughly check out each step you make.

A spicy DIP chip

From J. Frank Brumbaugh KB4ZGC/W4LJD: "I've found this wiring technique to be helpful at times, so I'm passing it on to others who may want to try it. Sometimes Dual Inline Pin (DIP) chips (particularly those in the 7400 family or even the venerable NE-555) require a number of jumper connections among several of their pins to make everything operate correctly. This can result in a jumble of wires or a complicated PC board trace layout in order to accomplish the task. But here's another approach: Carefully solder very fine wires—taken from an untwisted short length of ordinary stranded hookup wire—and make some of those jumper connections right on the bottom of the chip itself. Take care to avoid any shorts, and make the connections high on the IC's "legs," but prewiring some chips like this can save a lot of underboard crosswiring later on. This jumper prewiring can be done on the IC sockets instead, before installation, if your project uses sockets instead of the chips themselves soldered directly to the board. Even if it isn't practical to prewire every jumper needed, the more you can eliminate using this technique, the neater the finished board will appear. Take a look at **Fig. 1** for a couple examples of this technique."

Moderator's note: Frank has a clever idea here; it might also be a good idea to note on the project's schematic which jumpers are hidden, perhaps showing them in dotted outline.

Never assume

Last fall I made a "lights on" alarm (a buzzer sounds when the lights are left on without the engine running) for one of my cars that was missing this feature from the factory. The circuit worked like a charm on the bench and ditto when I installed it in my car. Then the cold weather came. When the temperature dropped below freezing, the circuit still worked, but the buzzer would sound for a few seconds (even when it wasn't supposed to, that is) when the lights were on but the car *was* running. The colder it became outside, the longer the circuit would take to operate correctly. My wife, Sue KA9UCK, is very patient, but it was even getting to *her*!

The problem turned out to be in the relay I had chosen to key the buzzer on and off; a small, sealed, good-quality relay, but it was also very temperature-sensitive. Apparently, the contact arms in it deformed enough in the sub-freezing temperatures to make contact when they shouldn't have, but after heating up just a bit (from current flowing through its coil), the relay operated correctly. I thoroughly tested the replacement relay in my lights-on circuit for temperature sensitivity (by putting it in the freezer for a while) before committing it to the underdash of my car again! Case closed, lesson learned.

We've all run into these problems with equipment that doesn't operate as expected under all extremes of temperature, and it might be a worthwhile effort if you were to jot down some of the more interesting ones you've encountered and I'll include them in the column at some point in the future.

Cold testing a piece of mobile gear is relatively easy; just put it in the freezer for a while. Heat testing is a bit more tricky. The inside of a closed vehicle can reach very high temperatures during the summer months, but testing for extreme heat—by putting the item into an oven—is often dangerous. You don't want to damage your gear with the test! Has anyone devised a reasonably safe heat-test setup, for subjecting mobile ham equipment to summer heat extremes, without too great a risk of permanent damage? You folks in the desert areas should be experts on this one!

Mood lighting

From R. Gary Bartlett VE1RGB: "To me, there is something very calming and perhaps a bit romantic (in the old-fashioned sense of the word) about a ham radio station that makes use of the built-in panel and edge lighting that comes fitted in most ham gear as the primary radio room lighting. It's sometimes necessary to supplement the equipment lamps with some sort of external spot lighting to illuminate a work surface or control panel, but the use of dimmer, rather than brighter, lighting is often a better choice. Having spent some time as an electronics systems operator on a Canadian military subhunter aircraft, often at night, I suppose that I feel most comfortable under the dim light of an operations area, but I've a hunch that many other hams feel the same way. I still enjoy listening on 3.4793 kHz, late in the evening, as the Gander and Shanwick Oceanic Air Traffic Controllers are trading position reports and vectoring their flights across the Atlantic. I try forming a mental picture of where all of those airplanes are, and what they're doing, where they're going and the many countries and companies they represent.

"How can you replicate this mood in your own shack? In our aircraft, we used what was known as a Grimes light, which had a selectable clear and red front lens. It also had a dimming pot and a focusing adjustment. It came with a helical coil cord (like a telephone handset cord) and a quick-disconnect mount, so the light could be removed for viewing some deep, dark recess if needed. In an aircraft, that's usually down

**** No data available**

Table 1. Transmission line loss table for coaxial line (all values are in dB of loss per 100 feet).

near your left foot, where a dropped pencil could easily jam the mike foot switch. If you have any military surplus stores in your area, it might be worth checking with them to see if they have anything resembling what I've just described. You might also peruse any RV or camper supply catalogs, and/or dealers in your area, since lights of a similar type can sometimes be found in recreational vehicles. Even if you can't locate the exact Grimes light, you might be able to modify a light that is readily available, putting a little of your ham ingenuity to work.

"Try to stick to 12 or 24 volt lighting if you can; it's much safer and easier to use than the much higher line voltage systems. A husky 12 volt transformer, properly fused, is all that's need for an AC low-voltage lighting setup, or your station's 12 volt DC power supply can be used to power some lamps, as long as the supply's current limitations and adequate fusing precautions are observed.

"Dimming the lamps on an AC system requires a rheostat capable of dissipating the correct amount of wattage, whereas a DC system is able to use some of the modern adjustable regulator chips and a simple pot to vary the light output from your low-voltage lamps. An LM-317T is a good one to look into for this purpose (see the drawing in **Fig. 2**).

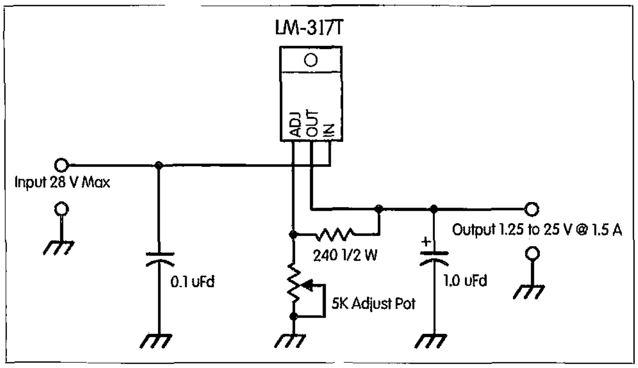

Fig. 2. A simple DC control circuit for use with the low voltage station lighting fixtures described in the text.

"External wiring to the lamp fixtures themselves should match the fuse rating and current drain of each lamp in a leg, and the use of insulated and adequately marked terminal strips makes changing or expanding the system a breeze. Low voltage wiring is much easier to work with than its line voltage counterpart, but care still must be exercised to ensure that all wiring and connections are safe and low resistance. Keeping an up-to-date diagram is desirable and not at all difficult to maintain.

By the way, if you happen to run across some particularly good hardware (fixtures, connectors, extensions, etc.) in implementing this idea, please send them to this column's moderator so that we can all share in your discovery."

Super table

From John McDermott N4YIC: "Here's a reference table of popular coaxial cable line-loss data that you can add to your 'Ham To Ham' pinups! It's certainly not original, but it does provide a fair amount of information in one easily posted piece (see **Table 1**). It lists 32 coaxial cables, along with the normal loss data, from 10 MHz all the way to 3,000 MHz (3 GHz) in an easy-to-read format. I hope it's as useful to others as it has been in my ham station."

A charge slip

Here's a tip for those of you who might own the Yaesu FT-209RH or FT-709RH handheld transceivers specifically, but may apply to other models of handhelds as well.

There are usually two choices for recharging a handheld's battery pack: 1) using the optional drop-in charging stand via the charging contacts on the bottom of the battery pack, or 2) charging the pack with the small wall-cube transformer/rectifier via a little charging jack on the bottom or back of the pack. But wait, here's a third alternative—one that allows you to customize a bit.

The Yaesu FT-209RH uses a "slip-on" battery pack, slipping on from the side of the transceiver, and then locking into place (many others use a similar scheme). My wife and I have two of the Yaesu handhelds, and a couple of the FBA-5 alkaline cell cases too. These are the battery cases made by Yaesu to house disposable alkaline cells, but instead, I've opted to install AA NiCd rechargeables into the FBA-5. This lets me put in new NiCds (or disposable alkalines) any time I wish (ever try to open a "normal" sealed NiCd pack?). The downside is that the FBA-5 doesn't have the familiar charging contacts on the bottom, not being meant to house rechargeables and also so that the user doesn't accidentally drop it into a desk charger with non-rechargeable

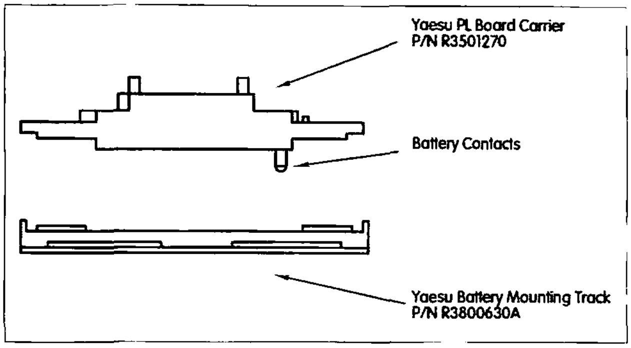

Fig. 3 . Side view of the Yaesu parts needed to make the slip-on charging adapter described in the text.

alkaline cells installed. In order to use NiCds with it, the cells must be physically removed each time recharging is needed—not the handiest of methods.

I wrote to Yaesu's Parts Department and inquired about the possibility of purchasing the battery mounting track and the battery contact plate assembly for the FT-209RH. These are the two pieces that are normally mounted on the bottom of the handheld itself for holding the battery pack in place and to make electrical contact with the pack's output pins. My reasoning was that if I had these two essential parts, I could build a "slip-on" charger housing for my FBA-5 packs, making recharging them a snap (pun intended). Yaesu quoted a very affordable price for the two parts that I needed (their R3800630A and R3501270), which are shown in **Fig. 3**, so I went ahead and ordered them, completing the job with the addition of the simple input jack and charge indicator circuit shown in **Fig. 4**. I'm now able to use the standard Yaesu NC-18B wall cube, along with the new slip-on adapter, for charging the NiCds in my FBA-5 packs, while the LED "continuity" indicator shows indication that the batteries are charging. Overall, a nice accessory to the battery lineup for these handheld transceivers. Of course, the slip-on charger can also be used with the normal non-openable NiCd packs too, providing you with a low-profile travel option.

Gobs of mods

More on the topic of equipment modifications: There are a number of BBSs (bulletin board systems) around the country with copious quantities of interesting modification files for commercially made ham equipment, all ready for downloading. And you don't necessarily have to have a packet station to access these files, though many full service packet BBSs also support equipment modification file downloads. But if you're not yet into packet, all that you really need is a computer with a fairly modern telephone modem and a terminal program that permits uploading and downloading of files. With just that minimum, you can make contact with many amateur radio

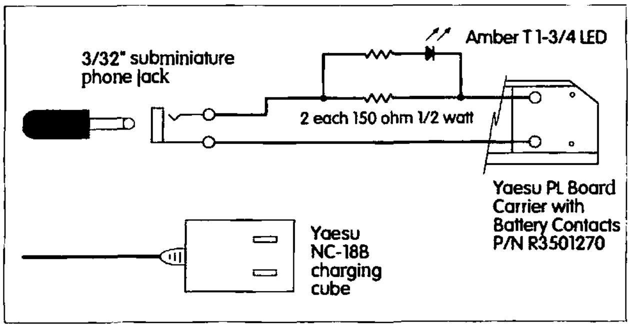

Fig. 4. Schematic diagram of the slip-on FT-209RH charging adapter described in the text.

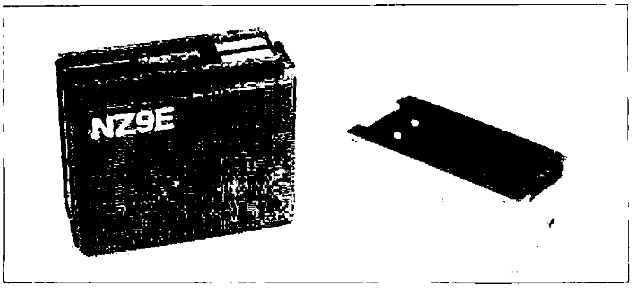

Photo A. *The Yaesu FBA-5 battery pack is shown on the left, the slip-on charging adapter on the right.*

oriented telephone BBSs who welcome ham callers from outside the group of normal users. Check around with local club members, or on your local 2 meter repeater, to find out the phone number of the popular ham telephone BBSs in your area.

One system that I've explored is run by Bill Cohn N9MHT in Schaumburg, Illinois, and operates under the name "The Precision Board." Bill encourages any ham, from anywhere, to call his system at (847) 985-9544, 24 hours a day. When you first sign on, you'll be guided through a few easy-to-answer questions, just to get acquainted. Then, as with many such telephone BBSs, you can quickly download Bill's ALLFILES.ZIP file, sign off, unzip the downloaded file, then browse through the listing offline, to see exactly what specific program files might be of interest to you (the shareware file for unzipping the ZIP file is even available if you don't already have it). You can then call back later to download just those files of specific interest (many are in the zipped format), keeping your telephone charges to a minimum and not occupying the board any longer than needed. The Precision Board is affiliated with the Arlington Communications League (ACL), a suburban Chicago ham radio club, and has hundreds and hundreds of files (programs) dealing with amateur radio, as well as general computing utilities and games. Some of the programs are Freeware (no strings attached), others are Shareware (where the user is encouraged to pay for the use of the program after a free trial period, if you like the program and plan to use it regularly).

It's also a good idea not to just "take" from any BBS, but also to "give" a bit back, in the form of uploading interesting programs that you might have that are also of a Freeware or Shareware nature; don't upload commercially purchased software that isn't intended for secondary users. Like a repeater system that you regularly chat on, a telephone BBS SYSOP can always use an extra dollar or two to help with line charges, equipment operating costs and system upgrades.

Remember, these are volunteers who've put up their own gear for our benefit—don't be a rude "guest" in their electronic den. The same courtesy should apply to sysops within the HF/VHF/UHF amateur digital network as well. They're giving their time, energy and equipment for our convenience, in the traditional ham not-for-profit spirit.

Getting wired

From Mike Hall KE4GBE: "Next time you attend a hamfest or computerfest, keep an eye out for someone selling multicolored computer ribbon cabling; it makes great hookup wire for general electronic project construction use. The multicolored ribbon is much simpler to identify, but even the all-gray ribbon cables can be utilized if you mark both ends of the individual wires with tiny dots (1, 2, 3, 4, etc. dots) using a black fine-point felt-tipped marker pen. The flat computer ribbon cable I'm referring to is generally very good quality, stranded, easy to strip and tin, and will make your home-brew projects look much more professional. There is naturally some inter-wire capacitance, but it usually won't have any serious drawbacks in non-critical circuits. I've also seen twisted-pair computer interconnect ribbons that have automatic resistance to inductive coupling from the outside due to their twisted format.

"I'm sure that I'm not the first to 'discover' this tip—even Heathkit used sections of ribbon cables for some of the interchassis wiring in their kit designs—but I simply thought that I'd mention it again in case it's been forgotten or overlooked by some."

Moderator's note: Good suggestion, Mike. Of course the multicolored ribbon cable can also be separated into individual colors for use as regular single-circuit hookup wire when distinctive colors will be helpful in troubleshooting later on. It's a good way to collect a wide variety of short hookup wires of every color imaginable without having to buy long reels of each color.

That wraps up another month of "Ham To Ham." As you've no doubt noticed, I'm still using too many of my own ideas and suggestions in the column—I need more input from all of you if we're to keep on exchanging ideas each month through the pages of *73*. I've mentioned it before, and it's true: This is your chance to express some of the neat and interesting ideas, solutions, tips or suggestions that you've found handy in your ham radio career. Jot them down and send 'em on to me at the address in the above this column—there's a very good chance you'll see them in print here in one of the future issues. You needn't be an "old-timer" to have had worthwhile experiences; I've received a number of good ideas from relative newcomers to our hobby. Often techniques that can apply to ham radio are picked up from your professional experiences on the job, or sometimes they're just inspirational flashes that come when walking through a store or thumbing through a catalog and seeing something that has "good application for the ham shack" written all over it. Amateur radio touches on so many other areas of life's experiences: outdoor structural and wiring techniques, indoor shack and workshop ideas, computer conveniences, test equipment shortcuts, and on and on. Whatever you've experienced that you believe would be helpful to others is fair game; send it in and let me see what you've thought of. I'll be sitting out by the mailbox, and it's kind of cold this time of year, so don't let me down!

And as always, many thanks to those who've contributed to this month's column:

Always use your own best judgment before modifying any electronic item from the original equipment manufacturer's specifications. No responsibility is implied by the moderator or *73* for any equipment damage or malfunction resulting from information supplied in this column.

Please send all correspondence relating to this column to *73's* Ham To Ham Column, c/o Dave Miller NZ9E, 7462 Lawler Avenue, Niles IL 60714-3108, USA. All contributions used in this column will be reimbursed by a contributor's fee of $10, which includes its exclusive use by *73*. We will attempt to respond to all legitimate contributors' ideas in a timely manner, but be sure to send all specific questions on any particular tip to the originator of the idea, not to this column's moderator nor to *73*.

HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92837

Buckeyes vs. Wolverines

Football season is in full swing and Thanksgiving will soon be here. Unless you live in the Southern Hemisphere, you're in for some colder temperatures and shorter hours of daylight. Will that bring a halt to hidden transmitter hunting in your area? T-hunters in Florida and Southern California have relatively good weather all year long, but you have to be more hardy to go on radio direction finding (RDF) contests in Midwestern states.

Weather doesn't deter the intrepid transmitter trackers of southeast Michigan and northwest Ohio, where "foxhunting" is what they call it. The Toledo Radio Amateur Club holds a mobile hunt each month. "The fox can be anywhere within a 20-mile radius of the University of Toledo," says Vince Vasselo KB8TEP. "All he has to do is get a signal into the repeater. He must either transmit on the repeater input or tell the hunters what frequency the hidden beacon is on. It isn't specified how often he has to transmit; we try to keep it at least every minute or so. Intermittent signals like that tend to encourage people to use their maps. The first finder wins the hunt. Once everyone comes in, we have a drawing for who will be the fox the next month."

Another fan of traditional find-the-foxbox hunts like this is Mark Drolias N8IQX of Dearborn, a suburb of Detroit. "We have had many cleverly disguised beacon hunts," he says. "Guys have built camouflage electrical utility boxes and hung them on telephone poles, along with conduit cut for the right frequency and wires dangling to make it look like it belonged there. One hooked a windshield wiper motor up to a beam and set it on a tripod in a bunch of weeds, with the beam sweeping back and forth as it transmitted."

Lately, a different type of hunt is gaining popularity in the Motor City area. "We changed our hunting strategy within the last year to keep the hunts moving and to get more in," says Steve Sable N8NYU from Maybee, Michigan. "We now have 'tag' hunts on Saturday nights. The first fox takes off from the starting point in his car and has a half hour to find a good place to hide. He must stay with the vehicle. Once he gets stationed and starts to transmit, we have just a half hour to find him. The first person who finds the fox has a half hour from that point to go find his own place to hide, while the rest of the hunters continue searching for the first one. Once fox #2's half hour is up, his hunt starts, whether everybody has found the first one or not. This goes on for four hours and we usually get in six hunts."

Steve's group, the Radio Active Communications Club, holds tag hunts on the second Saturday of the month, while the Maumee Valley Monitoring Association of Ohio holds tag hunts on the fourth Saturday night. It's about 50 miles from Detroit to Toledo, so it has become a tradition for Detroit area hunters to go to Toledo hunts and vice versa, just like the age-old football migrations. "We get four or five teams on a low day, up to 15 on a good day," says N8IQX. "When my wife and I go down to hunt in Ohio, we don't get back until 1 or 2 a.m., but we work afternoons so it's OK. It's fun, but lots of wear on tires."

Mark prefers the format of tag hunts. "The fox can use any power or polarization," he says. "He can transmit a little or a lot, with any on/off timing. When he sees people in the area, he can stop transmitting for a while if he wants. After the last hunt of the evening, we meet up for some food. Tag hunts are good because a beginner can come out without knowing anything about fox-hunting, and by the end of the night have found several foxes and gotten a good grasp of it. On the other hand, with a beacon hunt, it's over once you find it and you have to wait a month before you can come out and hunt again."

"You have to transmit from your car, but if you throw a tent over it to hide it, that's legal," KB8TEP adds. "We want everyone to stay in their cars because it's safer. If people come out to ride along, we make them handle the gear. Some really take to it.

"Usually our hunts are on 146.565 MHz simplex," Vince continues. "Occasionally, we throw in one or two hunts on one of the 440 MHz repeaters. Some 70 cm repeater owners are real happy that we are interested in doing some hunting on that band. Another time, for a change of pace, the target was mobile and everybody at the start was told to team up and work together to catch him, instead of competing."

Whereas law enforcement personnel are used to seeing vehicles with strange antennas here in Southern California, Midwestern officers are more curious and suspicious. N8NYU says, "Whenever we hide in a city, we try to notify the police department two weeks in advance. People think we're hunting UFOs or seeking signals from burglar alarms, so they call the authorities. A lot of times, we get pulled over and questioned. On our last hunt, the guy who was the fox got stopped. They said they were going to confiscate all his equipment because he had a scanner in his vehicle. We all quickly converged and showed them the scanner laws for Michigan. That got him off."

"People think we're hunting UFOs."

Quads vs. yagis

Expect to see a variety of RDF gear if you go T-hunting in the Toledo/Detroit area. Steve says, "When I started hunting about five years ago, our antennas consisted mainly of PVC pipe frames with copper piping for elements. They were hand-held antennas; we would stop alongside the road to get a fix and then continue on. With time, we graduated to 2- or 4-element cubical quads with active or step attenuators. Quads were made of PVC pipe booms with Fiberglas™ spreaders and telephone wire elements. Then we began to mount these antennas so we would not have to exit the vehicle. Some made mounts to go through sun roofs, but most made brackets to mount the mast through the passenger window."

Steve and his hunting partner, Chris Theisen KK8K, use a Cubex 4-element quad. "We tried a through-the-window mount and that worked, but rainy and windy weather caused problems," says Steve. "Some of our runs to the fox were made at a little above normal speeds, making it difficult to hold onto the assembly. We once snagged the quad on a low hanging branch, which almost lifted Chris from the seat as he hung onto the mast for dear life. That's when I decided a change was in order.

"I built a wooden holder for my truck bed (**Photo A**). A Ford windshield wiper motor is mounted in the bottom center of the frame (**Photo B**). In the center of the crossboard is a bearing around the mast. We found that without it, there was too much binding of wood rubbing against wood. To show beam heading, I drilled a hole all the way through the mast about six inches above the bearing and inserted a clear plastic tube and a lamp, which connects to a 9 volt battery for lighting at night."

Steve controls the motor with a left-right toggle switch in a home-brew box inside the cab. "We found that applying the full 12 volts turns the antenna too fast for tracking," he says. "To drop the voltage and slow the turning,

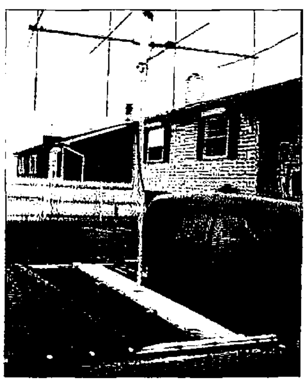

Photo A. N8NYU's motorized quad mounts into the bed of his Chevy pickup with C-clamps. (Photo by Steve Sable N8NYU)

I added a small toggle switch and a series 4.5 ohm 10 watt resistor. Both speeds are useful; high is for checking if the fox signal is 180 degrees out and then low speed is used once you're on the track of the fox signal. With this system, weather is no longer a factor."

Of course N8NYU's setup is a head-turner as well as a beam-turner. "Every time we're in traffic and people pull up next to us, we just sit there straight-faced and sweep the thing back and forth," he says. "Usually, they are still sitting at the light when we take off. If folks have enough courage to inquire, they want to know, 'You guys from the cable company?'"

According to KB8TEP, most Detroit area T-hunters use vertically-polarized quads, while Toledo hunters prefer horizontally-polarized yagis. Vince uses a 3-element yagi, about three feet above the roof. "I seem to have no trouble with cross-polarized signals, even in downtown Toledo," he says. "I guess I am used to them and know what to expect."

Lately, a few hunters in both contingents are trying Doppler RDF sets. When the fox signal is vertically polarized and strong reflected signals are not present, a Doppler does well. "It's all flat out here," Vince says. "So when you are mobile, the Doppler leads you right to it. At the last hunt the first, second, and third place teams were Doppler hunters."

But others disagree, saying that there are enough reflections (multipath) to cause grief to Doppler hunters in many locations, especially if the signal source is horizontally polarized, as it can be in the Toledo hunts. "The Dopplers still find the transmitter," says N8IQX. "But they have not come in first on hunts like that. Users can tell when it's horizontal, they say the signal is more 'wavy' sounding."

When you hunt with the Doppler, you lose that feel for how far away you are," KB8TEP adds. "I compensate for that by keeping an extra receiver with the antenna off in the car to tell when I get close. It helps, because sometimes you go another block and it goes away, so you know you went too far. Some of the guys feel they have some other tricks that will mess up the Dopplers. It will be interesting to find out if they do or not when they get to be the fox."

Jammers beware

Training and practice from the friendly RDF contests are helping keep the air waves in both cities clean. KB8TEP says that Toledo hams have established an interference committee through ARRL, but most of the QRM they have found has been accidental. "I have gone after two stuck transmitters," Vince says. "One fellow had been talking to someone in his shack and set his clipboard down. It keyed the mike of his HT connected to his antenna. I happened to notice the dead carrier, called up Tony Everhardt N8WAC and we went out. My car was in the shop that night so I had to do it with my wife's car and a handie-talkie. We triangulated, found the house, checked the front and behind, and saw the antenna up there, but we didn't know who it was. We ended up with three hams at the scene, so one stayed out on the road and two of us walked up to the door. It turned out to be a ham and he thanked us profusely.

"Another time, someone keyed down solid on a packet frequency," Vince continues. "I got a call from the BBS sysop and we tracked it to a house. We had four cars parked across the street and a woman walked out. We asked if there was an amateur radio set in the house and she said her son was a ham. Then she went back and as we were listening, we heard a jumble of things being moved around and wires being pulled, then the signal quit."

N8IQX is the ARRL Official Observer Coordinator for Michigan, where malicious activities are more common. He says, "Every time I have done a talk at a club, I tell them that if they have a foxhunt group on their repeater, they will have the quietest repeater in town.

"When we first put our RDF crew together, we tracked someone who was jamming the weather net," Mark recalls. "And last year we may have caught a security guard at a retail outlet. A lot of jamming was going on and we got a heading into this parking lot. We saw the guard look at us, then everything stopped and we never heard it again.

"A police department about 50 miles west of Detroit lost a handheld two years ago. Then someone began jamming a paramedic frequency, starting every evening after school. A friend of mine got wind of it and we went out. By nightfall, we had determined which part of the city it was in. A few people returned the next day and zeroed in on the house. The police realized at this point who it was, a problem kid. They went to talk to his father at work and the dad said, 'Let's go home and look.' They found the unit in the house, along with a bunch of stolen cellular phones. The neat thing was that the battery was dying on the handheld, but we were still able to get enough signal to pin it down to the house."

Not only do the Buckeye and Wolverine T-hunt groups like to have joint hunts, they want to hunt over a wider area together. According to N8IQX, "At least once a year we would like to do an all-day hunt for the entire Midwest. Beacons would be hidden around a large area, both metropolitan territory and some woods. We want to promote it enough to get hunters from Michigan, Ohio, Indiana, Illinois, Wisconsin, and Kentucky."

The first attempt at such a wide area hunt took place this spring. N8IQX says they picked the last weekend of April, which had been the weekend of the Dayton HamVention in years past. He would like to make it an annual event on that weekend, now that the HamVention has moved to mid-May. KB8TEP enjoyed that hunt. "We had a couple fixed beacons and then we went into tag hunts after that," he says. "It went really well, though we didn't have many people from outside our area."

You, too?

This column begins the ninth year of "Homing In" in *73 Magazine*. There has been no shortage of things to cover in the world of RDF during that time. More and more readers are discovering the fun of both mobile T-hunting and international-style radio-orienteering. Hams are increasing the use of RDF skills for public service and for self-policing.

There is a good chance that a club near you is now holding hunts and you could be involved. Check the "Homing In" site on the World Wide Web for lots of local T-hunting links and E-mail correspondents like N8NYU (ssable@foxberry.net) for Detroit and KB8TEP (vincev@juno.com) for Toledo. There are 31 local contacts on my site as I write this. No doubt there will be lots more by the time you read it. Point your browser to http://members.aol.com/homingin/ and leave me an E-mail note while you're there.

In the coming months, I'll have some new RDF projects and reviews of new commercial RDF gear, including a new microprocessor-based Doppler set that is getting a thorough checkout in my van right now. Let me know what RDF topics you would like "Homing In" to cover. Write to the address atop this column, or send E-mail to Homingin@aol.com.

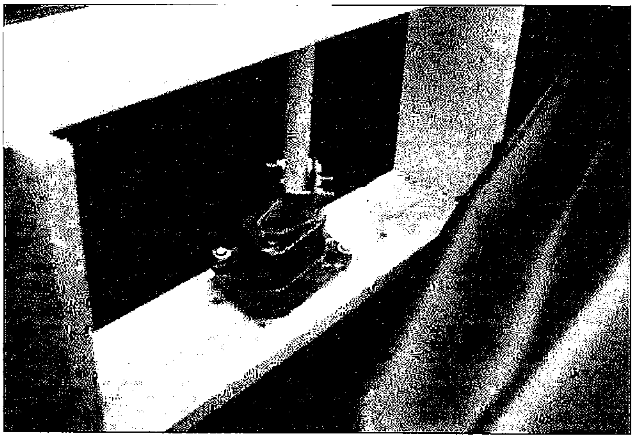

Photo B. *A Ford windshield wiper motor turns N8NYU's mast. Steve says it is important to use the matching Ford bracket to attach the mast to the motor. (Photo by Steve Sable N8NYU)*

HAMS WITH CLASS

Carole Perry WB2MGP
Media Mentors Inc.
P.O. Box 131646
Staten Island NY 10313-0006

Preparing to prepare the class

The start of the new fall term brings with it all the usual "teacher-type stuff" that one has to do in order to get the school year off to a good start. After more than 18 years of teaching, I am still amazed at the enormous amount of preparation that has to go into laying a solid foundation for the school year. There should definitely be a course in the teacher methodology programs in college on "The Value of Preparedness."

After the class and I discuss the appropriate rules of behavior at our ham shack, and the children are all excited about speaking on the air, I always notice a few of them looking a bit apprehensive. I've developed the perfect thing to introduce at this time. I will say something like, "Probably a few of you are worried that you won't know what to say to the person you will meet on the air." Inevitably, I will then see knowing nods and smiles, as though I've just read their minds. I can almost hear a collective sigh of relief as I pass out a list of questions for them.

"Never ask anything that can be easily answered with a 'yes' or 'no' response."

Use questions

Over the many years of teaching ham radio to 6th, 7th, and 8th graders, I've come up with a list of pivotal questions for the children to use to help them develop some interesting conversations with different folks they will encounter on the air. Obviously, the questions have to be modified according to the background and age of the other person. But it gives my kids a place to start. They feel comfortable holding a sheet of questions in front of them at the beginning. After the second or third time, most of the kids don't need the list. It's a good ice-breaker!

First, the children write out their first names phonetically. Everyone loves to do this. They write out their own background information, like names of brothers and sisters, where they've lived before coming to New York, what their hobbies are, what their favorite school subject is, what singing groups they like, what sports they're interested in, and so on. Now they know they can always fall back on these things in the conversation.

When it comes to asking questions, I tell them never to ask anything that can be easily answered with a "yes" or "no" response. Why not take advantage of this wonderful "live" resource we have? When speaking with other children I like my kids to learn about the differences between their schools in different parts of the country. Are they studying the same things? How much homework do they get? How's their cafeteria food? Most importantly, I list questions that will show how much they have in common with other children. No matter where a child may be from, they all dread tests and report cards, no one likes homework, and all kids like to complain about teachers and too much work.

When speaking to adults, a good question is, "What do you do (or what did you do) for a living?" The children can then ask the other person to describe their workday. What role did ham radio play in the career choice? Is this a good job choice for a young person to consider?

Where are you talking to us from? This question often leads to fascinating responses ... everything from submarines, airplanes, bicycles, motorbikes, boats, to beaches, lighthouses, the Pentagon, the United Nations, the Johnson Space Center, and on and on. Most hams like to share with the children what influenced them to get into the hobby. A good question to follow up with is, "What's the most memorable, or funny, or exciting, or unusual contact you've ever had?"

If you brainstorm with your classes when making up the question list, you will be sure to get some interesting responses. A good classroom discussion can always follow an "inappropriate" question. It's important to teach children that when something offends another person, or invades their privacy, then it stops being fun. This is a hobby to be enjoyed by the participants. In my opinion, discussions about political beliefs or religious principles are better saved for other venues. Respect for other people, being open-minded about differences amongst people, and having an inquiring mind are all side perks that come with the teaching of ham radio to young people.

The importance of being prepared yourself for a lesson is obvious to a good teacher. The importance of passing that technique on to your students is even more important. Have fun!

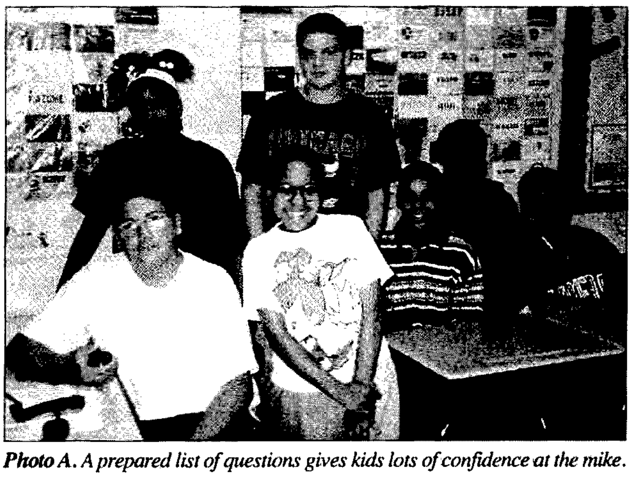

Photo A. A prepared list of questions gives kids lots of confidence at the mike.

Ham Radio Fun

Communications Simplified, Part 11

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

The superheterodyne receiver, described in the previous installment, is the cornerstone of modern electronics. The superhet is used in car radios, hi-fi receivers, TV sets, cordless and cellular phones, and even radar detectors. Although the basic block diagram of a superhet is the same regardless of the kind of receiver, there are still quite a few differences between different receivers. We have already looked at some of these differences, such as double-conversion or using a converter instead of separate mixer and oscillator. Let's look at some others.

RF frequency range

Different receivers tune in different ranges of radio frequency signals. For example, a commercial AM radio will tune from 550 to 1650 kHz, while an FM radio will tune from 88 to 108 MHz; a TV set will receive signals between 54 MHz and about 850 MHz, while a radar detector will receive signals around 10 GHz. Thus, the actual circuitry will be different as well. Depending on the frequency range, the antenna will be different, the RF amplifiers and mixers will be different, and even the oscillator must be different.

AM broadcast signal strengths tend to be higher, and so AM broadcast radios usually don't have an RF amplifier (except in car radios), while an FM radio will almost certainly have one. This is usually a cost issue, but there are often technical reasons as well. For example, radar detectors do not have an RF amplifier because amplifying RF signals at radar frequencies is just too expensive. High frequency communications receivers, on the other hand, almost always have an RF amplifier stage—sometimes they even have two.

Selectivity

The required selectivity depends on the bandwidth of the signal. Selectivities often range from just a few hundred hertz (for receivers designed for receiving Morse code or slow-speed digital signals) to 6 MHz (for a TV receiver).

The proper selectivity is often obtained with several tuned circuits tuned to the IF frequency, often with double-conversion to provide lower selectivity without having image problems (see the previous part of this series). But other kinds of filters are also used sometimes, such as ceramic or crystal resonators, or SAW (Surface Acoustic Wave) filters. These kinds of filters use mechanical rather than electrical resonance, to provide a narrower bandpass. But more important, they provide a more stable and repeatable response without having to be individually adjusted.

"But more important, they provide a more stable and repeatable response without having to be individually adjusted."

Stability

They say that a good politician is one who, once bought, stays bought. The same is true of receivers—once a receiver is tuned to a station, it should stay tuned to it. When it does, we say that it is stable; when it doesn't, then we say that it *drifts*.

In a superheterodyne receiver, stability is most affected by the oscillator. In general, oscillator stability is most of a problem when the carrier frequency is high but the bandwidth is small. In this case, even a small percentage change of the oscillator frequency can cause the signal bandwidth to be different from the passband of the receiver.

For broadcast AM receivers, stability is not much of a problem, except perhaps in car radios whose temperature may change tremendously from the time you start driving on a cold day until the heater warms up the entire area under and around the dashboard.

Oscillator drift at higher frequencies is much more of a problem, and so the FM radio's oscillator will probably be quite different. Oscillators in AM radios tend to be spread out on a printed circuit board, while oscillators in FM radios will be very compact, and may even be enclosed in a shielded metal case to prevent outside conditions from affecting the circuit. An automatic frequency control (AFC) circuit (described later) may be used to keep the frequency constant. The AM radio will probably use a converter, whereas the FM radio will most likely use a separate oscillator and mixer.

Another difference lies in the detectors—an AM radio may contain a simple diode to rectify and demodulate the carrier, while an FM radio might use a Foster-Seeley discriminator or some other type of FM detector.

Since the bandwidths of AM and FM signals are different, the IF frequencies will be different. AM radios tend to use a 455 kHz IF (frequencies between 250 and 500 kHz are also sometimes used), while the FM radio will probably use 10.7 MHz.

AM/FM radios will use a combination of the above. Most such radios have completely separate RF and mixer/converter sections for each band, but use a common IF section for both. They do this by connecting a 455 kHz IF transformer in series with a 10.7 MHz IF transformer, and using the same transistor to amplify both. There will be separate AM and FM detectors, but then a common audio amplifier for both. There is obviously an art to getting the most performance from the least number of components.

Once you leave the simple, inexpensive AM and FM broadcast receiver and go either to a more expensive hi-fi or car stereo set, or to the type of receiver used in communications (amateur as well as commercial), then new circuits and options come into play. The rest of this section describes some of these.

Types of oscillators

Some radios (such as the typical home broadcast receiver) are frequently retuned from one station to another; others (like taxicab or oil truck radios) may stay tuned to one particular frequency their entire life. Thus, the oscillator in one radio may be tunable, while the oscillator in another radio may be fixed on one frequency for years. Oscillator design is therefore an important part of the whole design.

Inexpensive radios (such as pocket transistor radios) generally use simple LC oscillators; the frequency is set by an inductor and capacitor. Since components tend to change size and value as the temperature changes, special temperature-compensating capacitors are often used to try to keep the oscillator frequency constant. Even so, many FM radios need an AFC or Automatic Frequency Control circuit to keep the radio in tune because otherwise the LC oscillator would still drift.

Single-frequency radios, on the other hand, generally use *crystals* to set the oscillator frequency. As shown in **Fig. 1**, a crystal is a small piece of quartz, roughly the size of a dime. It has a plated area on each side, and is clamped in its holder between two thin spring-like wires. Because it is only held on its edges, it is free to vibrate.

Quartz is the same piezo-electric material we discussed at the beginning of this series. It converts between electricity and motion: When you bend it, it generates a voltage; if you connect a voltage to it, it bends. In this case, the small disk of quartz has a natural resonant frequency, typically in the range of 0.1 to 25 or so MHz, depending on its size. If you connect it in the feedback path of an amplifier, the amplifier starts to oscillate at the resonant frequency of the crystal. This frequency is very stable, and remains constant (within a tiny fraction of a percent) over a long time.

Crystals must be ordered for the specific frequency you need. Some frequencies (such as the 3.579545 MHz color-burst frequency in a TV set) are used so often that the crystals are mass-produced in huge quantities and cost less than $1 each; crystals for other frequencies may have to be individually made at substantially greater cost.

"These crystals are often (wrongly) called third-overtone crystals."

You may remember that we said crystals typically resonate in the range of 0.1 to 25 MHz or so, whereas the first oscillator in many radios may need to oscillate at much higher frequencies. A higher frequency can be produced in one of several ways.

A typical case might be an amateur radio which needs a first oscillator frequency of 136.24 MHz. This is usually done by using a crystal around 15 MHz, which oscillates on its third harmonic of 45.41333 MHz. Instead of oscillating in one piece, the crystal oscillates in one-third sections at approximately three times its fundamental frequency. This is its third harmonic, which should properly be called its second overtone, but these crystals are often (wrongly) called third-overtone crystals.

Once the crystal generates the 45.41333 MHz signal. A *tripler circuit* then multiplies the frequency by three to make the required 136.24 MHz. A tripler circuit is an amplifier which purposely distorts the signal to produce harmonics; a tuned circuit in the output then selects the third harmonic and deletes the rest. (A doubler would be tuned to the second harmonic; although it is possible to build quadruplers, quintuplers, etc., this is seldom done because of technical problems. Instead, combinations of doublers and triplers are usually used.)

Since crystals have a fairly limited range of frequencies, it is common to use chains of doublers and triplers to multiply the frequencies up to what is needed, or else use digital dividers (flip-flops) to divide the frequency down to a lower value.

Multiplying frequencies up to a higher value by using doublers and triplers is easy for certain values. For example, multiplying a frequency by 12 is easily done with a tripler and two doublers (since 3x2x2=12), but multiplying by 11 or 13, or most other numbers, cannot be done with doublers and triplers. Instead, we use a phase-locked loop (described shortly).

AGC, AVC, AFC, and BFO

This alphabet soup describes a few other circuits often found in receivers. The *automatic volume control* (AVC) or *automatic gain control* (AGC) circuits are basically the same. In each, the output of the detector is sampled to determine how strong a station is. On strong

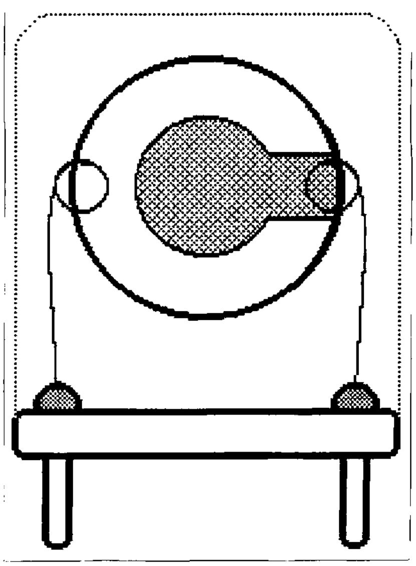

Fig. 1. A quartz crystal.

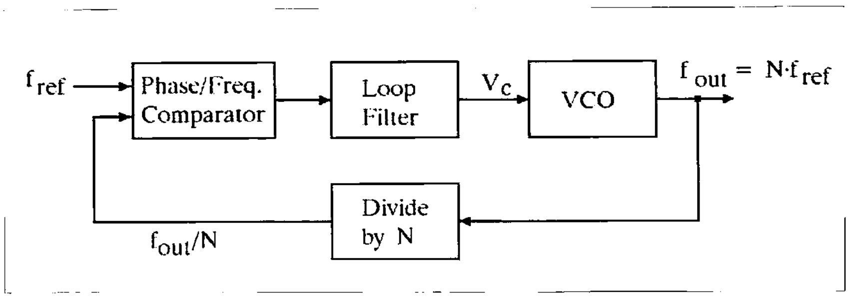

Fig. 2. Block diagram of a phase-locked loop.

stations, this circuit lowers the gain of the IF amplifier, while on weak stations, this circuit increases the gain. Since strong signals are amplified less while weak signals are amplified more, the result is to make both strong and weak signals sound the same.

An *automatic frequency control* (AFC) circuit is used in those FM receivers whose oscillators tend to drift in frequency. While modern receivers with phase-locked loop oscillators don't need the AFC circuit, almost all other oscillator circuits tend to drift and therefore can use AFC. The AFC circuit checks the received signal at the detector to see whether the radio is correctly tuned to the station. If it's not, then it sends a correction signal back to the oscillator, forcing it to either increase or lower its frequency to bring the station back into perfect tune.

The *beat frequency oscillator* (BFO) is used in some older receivers to receive Morse code and DSB or SSB transmissions. When receiving a DSB or SSB signal, the BFO supplies the missing carrier that is needed to go with the sideband(s). When receiving Morse code (called a *Continuous Wave* or CW signal), the BFO supplies a continuous signal near the IF frequency, which beats with the received carrier to produce an audio tone; this is what the operator hears and decodes from Morse code into text.

The PLL (phase-locked loop)

The PLL or *phase-locked loop* is a fairly recent development in electronics. One of its uses is to multiply crystal frequencies by unusual numbers; it has the stability and accuracy of a crystal oscillator but, unlike a crystal, it is tunable.

As **Fig. 2** shows, the PLL circuit looks like a traditional servo loop circuit. Its output comes from a VCO or *voltage-controlled oscillator*. This oscillator generates the frequency we want, but instead of the frequency being controlled by a knob or control of some sort, it is controlled by an input voltage V_c. The VCO can oscillate over a wide range of frequencies, and V_c tells it what frequency to output. Usually, if V_c is high, the output frequency is high, while if V_c is low, the output frequency is low.

Besides going to the output, the f_{out} signal also goes through a digital circuit which divides its frequency by some integer *N*. *N* is usually a variable number, which can be dialed in from some front-panel control, or perhaps is set by a small computer chip in the radio.

The output from the divider circuit is a feedback signal, which now has a frequency f_{out}/N. It is sent back to a *phase/frequency comparator*, which also receives an input reference signal whose frequency is f_{ref}. The comparator looks at the two inputs, and compares their frequencies. If the frequency of the signal coming back through the divider is lower than the input signal f_{ref}, then the comparator sends out an error signal which goes through the loop filter to the VCO and tells the VCO "raise your frequency, it is too low." The VCO frequency then goes up, which raises both f_{out} and the feedback signal to the point where the two inputs into the comparator match. (Of course, if the feedback signal was too high in frequency, the comparator would tell the VCO to lower it.) In this way, the PLL varies the VCO frequency up and down so it can lock it at the value that makes the two inputs into the comparator equal. When this happens, we say that the loop is *locked*.

In operation, the f_{ref} input signal usually comes from a crystal oscillator, and is very stable. Since the digital divider circuit divides by a number *N* which is also exact (it is an exact integer), the output signal f_{out} is exactly equal to $N \times f_{ref}$, and is therefore also very stable.

The secret of the system lies in the divide-by-*N* circuit. This is a digital circuit which, with just minor changes, can divide by many different values of *N*, and each different *N* produces a different output frequency.

For example, suppose you needed an oscillator tunable to any exact point between 10 and 20 MHz. It would be almost impossible to get that sort of accuracy from an LC oscillator, and it would be very expensive to use 10 different crystals, one for each frequency. Instead, you could use a PLL with a 1 MHz crystal, and a divider which can divide by any integer between 10 and 20. If the crystal was accurate to, say, ±0.001%, then the output frequencies would be just as accurate. A PLL used like this to generate many different output frequencies is called a *frequency synthesizer*.

Phase-locked loops are very common today. If you have a car radio with a digital readout, it most likely uses a PLL to set the exact receive frequency. Before PLLs, a six-channel walkie-talkie needed six crystals for the receiver, and another six for the transmitter, just to set the frequencies; modern synthesized walkie-talkies can access hundreds of transmit and receive frequencies with just two or three crystals.

"The secret of the system lies in the divide-by-*N *circuit."

Before we leave phase-locked loops, we should mention a few other uses.

One use is as an FM detector. Suppose we replace the divide-by-*N* circuit with a plain wire (which makes *N* equal to 1, so the output frequency is the same as the input reference frequency). Further, let the f_{ref} signal, rather than being a very stable reference signal, be an FM modulated signal (perhaps coming from the IF amplifier in a receiver). As the signal frequency deviates back and forth, the PLL will keep the loop locked, forcing the VCO frequency to vary up and down in step with the input signal. The V_c signal going into the VCO tells the VCO what it has to do to match the input frequency change. In other words, the V_c signal goes up and down with the frequency—it is the demodulated output.

The PLL has one very useful characteristic: Given enough time, it can lock onto an input reference signal, even if that signal is buried in noise. It is therefore an excellent circuit for detecting very weak signals. Furthermore, since the VCO output frequency is the same as the input frequency—but without the noise— the PLL can be used to "clean up" noisy signals. The disadvantage, however, lies in the words "given enough time." The more noise there is in the input signal, the slower the PLL will lock up; hence, the signal must deviate slowly or the PLL will unlock and lose it.

Direct digital synthesis

Direct digital synthesis is a newer way of generating adjustable, yet very precise, frequencies. This approach has only become practical in the last few years, with the arrival of some very fast integrated circuits.

Fig. 3 shows the idea. The top waveform in the figure shows a typical sine wave you might want to generate. The first step is to take some very careful measurements of the height of the wave. For example, at the very left, we show an amplitude of 0 volts. A bit further on, the wave has a height of 0.174 volts. A bit farther on, the height is 0.342 volts, and so on. You do this for the entire length of one cycle.

The next step is to build a digital circuit that stores these measurements as binary numbers, and that can output them at high speed. The trick is to control the output speed so that the measurements come out at the exact instant when the wave should be at that amplitude. For example, if you took 10 measurements of the sine wave, and wanted an output of 1 MHz, then you would need 10 x 1,000,000, or 10,000,000 numbers to be output in exactly one second. You can see why this requires some very fast circuitry.

Once you have this digital circuit, which is spitting out numbers at a very fast rate, telling you how high the wave should be at any particular instant, you need to convert those numbers back into voltages. This is done with a *digital-to-analog converter*, which accepts the digital numbers and converts them into analog voltage.

Since the digital numbers represent specific points on the curve, and not the full sine wave itself, the output is the lower curve shown in **Fig. 3.** While this sort of looks like a sine wave, it has a lot of steps in it which represent the missing data. Fortunately, these steps represent high frequency signals which are easily removed with a low-pass filter, giving us a sine wave again.

An interesting article in the August 1993 issue of *73* showed how to use the Harris HSP45102DC direct digital synthesizer IC to build the "Julieboard" transceiver. The Harris IC is the digital IC which outputs the digital values for the sine wave; you just tell it the frequency you want, and it outputs the values at just the right rate to put the frequency right on the dot.

Subcarriers

A subcarrier is a carrier which is carried on top of another carrier. Here is an example of a common use: Suppose you have some music, such as what I call elevator music, which you'd like to broadcast to paying customers in a city. But you don't want to spend money to build a broadcast station; moreover, you don't want the music to be interrupted by commercials or even station call letters. You also don't want the public to hear this music for free, because you want to charge your customers for providing them with commercial-free background music for their stores or buildings.

For this application hi-fi music isn't needed, so let's suppose that the music has a frequency range up to perhaps 5 kHz or so. So you amplitude modulate it onto a carrier of, say, 91 kHz. The result is a 91 kHz carrier with sidebands extending from around 86 kHz up to about 96 kHz. These frequencies are well above human hearing, but still too low to efficiently transmit over the air—the antenna would be too long.

You therefore make a deal with a local FM broadcast station to transmit this signal for you. Because your carrier frequency is well above the range that the ear can hear, they can mix it into their audio signal without their own listeners being able to hear it. So we now have a main carrier (the FM station's carrier between 88 and 108 MHz) which carries both the regular FM station's signal, as well as your carrier signal, which occupies 86 to 96 kHz. Your carrier is now a *subcarrier*, riding on top of another carrier.

The system just described is actually quite common; FM stations call it an SCA subcarrier, and may use it not just for background music, but also for foreign-language programs, paging signals, or even digital data such as stock market prices. Another example is the color subcarrier in a TV signal; this is a 3.579545 MHz subcarrier, riding on top of a standard TV signal, that carries the color information.

Stereo FM

Stereo FM is another example of how a subcarrier is used to carry additional information on an FM signal, but it is a bit more complicated than the plain SCA approach. **Fig. 4** shows one way to do this. (Actually, **Fig. 4** shows how this was done in early stereo transmitters; modern transmitters use a digital approach called TDM, but its explanation will have to wait until a later section.)

The signals from the left and right microphones of a stereo signal are amplified by two audio frequency (AF) amplifiers, and sent to a *matrixing circuit* consisting of four resistors. Resistors R1 and R2 take the left and right signals (called L and R in the figure) and mix them into a signal called L+R. This *sum* signal combines the left and right signals into one for those listeners who have a mono rather than a stereo receiver. These listeners therefore get all audio, though both the left and right channels play through a common channel.

At the same time, an inverter takes the R signal and inverts it into a signal called -R. Resistors R3 and R4 combine this with the left signal into the L-R signal. This *difference* signal represents only the difference between the left and right channels. For example,

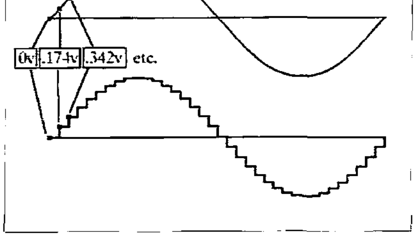

Fig. 3. Digital synthesis of a sine wave.

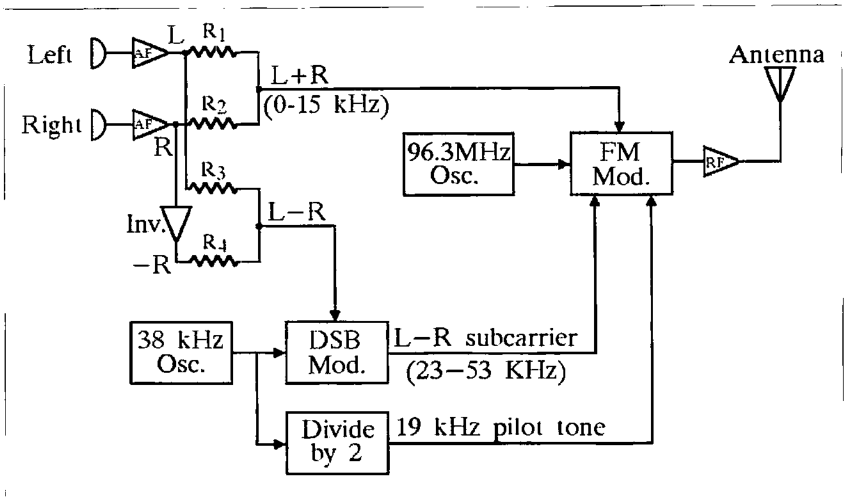

Fig. 4. An FM stereo transmitter.

if a singer is picked up equally by the left and right mikes, the two signals will cancel out (since the R signal is inverted) and not appear in the L-R signal. Instruments at the left or right, on the other hand, will appear mainly in one channel or the other, and so will not cancel out.

The L-R signal is modulated onto a 38 kHz subcarrier in a double-sideband (DSB) modulator. If the audio extends from about 0 to about 15 kHz, then the sidebands will extend ±15 kHz out from the subcarrier, or from about 23 kHz to about 53 kHz.

At the same time, the 38 kHz carrier signal is divided by 2, to produce a 19 kHz signal called the *pilot tone*. This signal is exactly 1/2 the frequency of the 38 kHz carrier.

All three of these signals—the main L+R audio signal, the DSB L-R subcarrier, and the pilot tone—are fed to the main FM modulator, which modulates all three of these onto the main FM station carrier (shown as 96.3 MHz in this example.) The 38 kHz subcarrier (or actually, its upper and lower sidebands, since the carrier itself is not there) therefore becomes a subcarrier on the main carrier. **Fig. 5** shows the resulting spectrum, which looks like this:

- •Main L+R signal , up to 15 kHz
- •Pilot tone, 19 kHz
- •L-R lower sideband, 23 to 38 kHz
- •Missing carrier (not shown), 38 kHz
- •L-R upper sideband, 38 to 53 kHz
- •Room for possible SCA subcarriers, from 53 to 100 kHz

With signals extending up to a possible 100 kHz, the overall bandwidth of the FM signal can be up to 200 kHz.

Why is the subcarrier DSB rather than plain AM or FM? For two reasons. First, it is not FM because an FM subcarrier at any reasonable modulation index would have an excessive bandwidth: it would extend down below 23 kHz, and start to interfere with the main L+R channel. And it is not AM because that would increase overall noise. Remember that each time a subcarrier is added to the main carrier the volume level of the main signal (the L+R signal in this case) has to be reduced to prevent the overall signal from being over-modulated. By omitting the subcarrier itself, and including only its sidebands, less reduction of the main signal is needed. This provides a louder, less noisy signal to listeners far away from the transmitter.

But, as we mentioned in a previous installment, DSB is not normally used for transmitting music or high quality audio since it is too difficult to re-insert the carrier exactly halfway between the two sidebands. This is where the 19 kHz pilot tone comes in—the receiver will double its frequency to 38 kHz, exactly midway between the two DSB sidebands. The pilot tone is transmitted at a very low level, just strong enough so it can be separated out and its frequency doubled. In this way, the pilot tone helps the receiver provide a carrier at exactly the right frequency, so that the DSB signal can provide good quality audio after all.

Once the receiver demodulates the L-R signal, it uses another matrixing circuit to mix the L+R and L-R signals and produce the pure left (L) and right (R) signals. This is usually shown with the following equations:

(L+R) + (L-R) = 2L (pure left)
and
(L+R) - (L-R) = 2R (pure right)

This rather complex approach to stereo has two inherent advantages. First, the L+R main signal provides a compatible signal for listeners with mono receivers; compatibility was a very important criterion when the FCC decided on this stereo system. Second, The L-R signal is somewhat more prone to noise pickup than the L+R signal; since it is mixed equally into both the left and right channels, the noise comes equally out of both channels. This is more acceptable to listeners than having one good channel and one bad channel. And if the noise does become too high for comfort, the user can always switch the receiver back to mono mode; the radio then receives only the L+R signal, which avoids the noise of the L-R signal.

Incidentally, in addition to the stereo subcarrier, FM broadcast stations can also have one or two SCA subcarriers. Though adding all these signals does reduce the overall signal-to-noise of the station, the economics of charging extra for SCA channels does make it attractive to many stations.

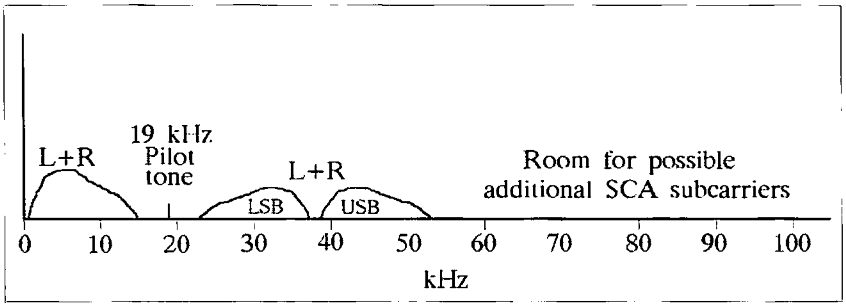

Fig. 5. Stereo FM spectrum.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the February issue, we should receive it by November 30. Provide a clear, concise summary of the essential details about your Special Event.

OCT 26

HOLLAND, MI The Holland ARC will sponsor the Lakeshore Hamfest and Computer Expo, 8 AM-1 PM, at the Holland Christian H.S. Vendor set up Fri., Oct 25th, 6 PM-9 PM. To reserve tables, call *(616) 772-0367*, or mail to *Hamfest, c/o Peter Venlet, 536 Huizenga St., Zeeland MI 49464-1423*. VE Exams will be available. Talk-in on 147.060 and w/ 94.8 pi.

MONTREAL, QUEBEC The Montreal South Shore ARC will hold its annual Hamfest at Place Desaulniers, 1023 Taschereau Blvd., Longueuil PQ. Set up Sat., 6 AM-9 AM. Open to the public 9 AM-3 PM. Wheelchair accessible. Talk-in on 145.390(-). Contact *Francois Drien VE2FDA, 160, Rolland Crescent, Greenfield Park PQ, Canada J4V 2Y2. Tel. (514) 672-9994; Fax: (514) 672-9361. E-mail: fradrien@ulix.net. Packet: VE2FDA@VE2RKY.#MTL.PQ.CAN.NOAM.* Visit the Hamfest WEB page: *http://www.cam.org/~pfisch/hamfest.html.*

NOV 1

FEEDING HILLS, MA The Hampden County Radio Assn. will hold its annual Auction at the Feeding Hills Congregational Church on North Westfield St. (next to the intersection of Route 187 and Route 57). Items are limited to amateur radio, electronics, or computer. Doors open at 6:45 PM. The Auction begins at 7:30. Free admission. The H.C.R.A. retains 10% (up to a maximum of $10). For complete rules or directions, contact *Steve WA1EYF, (413) 596-6216 before 10 PM.*

NOV 2

ENID, OK The Enid ARC Hamfest will be held 8 AM-5 PM in the Hoover Bldg. at Garfield County Fairgrounds. Talk-in on 145.290 or 444.400. VE Exams by W5YI at 1 PM. Contact *Fred N5QXJ, Tom N5LWT, Dick N5HEL, or Jeff N5UBY at EnidARC@AOL.COM:* or write to *Enid Amateur Radio Club, P.O. Box 261, Enid OK 73702.*

NOV 3

KAUKAUNA, WI The Fox Cities ARC annual Hamfest will be held at the Starlite Club, corners of Hwy. 55 and Cty. Rd. JJ. Reg. for VE Exams starts at 8 AM, testing starts at 9 AM. No walk-ins after 9 AM. Bring original license plus 2 copies, and a photo ID. For exam info contact *Larry Siebers KD9IA, (414) 757-1167.* Talk-in on 146.52 simplex or 146.76 Rptr.

NOV 9

HERSHEY, PA A Special Event will be hosted by the Central PA Rptr. Assn. at Hershey Armory, off 422. For details contact *Harold Baer KE3TM, 619 W. 2nd St., Hummelstown PA 17036; Tel. (717) 566-8895.* Ask about VE Exams.

MONTGOMERY AL The Montgomery ARC will host the 19th annual Montgomery Hamfest and Computer Show, in Garrett Coliseum at the South Alabama State Fairgrounds on Federal Dr. Flea Market set up 3 PM-8 PM Fri., Nov. 8th, and 6 AM-7:30 AM, Sat., Nov 9th. Doors open to the public 8 AM-3 PM CST. VE Exams on-site beginning at 8 AM. Bring original and a copy of your current license, picture ID, and $3.00. Talk-in on 146.24/.84 W4AP. Rag-chew on 146.32/.92 (with phone patch ±), 147.78/.18, 449.50/444.50. Flea Market reservations are encouraged. Nearest lodging at Coliseum Inn across the street; call *(334) 265-0586* or *1-800-876-6835*. For info or reservations, contact *Hamfest Committee, c/o 2141 Edinburgh Dr., Montgomery AL 36116-1313;* or phone *Phil at (334) 272-7980 after 5 PM. Fax: (334) 365-0558; E-mail: WB4OZN@worldnet.att.net.*

MYRTLE BEACH, SC The Grand Strand ARC Hamfest will be held 9 AM-4 PM at Myrtle Beach H.S. Talk-in on 147.120. For info, contact *Matt McGuire KF4AIT, (803) 215-0474;* or *David Berry KE4OOW, (803) 248-9401.*

NOV 10

BRANFORD, CT The SouthCentral CT ARA will hold its 17th annual Flea Market at the Branford Intermediate School, 185 Damascus Rd. Sellers 7 AM, buyers 9 AM. Wheelchair accessible. VE Exams. Talk-in on 146.01/.61. Reservations by mail only, no later than Nov. 1st: SASE to *SCARA, P.O. Box 705, Branford CT 06405-0705.* For info call *(203) 483-0856, 24 hrs.*

NOV 17

BENSON, NC The Johnston ARS, Inc., will hold "JARSFEST96" 8 AM-4 PM at the American Legion Complex on Hwy. 301 N. For info contact *Bill Lambert AK4H, 8917 Hwy. 50 N., Benson NC 27504. Tel. (919) 894-3352, eves. 7 PM-10 PM.*

NOV 30

EVANSVILLE, IN The 4th annual E.A.R.S. Evansville Winter Hamfest will be held 8 AM-2 PM (Central time) at Vanderburgh County Fairgrounds. Set up at 6 AM. Contact *Neil WB9VPG at (812) 479-5741; or write to EARS, 1506 S. Parker Dr., Evansville IN 47714; or E-mail EARSHAMaol.com.* The Hamfest Web Site is *http://users.aol.com/earsham/earsham.html. Talk-in on* EARS wide area Rptr Network 145.150(-) Evansville/146.925(-) Vincennes. Alternate: EARS Rptr. 145.110(-).

LITCHFIELD, IL The Central Illinois/St. Louis Area ATV Club will hold their 10th Annual Banquet at the Ariston Restaurant In Litchfield, beginning with a Happy Hour at 5 PM and Dinner at 6:30 PM. After the meal, there will be various award presentations to members. Those active or interested in ATV are invited to attend. Contact *Scott Millick K9SM, 907 Big Four Ave., Hillsboro IL 62049. Tel. (217) 532-3837, or E-mail to smillick@cnmnet.com.* Reservations are required in order to attend.

NEWTONVILLE, MA An Amateur Radio and Electronics Auction will be held by the Waltham ARA and 1200 RC at Newton Masonic Hall, 460 Newtonville Ave. For more info contact *Eliot Mayer W1MJ, (508) 664-0773, W1MJ@AMSAT.ORG.* The Auction Web Page is *http://ourworld.compuserve.com/homepages/emayer/auction.htm.*

SPECIAL EVENT STATIONS

NOV 9-10

LAKE HIAWATHA, NJ The Irvington-Roseland Amateur Club will operate the club station, K2GQ Nov. 9th and 10th 1400Z-2100Z, in celebration of the club's 51st Anniversary, "IRAC the Next 50 Years." Operation will be in the General portions of 80, 40, 20, and 15; the Novice portion of 10 meters, and 146.52.

NOV 30-DEC 1

PLYMOUTH, MA The Whitman ARC will operate Station WA1NPO at historic Plimoth Plantation, in commemoration of Thanksgiving. Freqs.: 3.970, 7.270, 14.270, 18.140, 21.370, 24.970, and 28.370; 1400Z-2100Z hrs. each day. A special QSL card will be sent to Hams and SWLs sending an SASE. Also, a 7 1/2" x 10" certificate with the Mayflower II in the background is available for the event. All replies must be sent to *Whitman ARC, P.O. Box 48, Whitman MA 02382.*

LETTERS

Continued from page 69

have no formal education and are unqualified. Their goal is to create a bigger demand for their services, which increases the need for the agencies' services, which in turn means bigger budgets, with promotions and salary increases for all.

Most local agency administrators quickly learn that they can get away with expenditures such as parties (conferences), cell phones, cars, plush offices, et cetera, because the federal and state agencies are dependent upon local expenditures to justify their bigger budgets. This is going on from Florida to California. Most northern states that have no need for migrant farm workers are not aware of this.

I know this because I worked five years for the Western Arizona Council of Governments (WACOG) in Yuma, Arizona. The description I have given is an accurate assessment of what I witnessed going on. Their local Congressman, Ed Pastor (a liberal Hispanic Democrat) is all in favor of this.

Be sure and pay lots of taxes, Wayne. The people at these agencies and on the other give-away programs appreciate it.

Well, it's easy to see why we have more people working for the government than in manufacturing. We don't want their children to go hungry so let's push Congress to increase our taxes and give everyone a raise for a job well done ... Wayne.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

Over the past few months, we have covered the what, why, and how of radioteletype; this month, let's take a look at the where.

From the beginning of amateur radioteletype, hams have clustered their activities at the low end of the ham bands, in order to facilitate contacts as well as minimize interference to other forms of communications. For "standard" Baudot radioteletype, look around the low end of 80 meters, at 3620 kHz, or on 20 meters near 14080 kHz, most times of the day. You certainly may find RTTY on other frequencies, but these are good starting places on HF.

On VHF, you will do best to check around on local repeaters, as local custom puts AFSK RTTY all over the place. In some areas, activity may be concentrated near 145 MHz, while in others it may be up near 147 MHz. Other bands' activities may be similarly influenced by local practices. Ask around.

Help on CD-ROM

While our activities may be confined to the ham bands, radioteletype itself is hardly so confined. A useful tool for searching for some of those frequencies has been put out by Jeorg Klingenfuss, in the form of the 1996 Super Frequency List, a CD-ROM which stores all kinds of broadcast information.

The revised software of this disk runs under Windows 3.x® or Windows 95®, and features concurrent word search facilities and individual tables to evaluate some 8,500 entries with the latest schedules of all international broadcasting services on shortwave. The English and German search engine can seek out radioteletype stations and sort them by frequency, identifier, country or language, or combinations of keys. **Fig. 1** is a screen shot of a search for Hebrew language stations, showing the kind of information available. There are even other lists of 1,000 abbreviations and 12,820 formerly active frequencies, all on one compact disk. The current price is DM60, and the disk is available from Klingenfuss Publications, Hagenloher Str. 14, D-72070 Tuebingen, Germany. For more current information on this, or other Klingenfuss publications, check out Jeorg's home page at: http://ourworld.compuserve.com/homepages/Klingenfuss/ and let him know that you read about him in this column.

"What exactly would I need, besides the C-64 and a 2 meter transceiver, etc., to be packet capable?"

Help wanted

David Sebastio (sebastio@tesco.it) has been studying for an Italian ham license, and may well have it by now. He has been looking for RTTY and ham applications for the Mac. This has been a long-standing problem, which has been addressed here before. I have found some material on America

Fig. 1. A screen shot of the Super Freq List in use.

Online™, but precious little elsewhere. Readers with good information are invited to send contributions to David, who I am sure would appreciate it, as well as to bring such material to my attention. Depending on size, we may be able to offer some of the material on the RTTY Loop Home Page.

Speaking of that home page, some miscellaneous notes include a word of thanks for the comments to Mike Stapp (stapp001@gold.tc.umn.edu), a regular reader of this column and visitor to the page who, along with others, has offered suggestions and comments. Watch the page for implementation of some of these items in the future. Hopefully, Antonio Hernandez Garza XE2HWH (hgarza@bestit.dgit.seit.mx) has used some of the material from the RTTY software collection to get his Kenwood TS-530S onto RTTY with his PK-232. I look forward to hearing from Mexico on this. Dale Fravel N2LWY (dlf@rfpo1.rfc.comm.harris.com) is looking for information on DS RTTY, as well as software to accomplish this mode. Again, any of you who have information for Dale, please send it to him, and let me know about it, too, OK?

Using old equipment

Michael Shovan WB2KHE, says that he has enjoyed reading "RTTY Loop" almost as long as *73* itself. While not yet equipped for the mode, he still finds the topic of interest. His only practical exposure was with the big, old, clunky monsters the wire services used to provide for radio station news departments as late as the mid-'70s (when he was last in the "biz").

Some years ago, he tried the RTTY receive program for the CoCo but couldn't get it to work, especially with a direct feed from a shortwave broadcast receiver headphone jack. (The program was keyed into an executable file from the magazine listing and stored on disk.) He had always wanted to make it work, but never got to pursue it.

Fig. 2. The CD-ROM Klingenfuss 1996 Super Frequency List.

Packet quickly put an end to all that for him at the time.

Well, Michael, as originally printed, there were a few errors in that listing, which prevented it from working as published. A correction ran a few months later. So, anyone who is still running a CoCo is cautioned to check for that correction before putting fingers to keys. As to those "old, clunky monsters," watch it—many, many hams are still using those machines. I also appreciated Michael's remarks about my other page, A.J.Recordings, the official web page for Al Jolson. You all can check that one out at: http://www2.ari.net/ajr/recs/. Notice the subtle difference in URL from the RTTY Loop Home Page.

Speaking of those old monsters, another Italian reader, Guido Sesani (bonefish@gpnet.it) sends a message detailing his problems. An old SWL, he recently rejoined the world of RTTY with an old Telereader CWR 670E (do not smile please!!) and a Yaesu FRG-100. He wrote because he absolutely does not remember how the Telereader works, and the only transmissions he gets clearly are CW. So, once again, I ask all of you if anyone has an original manual for the Telereader, a copy of which could be sent to Guido. Drop him a message if you can help him, and let me know so that I can thank you as well.

"The Klingenfuss CD-ROM can seek out radioteletype stations and sort them by frequency, identifier, country or language, or combinations of keys."

C-64 help

A reader with a piece of equipment not so old, but not so new, either, is Harry Johnson NV7K/6 (panda@northcoast.com) who writes:

"I have been reading your column in *73* for a long time, even though I am not active in any way on any of the digital modes. I do enjoy reading it anyway. I have enjoyed looking at the web sites that you mention each month, and for various reasons have included some on my hot list. I just did so with the RTTY Loop Home Page. Very interesting.

"I have a C-64 sitting in a box and have for some time had some randomly recurring thoughts about using it for packet. I have read some about 'poor man's packet,' etc., and know that there are terminal-emulating programs for the C-64 that facilitate its use for packet. As you can see, I am totally inexperienced in the digital modes. Anyway, what exactly would I need, besides the C-64 and a 2 meter transceiver, etc., to be packet capable? Where is the necessary software available?

"People usually snicker softly when I mention the C-64, and say 'Use your PC!' I use the PC for too many other things, and the C-64 is just sitting there. My expectations are not excessively high, anyway. I would just like to have the ability to communicate with some friends via packet."

Harry, there are a lot of C-64s on RTTY, and they get out just fine. Anyone who would snicker at you would probably do the same to someone driving an inexpensive car, but it will take you to your destination just as well as a luxury model. Among the solutions I have seen, the most elegant may be the old Microlog ART-1 system, being sold by G & G Electronics of Maryland for less than $50. Check with them and see if they still have any left, at (301) 258-7373, and tell them you read about it here. If they have run out by the time this is published, they may well have a handle on other solutions to your problem.

Several times in this month's column the RTTY Loop Home Page has been highlighted as the source of information, and the means of contacting me. Those of you with Web access can check it out for yourselves at: http://www2.ari.net/ajr/rtty/. There have been thousands of hits there to date. I have not said much about the RTTY Loop Software Collection lately; next month I hope to highlight a few new programs in the pot. Meanwhile, drop me a line and let me know what you are looking for, or what you have to contribute. E-mail me at: ajr@ari.net, or on America Online at: MarcWA3AJR, or on CompuServe at: 75036,2501, or scrawl me some snail mail via the post office box above. Just do it! 73

2304 MHz and above microwave transverters

Last month I discussed some of the conversion aspects of the Qualcomm synthesizer and our Microwave Group's use of this surplus material. Those of you interested in obtaining the PC board to modify it into a functioning local oscillator may contact me at the above address.

The best example I can give is shown in last month's photographs from Kiotsugi Tanumara JG1QGF. He made a very simple, neat packaging of the synthesizer that is not only attractive in layout, but also extremely straightforward in operation.

The Qualcomm synthesizer outputs frequencies in the 2160 to 2700 MHz range. Some units are restricted to a lesser frequency range determined by a more tightly constructed VCO on the PC board. These units will not go below 2400 MHz and thus are used with 10 GHz transverters requiring a 144 MHz IF and a local oscillator at 2556 MHz. This arrangement makes for a perfect fit of VCO capabilities and VCO performance.

The synthesizer frequencies I use are based on the use of a 144 MHz multimode radio as the IF (intermediate frequency), and various multiples of the output from the synthesizer as the injection frequency. For example, to operate on 2304 MHz, I use an LO (local oscillator) frequency of 2160 MHz (2160 + 144 = 2304). To operate on 3456 MHz, a local oscillator of 828 MHz is quadrupled, mixed with the IF, and output as 3456 ((4 x 828) + 144 = 3456). If I want to get on 1296, the 2304 is divided by two before mixing ((2304 / 2) + 144 = 1296). Ten gigahertz operation is available well ((2556 x 4) + 144 = 10368).

What system you use for a local oscillator, be it a crystal oscillator or a more sophisticated synthesizer, doesn't matter. What is required here is a local oscillator that is accurate; accuracy is the prime ingredient and reigns supreme. The alternative is frequency uncertainty and an unstable oscillator. It will work but it's like driving a car—you must continuously adjust your system just like the steering wheel. To a radio system this approach is impractical and is considered a bottom-dollar solution.

Now, with the local oscillator in tow and a simple practical filter to construct with again simple components, try putting together a converter for one of the frequencies you have chosen to construct. The choice of frequency is yours, but I would suggest that you select one for which you already have some of the components on hand in order to hold down the cost of

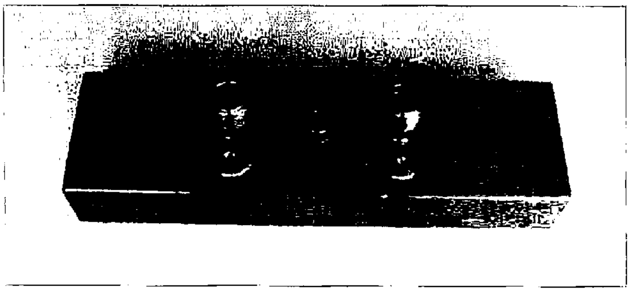

Photo A. The waveguide filter, constructed out of 10 GHz waveguide 1" x 1/2" x 3" long. The connectors used were long-tip SMAs, and the screw was a 4/40 brass screw and lock nut.

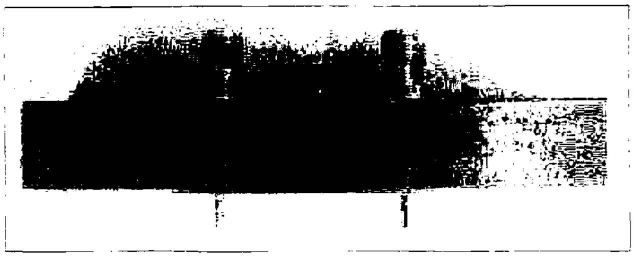

***Photo B.** Side view of the same filter shown in **Photo A.** Notice the long pins on the coaxial connector protruding and soldered on the rear wall of the waveguide. The 4/40 screw is centered in the waveguide between the two coaxial SMA connectors. In the case of lower frequency filters, the screw is replaced by a Johanson microwave variable capacitor.*

components. If you attempt a converter for which you must purchase all the components this will undoubtedly become a somewhat expensive project. Projects should be fun and interesting, and should not cause pain to the pocketbook. While we will make available all the components that we have on hand to help you construct some of these converters, make use of supplies you can find locally to hold down your costs. We are doubt and have several SMA long-stem coaxial connectors to experiment with, construct several of various lengths. I used 1/2" spacing in almost all of my filters.

This spacing from the variable Johanson capacitor was acceptable in performance, to my tastes. For a more exacting filter in terms of loss and bandwidth characteristics, try constructing a few and select the best method you have at hand. Remember: If you change the

"This might seem a little unusual—using a single amplifier for a dual purpose—but it works well in low power systems."

presenting several completed system ideas to demonstrate how we attacked the construction area on different frequencies. Almost all of the material can be obtained from us; more on that later.

More on the filter

The next item I want to cover is the filter that we introduced last month. The filter shown in **Photo A** is quite a simple one, and even when constructed with dimensional inaccuracies, it will still be capable of reasonable operation. The limits of your construction depend mainly on the components used for the capacitor and on its physical size and value. The filter response curves will be affected by the distance between the coaxial connectors, the size and value of the filter, and the size of the waveguide used. If you are in

ingredients you will change the type of cake you are baking. It should not matter to a great extent if you use different types of connectors and variable capacitors. Just keep in mind that if you stray far, you must be prepared to adjust the circuit to suit the components used. I stayed with miniature SMA coaxial connectors and RF suitable high Q RF variable Johanson capacitors in my construction.

I don't have a pile of the very small units used in the 3456 filter; try using a brass screw and experiment with the size, starting with a 4/40 (which I used at 5760 MHz). For 3456 MHz maybe a 10/32 brass screw, or even a 8/32, would be suitable. I don't know, but for us the 4/40 was just the ticket at 5760 MHz. Give it a try. Experimentation is what amateur radio is all about. **Photo B** shows the side perspective of the

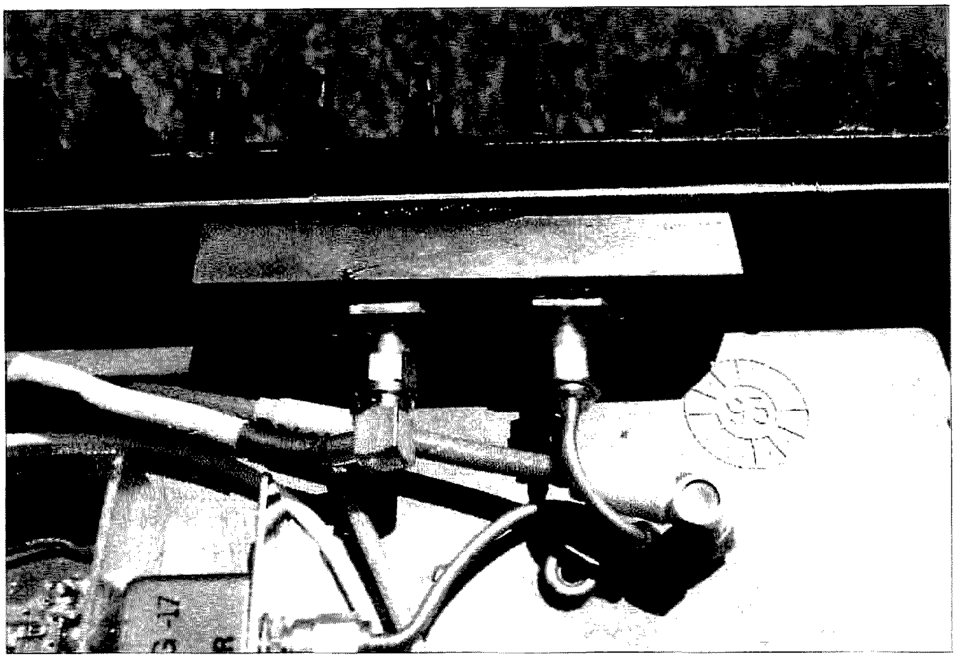

Photo C. Filter to be used at 3456 MHz.

filter constructed for 5760 MHz. You get a good view of the center pin going through the waveguide and soldered to the far end section of it.

This type of filter construction is typical, with little change other than using a variable capacitor for the lower frequencies and a brass screw for higher frequencies. The brass screw is still a capacitor in effect as it is setting a value of capacitance when the screw nears the bottom of the waveguide bottom. In this application, the value of the screw is something near 1 pF of capacitance. It might look like a screw but it is a capacitor in effect. I will probably get letters correcting me on that point but this was the easy tack to take, in describing why a screw can replace a capacitor.

Photo C is a close-up of a filter used in a 3456 MHz transverter that I constructed. The goop on top of the filter is a blue silicone RTV automotive gasket material. I used it to hold the filter in place on my cabinet side wall to prevent the filter from rattling around. Using RTV allows easy removal and replacement of material that doesn't require grounding. If at a later time an improvement is incorporated, changes can be made very easily by removing the RTV and rearranging components, as mounting holes and nuts and bolts are not required.

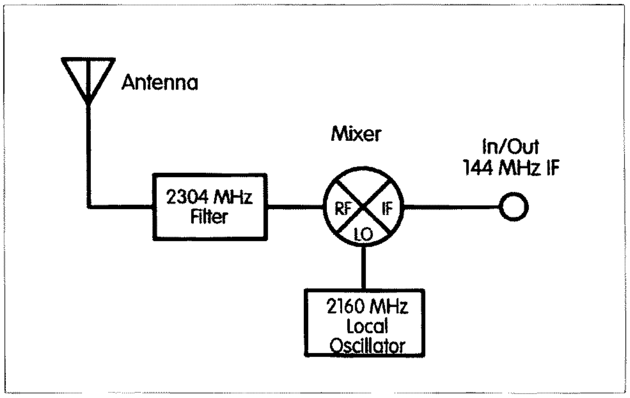

Fig. 1. Basic minimum RF transceiver using a local oscillator mixer and an RF filter. The simplicity of this arrangement allows operation without using coaxial relays. It is a "Peanut Whistle" low power rig, but works quite well.

Transceiver construction

Now for constructing the main transceiver. What does it take to construct a simple transceiver? Well, after you select an IF frequency that determines your local oscillator frequency to operate on a specific frequency, all you need is some coaxial switching and a mixer to function. Of course, this is a very basic system, the minimum needed to communicate. See **Fig. 1** for a diagram of this basic system.

A local oscillator, a mixer, an IF transceiver (2 meter in my case), coaxial relay switching, and a filter to prevent out-of-band RF radiation are all that is required. Improvements can include a receive preamplifier and a transmitter amplifier to beef up the mixer output level. When the basic system uses a mixer and just a filter, the antenna is a direct connection to the mixer, and is bidirectional. This system does not require coaxial switching due to this bidirectional connection. When any amplification is inserted in this path it directionalizes the path and requires coaxial switching.

Depending on your selection of RF amplification, there could be two different types of coaxial switching scenarios. The first and most common arrangement uses an individual receive RF preamp and a separate transmit amplifier. This most familiar, common arrangement of amplifiers requires two single-pole double-throw coaxial relays (SPDT) to accomplish RF switching. See **Fig. 2** for this RF switching configuration.

The other amplifier scenario is accomplished with a single RF amplifier serving both functions as an RF preamplifier for receive and an RF amplifier for transmit. This might seem a little unusual—using a single amplifier for a dual purpose—but it works well in low power systems. The RF switching trick to pull this arrangement off is to use an RF transfer relay. This type of relay is quite different from the SPDT used in the example described above.

"It might look like a screw but it is a capacitor in effect."

What makes a transfer relay special is that it has four connections for the RF switching path, with two connectors tied to each other at any one time. When it is operated, it reverses its path connection and makes contact to the other two connections, "transferring" the input and output connections. See **Fig. 3** for a diagram of a transfer switching configuration.

When you use a transfer coaxial configuration, the RF amplifier is tied between two fixed poles of the transfer relay. One of the other poles (coaxial connectors) that are vacant is tied onto the mixer RF port; the other is tied to the antenna. Which switching state the transfer relay is currently in depends on where you left the transfer relay

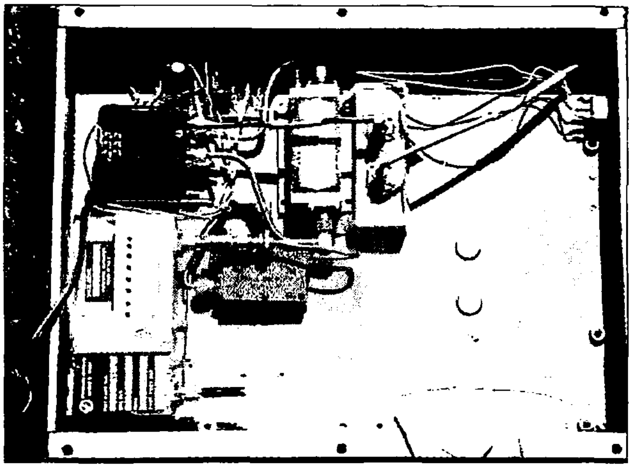

Photo D. Full view of the completed 3456 MHz transceiver/converter.

switching state. This relay is not a typical normally-open or normally-closed contact arrangement, but rather a latching relay. With a latching relay, it's a teeter-totter type of switch. It takes a DC voltage applied to a specific contact to change the switch direction. As the switch is operating it also opens the DC control voltage to the appropriate relay coil.

To transfer back to the original state (let's call it the receive state), you must apply a DC voltage to the other relay coil. Again, only a short pulse of DC is required as it also opens in this teeter-totter fashion. The point to note is that there are two relays in a transfer relay and they only use a momentary DC current to switch. This means quite a current savings from the battery operation point of view.

An SPDT coaxial relay requires current all the time that you want it to remain switched. To confuse the point, most SPDT relays are of this type but they can exist in a momentary relay function. In either case, the SPDT relay can be either momentary or continuous. From an operational point of view, the switching is the same with either relay.

Choose your relay with care, making sure it will function at the frequency you want to use. Almost all SMA type miniature relays that I have come across will handle modest power in the 10 watt range, up to and including 10 GHz, with little problem. An ohmmeter test for operation might show good results, but a loss test at the RF frequency you intended to use will show if it is usable or not.

Well, there you have some of the considerations that we have used to construct our transceivers. None of these units is a real powerhouse transceiver, but they do function and have all made contacts that were quite respectable. I hope that they show you that these rigs are not too cumbersome to construct, and that they can be repeated with other types of components that you might have on hand. That's the main thrust: Construct a rig for your frequency and put it on the air.

Sure, I could sell you something just like all the other supply houses, even though I work out of my home. However, my venture into amateur electronics is for fun and enjoyment, and, hopefully, to help you get something off the ground and on the air. I can't say it enough: Use your junk box, and always keep an eye out for new items to add to it. A well-stocked junk box will help you hold down costs on projects.

Letters and comments

Just one for the road this month: From time to time I am asked to design some big project gratis. In some cases this involves some basic idea with which someone wants help. Some have far-reaching implications, as in the case of (no names here) who wanted me to design a "worst-case engineering nightmare type of radar for aircraft collision avoidance." Well, I assigned that request to the round file for obvious reasons and liability questions. Recently, however, a friend gave me the solution to the design problem. I thought it worth repeating.

The solution to the worst-case radar aircraft avoidance system is as follows: "You should have pointed (him) towards new optical passive laser technology. A non-coherent diffuse electromagnetic wave source in the terrahertz region. This is used, together with a detector connected to a neural network, to determine the presence of objects. Triangulation from two detectors is used to estimate distance."

So simply put and with flair. I love it!

Well, that's it for this month. I will continue on the quest for converters for our microwave region, and stay with simplicity as best as I can. Best 73 Chuck WB6IGP clhough@aol.com (soon to change to Pacific Bell Internet Services).

Turn page for ***Fig. 3.***

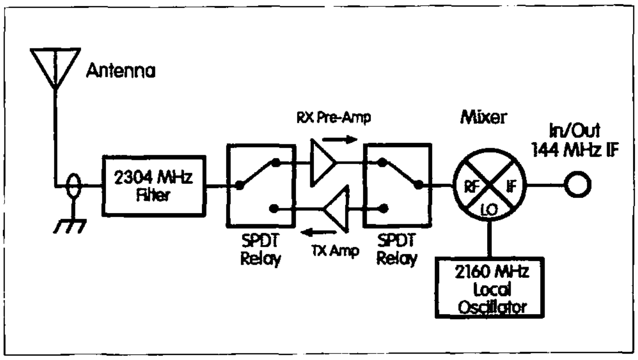

Fig. 2. RF coaxial switching using individual RF receive preamplifiers and separate RF power amplifier devices.

NEVER SAY DIE

Continued from page 55

their business incubator program, which won the prize as the best in the country for 1995. But I couldn't fight the total domination of the faculty's prestige game. I didn't want titles and battle ribbons to wear. I wanted results. Well, I got a few, but just a fraction of what I'd hoped for.

Then there was my adventure with the trustees of Central New England College, where as a consultant I tried to help them reorganize before it was too late. The faculty fought every inch of the way, and won. The result was that the college folded and everyone lost.

It was a similar story at Hawthorne College, only this time it was the students who called me as a consultant to try and save their college. Heck, I came close to buying the college just so I could make it into a model of what a college could be, with zero tuition and no government support. But the entrenched faculty prestige mindset, supported firmly by the accreditation bureaucracy, made me back off. The college folded.

Universities should make a fundamental decision. Are they going to be R&D laboratories, or teaching institutions? The two haven't mixed successfully yet. Their goals are just too far apart.

I went to college because that was what anyone who could afford it was supposed to do and I didn't know any better. I almost totally wasted four years. That was 50 years ago, when colleges weren't as bad as they are today, and I'm still grumbling. It's interesting that few successful entrepreneurs (according to an *Inc.* magazine survey) bothered to go to or finish college, thus putting themselves a few years ahead of college grads in the workplace. Well, you can get more details on my philosophy for making money in my $5 booklet on *Making Money, A Beginner's Guide*. Is Bill Gates a college grad? Steve Jobs? Just to name two billionaires that I happen to know personally. You bet they're not.

Rock

Amateur radio, in addition to providing my life with adventure, has also helped me get work—which can (and should) also be an adventure. In this case it was Graham Claytor W2MYL, one of my fellow RTTY pioneers

The Last Skeptic of Science by René. We all know there have been a bunch of ice ages, right? Wrongo, says René! And that the moon causes the tides. That volcanoes are caused by magma leaking from the earth's core. That the transmutation of elements is difficult. That the earth, with it's iron core is a big magnet. Plus a bunch of other blasphemies, which René disproves most convincingly. Heck, we all know that two materials of different weight will fall at the same speed in a vacuum. Galileo proved that once and for all. Could Galileo have been wrong? You betcha. René spins out one after another of thoroughly accepted scientific truths and slays them. Boy, will you have things to talk about after reading this baby! 179p, 81/2 x 11. Order **SK** $25 from Radio Bookshop.

NASA Mooned America by René. The proposition that the Apollo flights were all faked and NASA never got anyone to the moon is patently ridiculous. I'm still waiting to hear from anyone who has read this book and still believes the moon landings weren't the biggest hoax in history. René has done his homework thoroughly and cites 30 darned good reasons why he thinks we've all been lied to. 176p, $8^1/_2$ x 11. Order **NA** $25 from Radio Bookshop.

Cold Fusion. Look, you ignored my blandishments to get involved with repeaters, which would have led you into getting rich via cellular telephones. Then you ignored my pleas to get involved with personal computers. So you're not a Bill Gates, Paul Allen, or Steve Jobs. You can't say I didn't try. The next biggie is going to be cold fusion. You can get an Overview report on the subject for $2 (order **CFO**) from Radio Bookshop. Or you can jump in and subscribe for 12 issues. The special *73* subscriber rate is $75 instead of $98. Warning, some of the articles are technical, some are on experimental systems. Order **CF-sub** from Radio Bookshop. Motorola and Bechtel are already jumping in on this new technology, yet the leading American researcher in the field had his lab in his garage and had less than $5,000 invested. He's now working for Clean Energy Technology Inc. (CETI).

The Book List by Wayne Green. This is a list of 83 books that I say you are absolutely crazy if you don't read. And none of this "I don't have time to read" crapola. These books are the best books I've found in a whole bunch of fields. Many were recommended by readers as being top notch. It's time to become educated on health matters, our school system, our corrupt government, history, science, communicating with plants and animals, child development, the occult, and so on. Order **BL** $5 from Radio Bookshop.

AIDS Cure. Can a simple $19 electrical (for the parts) gadget you should be able to build in an hour cure the dread "incurable" AIDS virus? Plus clean out any other virus, microbe, yeast, parasite, or fungus in the blood? This approach was discovered by the Albert Einstein College of Medicine and then kept secret. The medical industry's worst nightmare is a cheap cure for expensive diseases. Are tens of thousands of people dying unnecessarily? This has the original Beck device, plus a reprint of the May *73* Miller unit. Can this even cause a weight loss for fatties? And can the magnetic pulse unit used to zap the HIV virus out of lymph glands be used to regrow male pattern baldness? Order **AIDS** $10 from Radio Bookshop.

The Junk Box Power Supply

A short course on power supplies.

Don Crowder N5TWH
Central Texas C & E
P.O. Box 349
Kingsland TX 78639

Every time you turn around these days, it seems you need a power supply. The kids have dozens of electronic toys and we adults have more than a few of our own that use lots of expensive batteries. All these gadgets seem to have jacks on them for external power, but the little wall transformer type power supplies are expensive in their own right. Luckily, most of us have junk boxes full of transformers, diodes, capacitors, and transistors. The experimenters' books and magazines are full of power supply circuits but most of them are built around one or another integrated circuit. Granted, these are excellent circuits, but "chips" have lots of legs, they cost more, take more time to assemble and test, and you never have the right chip in your junk box anyway.

Well, here's a nice, simple, discrete transistorized regulator that's usable between 3 and 24 volts and which can be assembled in a couple of hours or less. Since none of the component specifications or values are critical, you probably already have the parts. There's more here, however, than a neat, easy power supply. This is a pretty good short course on power supplies in general, and you may even learn a trick or two.

The transistors

The whole electronics industry uses NTE numbers for replacement transistors so these numbers are shown (see **Fig. 1**), but you can look up the number of the transistor you happen to have and, if it crosses to the NTE number, it's usable (that's called a back-cross). If you don't have a cross reference book, then call your local parts distributor and beg.

The zener diode

The zener value should be 2 volts larger than the desired output voltage. Zener values can be increased, in increments of .6 volts, by placing them in series with ordinary diodes (like the 1N4000 series) installed in opposite polarity. For example, where an output of 9 volts is desired, requiring an 11 volt zener, let's say that all you can find in the junk box is a 9.1 volt zener. You can add three ordinary silicon diodes to get a value of 10.9 volts, which ought to be close enough to serve. The zener's power rating is unimportant (see **Fig. 2**).

The transformer

Even serious technicians can't always figure out which of the odd transformers, in that box out in the garage, are suitable for a given voltage and current requirement, hut with some common sense and practical knowledge, you can make a fairly close "guesstimate."

First, you need an old appliance cord (in good shape) with insulated clip leads on the end opposite the plug. Before

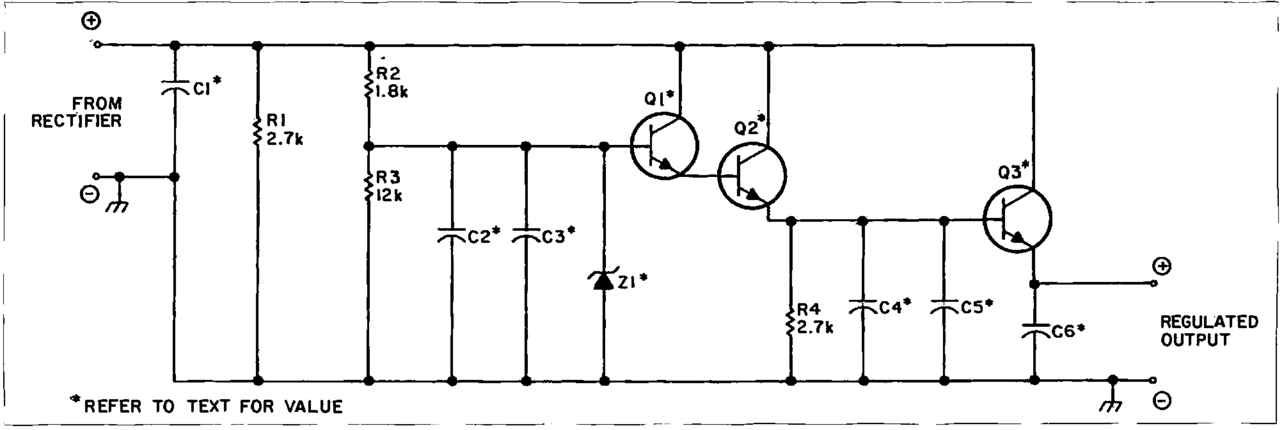

Fig. 1. Schematic diagram of the Junk Box Power Supply regulator circuitry.

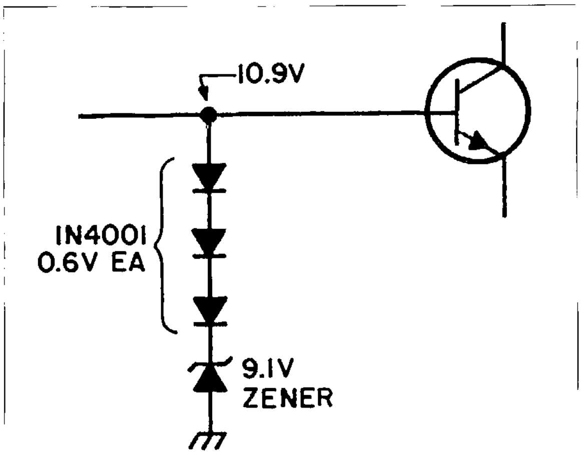

Fig. 2. The value of a zener diode can be easily increased by the addition of several ordinary rectifiers.

testing an unknown transformer, use an ohmmeter (R x 1) to determine which wires represent separate windings (by checking continuity) and note which windings exhibit resistance over 100 ohms. The windings with higher resistance can be safely treated as the primary ones. Secondary windings, in the voltage range we are seeking, normally exhibit very low DC resistance (on the order of 2 to 20 ohms). If possible, it's best to avoid transformers with multiple windings. Unused windings are not esthetically pleasing, cause confusion, and generally make a person nervous.

Testing the transformer

Before plugging it in, connect the power cord to the primary and a meter to the secondary (set for AC volts and, initially, a scale around 100 volts). Plug in the cord, adjust your meter scale, and make a note of the AC voltage, then *(safety first)* immediately unplug the cord. Your "garden variety" multimeter, analog or digital, reads RMS voltage. The filtered raw DC obtained from this transformer, assuming the use of a single diode (half-wave rectifier) or a bridge rectifier, will be 1.414 times the measured AC voltage. In the case of a full-wave rectifier, the filtered raw DC is reduced by half. For example, a 12.6 volt (AC) transformer feeding a half-wave or bridge rectifier will yield 12.6 x 1.414, or about 17.8 volts DC at the filter capacitor where a center tapped 12.6 volt AC transformer feeding full-wave rectifiers will yield 17.8 / 2, or about 8.9 volts DC at the filter capacitor (see **Fig. 3**).

"This is a pretty good short course on power supplies in general, and you may even learn a trick or two."

As a rule, the filtered raw DC should be close to twice the desired regulated output for optimum usable output current. The 17.9 volt raw DC in the preceding example would be ideal for use in a 9 VDC regulator, but usable at 6 VDC, with increased heat generated in the circuit, or equally usable at 12 VDC with reduced output current capability. To estimate the current capability of a given transformer, get a large assortment of high-power resistors, hook an amp meter to the filtered output, and clip resistors across the circuit in whatever combination causes the raw DC to load to the desired regulated output voltage. The transformer's current rating is approximately 3 amps (regulated at half the raw DC value) and this method is linear (half the size of a fist ought to be good for around 1.5 amps; twice that size for around 6 amps) but it only applies to transformers with a single secondary. I know this method sounds silly, but a crusty old super-tech once decreed "Mess not with that which works." ("Mess" was *not* the word he used.) Thus was born Dirty John's Axiom, because of which hundreds of young fellas have been better off.)

Design and Construction

The type of rectifier diodes used is unimportant as long as their voltage and current ratings are sufficient for the circuit's needs. If a bridge rectifier is used, it isn't necessary to find a fancy single unit molded bridge assembly; scrounge up four suitable diodes and build your own. A fused output lead is advisable, with the fuse's ampere rating selected to be around twice the expected output load. This circuit is good for a maximum output current of around 5 amperes. To increase the current capability to 8 amperes, connect Q2 to a good heat sink and use two identical transistors in parallel for Q3. The output pass transistor, Q3, must be installed on a heat sink and have adequate ventilation. Installation, and subsequent servicing of Q3 can be made easier by using a

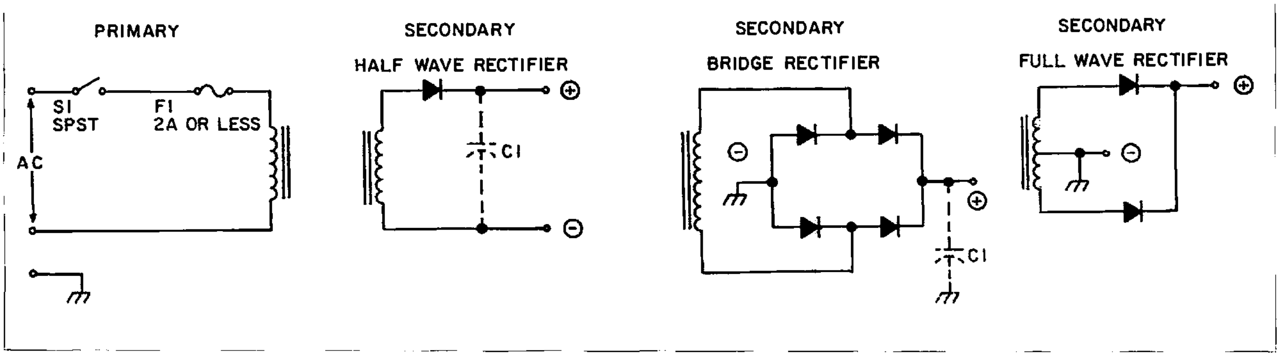

Fig. 3. The three possible configurations of rectifier circuit: Choose one based on the transformers and rectifiers you have available.

socket. If two output pass transistors are used, they can be effectively equalized by installing them three or four inches apart on the heat sink, bridging the emitters with a six-inch piece of solid #16 or #14 bare copper wire, and making the emitter connection, from Q2, to the exact center of this solid wire (this can also be done for the collectors but take care to locate the wires well clear of one another). Quick and easy access to the output can be accomplished by using the two-pin quick disconnects, found in auto parts, hardware, and big variety stores. Remember that the insulated positive lead goes on the supply; the uninsulated positive lead goes on the jumper for whatever gadget you're powering (see **Fig. 4**). This configuration prevents an uninsulated live contact from coming in contact with ground.

If you don't have a single large electrolytic suitable for the filter capacitor (C1) you can use several smaller values, since capacitors in parallel are additive, to build up the desired value. Resistor R1 is a bleeder resistor that serves to discharge the filter capacitor when the circuit is turned off and should be rated for at least a half watt, but the other resistors in the circuit can all be quarter-watt.

Parts List

Q1: 2N2222A (NTE 123)
Q2: 2N5296 (NTE 152)
Q3: 2N3055 (NTE 130)

Capacitors

C1: Electrolytic; 10,000 microfarads, or larger, rated for at least twice the raw DC voltage.
C3 and C5: Electrolytic; minimum 100 to 500 microfarads, rated for at least twice the desired regulated voltage.
C2, C4, and C6: Non–polar, ceramic, Mylar™, or polyester; .005 to .1 microfarads, rated for at least 50 volts or better.
Zener diode

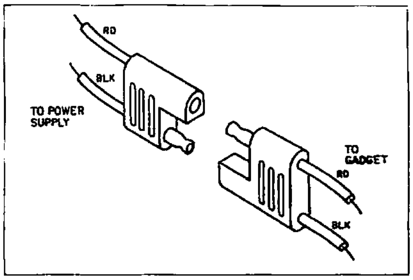

Fig. 4. The proper configuration of the two-pin quick-disconnect connector.

If current demand below 500 mA is required, simply reduce capacitor values by one third and use 2N2222As for all three transistors.

Remember, the batteries you save will feel like money in your pocket, not to mention that you'll use up some of that stuff you've been hoarding in your junk box for the last decade or two, and (here you must imagine a string orchestra playing something stirringly patriotic) on account of those unused batteries not going into a landfill, you'll be helping promote a cleaner planet as well as a better way of life for America. (Truth, justice, and the Hamerican way.)

NEVER SAY DIE

Continued from page 76

and the vice president of Pacific Gas and Electric, who got me a great job. The president of the company's wife needed a general manager for her Music Research Foundation. My background in both music and as a professional psychotherapist clinched the deal.

One of my responsibilities was to organize and run monthly meetings which were attended by some of the top psychiatrists, psychoanalysts, and psychologists in the New York City area. At these meetings these professionals discussed the research that had been done on the use of music in psychotherapy.

The end result of this was that I wrote a book which the Foundation proudly published, *Music and Your Moods*. My first book!

Now, let's leap to 1996, understanding that I have a pretty good background in both music and psychiatry, and a recent scientific report that made a lot of sense to me. You're aware that our bodies have a number of sympathetic frequencies that are used during biofeedback. Well, it turns out (surprise!) that our bodies (minds) also are sensitive to rhythms.

In experiments done on both rats and people, classical music has enhanced learning. Rats, for instance, exposed to classical music learned to figure out and remember mazes 43% better than a control group. Another group, exposed to rock music, came in at 85% below the control group. Which may help to explain the phenomenal increase in attention deficit disorder in children in the last couple generations.

If you've read Chris Bird's *Secrets of the Soil*, like I asked you to (it's on my list of books you're crazy if you don't read), you know that farmers who play music for their crops get larger, better lasting crops and have fewer problems with pests. Classical music, that is. When rock 'n' roll is played the plants are stunted and the fruits and vegetables of much poorer quality.

Well, I'm glad to see scientific, controlled tests agree with my intuition. For some reason I've always liked classical music and disliked rock. That's probably what's responsible for my attention surplus disorder. No, we never had any classical music around the house when I was young. My first exposure was

I Built It Myself!

An easy weekend project—build a variable-voltage power supply.

L. VanProoyen K8KWD
8330 Myers Lake NE
Rockford MI 49341

Although most of us have a couple of 12-volt power supplies around, they usually wind up being dedicated to permanent duty. Most of us need a power source with fairly good voltage regulation for projects we're working on, and I frequently need some odd voltage like 5 or 9 volts. So I built a supply that provides DC voltages between 3V and 16V at up to 5A, and it's small and light enough to be portable. It's turned out to be a very handy supply for general bench use.

The circuit

I used an LM317T three-terminal adjustable voltage regulator to control a power transistor that regulates the output voltage level. It's a simple circuit, but quite effective in providing a stable output voltage over a wide current range. The LM317T is capable of handling up to 1.5A by itself. By adding a power transistor, the current regulating capability of the circuit is effectively multiplied severalfold. In this case, with a 2N3055, this regulator circuit can safely handle up to 10A (the maximum rated collector current for a 2N3055 is typically 15A). The circuit is shown in **Fig.1**.

"A defunct piece of consumer electronics might be an excellent source."

The maximum current a supply like this can deliver is mainly limited by the transformer. I used one rated for 25V at 4A continuous duty because I had it lying around. Any available transformer with a secondary winding of 18 to 25 VAC at 2 or more amps will work. A defunct piece of consumer electronics (e.g., a VCR or old transistor TV) might be an excellent source. Obviously, the voltage and current capabilities of the supply will depend on the transformer you have available.

I used a 10k, 10-turn pot for voltage control because I happened to have one, but any 5k to 15k pot will work.

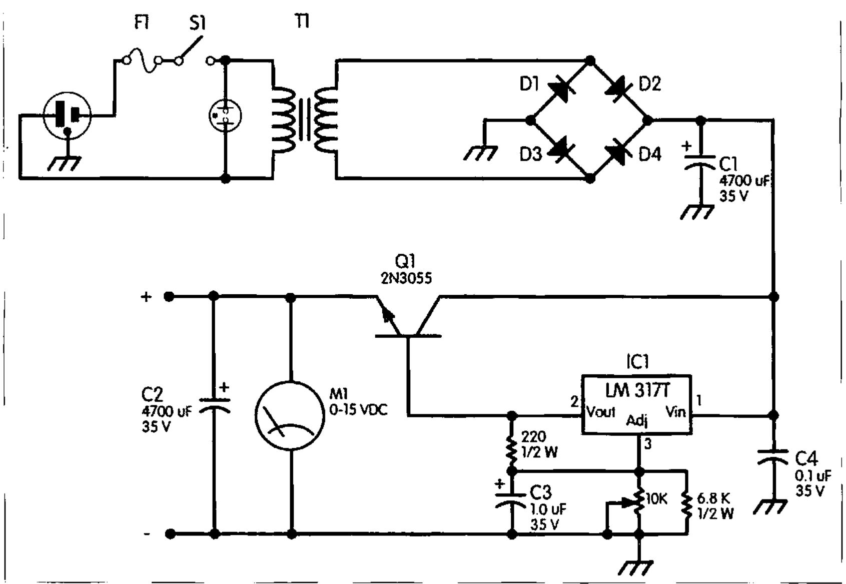

Fig. 1. The variable voltage utility power supply circuit.

Pots, together with dials similar to the one I used, turn up frequently at flea markets. I wanted to limit the variable range of my supply to be within the range of the meter I used, a 15V job, so I added a half-watt 6.8k resistor in parallel with the pot to get the desired adjustable range. You can experiment with this resistor's value to tailor the range you want. The meter is a stock item at Mouser™, but any meter can be made to work.

The remainder of the circuit is fairly conventional. I used discrete rectifier diodes in a bridge circuit, but a full-wave bridge rectifier assembly, such as the Mouser unit, could also be used, so long as you select one with adequate current and voltage ratings. The filter circuit comprises two 4,700 µF capacitors, one at the bridge and the other at the output. It provides a respectively low ripple output. If you need a supply with even lower ripple, add more capacitance.

The application notes on the LM317T advise adding a 0.1 µF bypass capacitor at V_{in}, and 1.0 µF at V_{out} (pins 1 and 2, respectively). I used 35W VDC tantalum capacitors for this; however, these are

not essential. They provide for general circuit stability and good transient response characteristics—traits I wanted for my supply. The application notes also show a nominal 240-ohm value for the resistor between pins 2 and 3 of the regulator IC, but I've found a standard 220-ohm resistor works fine.

Construction

The enclosure shown in **Photos A** and **B** is one marketed by Radio Shack™, but an adequate one can also be ordered through Mouser (#563-CU-3011A, for example).

The layout is up to you. I wanted binding posts on the front panel, but you may prefer them on the rear. Again, Mouser stocks several types of binding posts, and I've seen them at flea markets.

The regulator and power transistor should be mounted on some kind of heat sink. Also, if you use a bridge rectifier assembly, it may require heat-sinking too. I used an "L" bracket, made from a piece of scrap aluminum, visible in **Photo B**. This has proven just fine where the average current runs 2 to 3 amps. You might want to use a standard heat sink if you intend to run higher average currents for extended periods. This could be mounted on the rear panel. Heat sinks and mounting hardware kits, including mica insulators, etc., are stocked by Mouser.

I included a rear-panel fuse holder and a front-panel pilot lamp and power switch as accessories, and used a three-wire grounded AC line cord. These items are definitely "junk box" parts—use whatever you have on hand. Just make sure the lamp voltage and switch current ratings are correct for this circuit. The wiring is essentially point-to-point, using a couple of five-lug tie points to mount the small components associated with the regulator circuit. I soldered connections directly to the regulator and transistor by bending their pins into lugs with needle-nosed pliers. After completing the wiring, I used a couple of tie-wraps to neaten the job.

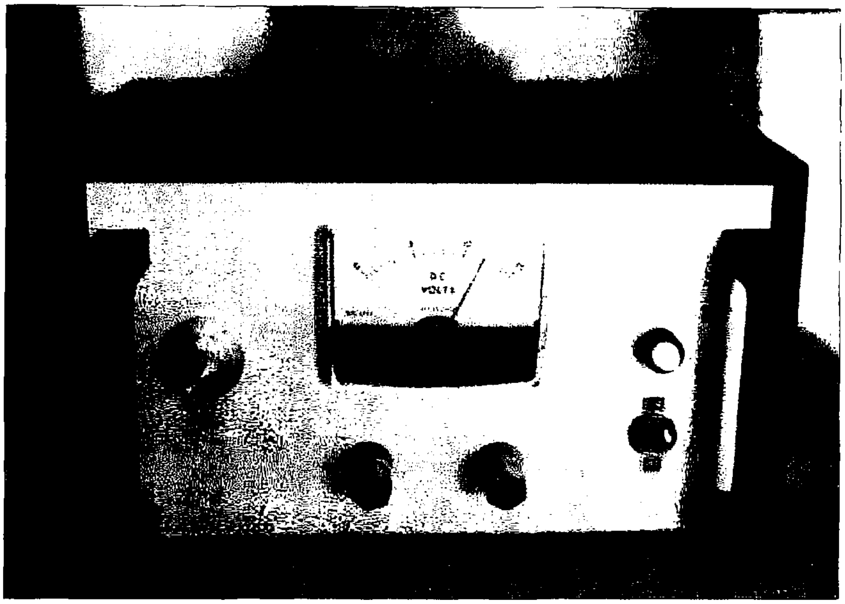

Photo A. K8KWD's variable-voltage utility power supply.

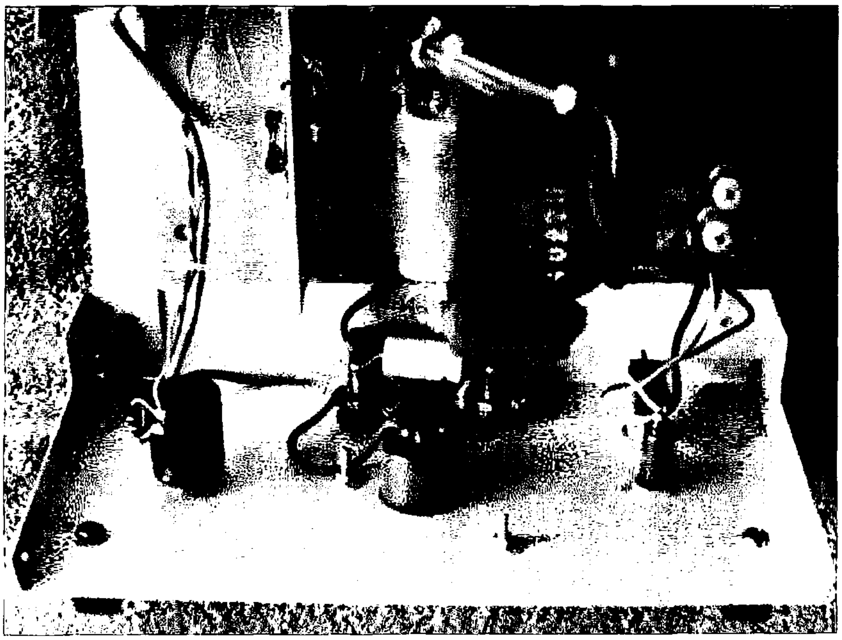

Photo B. Interior view of the power supply, showing construction details.

Operation

I've used this supply for a variety of things, such as a battery charger and a temporary power supply for a 2 meter rig. I mainly use it as a test supply when I'm building something new. It's handy because I frequently need 5, 9, or 12 volts, etc., and I simply dial it in.

Parts List

T1	Power transformer, 120 VAC pri., 24 VAC @ 4A sec. (Mouser 553-F8-24)
M1	0-15 VDC voltmeter (Mouser 39TM601, or equivalent)
Q1	2N3055 (Mouser 511-2N3055)
IC1	LM317T (Mouser 511-LM317T)
D1-4	Rectifier, 6A @ 50 PIV (Mouser 583-BR605)
C1-2	4700 µF @ 35 VDC (Mouser 539-SKR35V4700)
C3	1 µF @ 35 VDC tantalum (Mouser 539-SKR50V1.0)

Still stressed out!

Last time, we were examining the effects of the three kinds of stress that damage electronic gear: mechanical, electrical and thermal. This time, let's take a look at the components themselves and how the three stresses affect each one.

Semiconductors

Mechanical stress is rarely a factor in semiconductor failure. You can throw a transistor or an integrated circuit across the room all you want, and it'll still work. That wasn't always the case, though. Early point-contact devices and germanium parts were mechanically fragile, but that era ended around 30 years ago. Today's parts are quite hardy. You pretty much have to crush modern semiconductors to kill them.

Electrical stress is another matter! While bipolar transistors will stand plenty of abuse, overvoltage can punch holes through their junctions, shorting them out. All semiconductors exhibit this failure mode, but CMOS and FET parts are much more susceptible to it than are bipolars. Typically, "overvoltage" situations occur when inductance is involved, such as with tuned circuits leading to antennas in the output stages of radio transmitters; that's why SWR is a problem for solid-state output stages. Another common culprit is a transformer or other coil in a switching power supply. The reason inductance causes trouble is that it can transform current into voltage. The result is that voltages can be present which are actually higher than the power supply voltage used to generate the signals, and those voltages may not be entirely predictable, as in the SWR example above.

Pulling a lot of power through semiconductors doesn't directly destroy them, but the resulting heat sure can. Probably more semiconductors are blown by their own heat than by anything else. Of course, small-signal stages don't make significant heat (at least unless something goes seriously wrong), because the currents involved are quite small; so, at today's low circuit voltages, the resulting power in watts is very tiny, typically in the milliwatts. Output stages and power supply circuits, though, can make quite a bit of heat. Why do semiconductors get hot? It comes down to resistance and efficiency: all semis have some resistance (as does anything besides a superconductor), so none is completely efficient. The product of inefficiency is heat. Analog circuits, in which the active elements are often in their linear regions (somewhere between fully on and fully off), are the least efficient, because the semiconductor is acting as a variable resistor. Digital circuits, which turn on fully saturated (as far as they can go), are considerably more efficient, but even they produce their share of heat. That's why heat sinks are both important and common, and why today's big microprocessors often have those little fans on top of them.

> **"You can throw a transistor or an integrated circuit across the room all you want, and it'll still work."**

Externally generated thermal stresses are rarely a problem for semiconductors. I suppose it's possible for one transistor to generate enough heat to damage another one mounted on the same heat sink, but it certainly isn't likely. With semiconductors, most thermal problems result from internal heating.

When semiconductors fail, they can become either open or shorted. Many open parts end up that way after being momentarily internally shorted; the resulting "overcurrent" then overheats the part and opens the junctions. That's why you may find an open transistor and a blown fuse at the same time!

Resistors

Mechanical stress sometimes fractures power resistors, especially when they're hot, but resistors are generally hard to break. They can be easily snapped when bent, though, as they are rigid and brittle, much like glass or clay. So, if you sit on your HT, expect some broken resistors. (Of course, the PC board will probably be so far gone that it won't matter.)

Pulling too much power through a resistor is the easiest, and most common, way to destroy it. In tube gear, resistors actually used to catch on fire now and then, but that's pretty rare today. More likely, a resistor killed by an over-power situation will show some blackening, and it may even be cracked in half, but it won't be burned to a crisp.

It's important to remember that resistors are supposed to generate heat; that's the natural product of resisting current flow. Of course, it's not the heat we want, it's the resistance itself, because it limits current flow or reduces voltage. But, we can't escape the heat. That's why resistors are rated in watts; the heat generated is directly proportional to the power (in watts) going through the resistor.

Resistors are not active elements, so they don't cause their own demises, at least not very often. In the vast majority of cases, a failed resistor means something else has gone, too, causing a short circuit that pulls excessive power through the resistor. That's an important clue to remember when you're servicing a circuit and come across a burned or opened resistor (they virtually never fail shorted). Look for the connected semiconductor and check it out; either it or something driving it will be shorted.

Capacitors

There are so many kinds of capacitors that it's hard to classify them all as the same parts! The major kinds, including electrolytic, ceramic and plastic, have different characteristics, both in operation and failure.

> **"Caps shouldn't get hot!"**

Electrolytic capacitors, including tantalums, use a thin oxide layer to electrically separate the two sides. That layer gives them properties similar to those of semiconductors, particularly where mechanical and electrical stresses are concerned. It's pretty hard to physically damage an electrolytic cap unless you step on it, but a voltage significantly higher than the part's rating will punch holes through the oxide and short out the part. Plenty of electrolytics die from "overvoltage". But, don't manufacturers take the voltage rating into account when the circuits are designed? Of course they do, but some circuits exhibit voltage variations that exceed the caps' ratings. Also, failure of another part can subject a capacitor to voltages not anticipated by the circuit designer. For example, if a 5-volt regulator shorts out and feeds 12 volts to a circuit intended for 5 volts, some 6-volt tantalum caps may get blown in a hurry. In my experience, regular aluminum electrolytics are quite a bit more tolerant of short-term overvoltages than are tantalums; those little things short out very easily. I've seen plenty of shorted tantalums, even in circuits where the voltages never exceeded the caps' ratings. I consider tantalum caps to be among the least reliable parts in our products. Why use them? They offer lots of capacitance in a small package, are closer to their rated capacitance than aluminum caps, and are stable over time. I still don't like the things, simply because they short out so often.

Internal heating of an electrolytic capacitor indicates a problem, except in very rare circumstances. Basically, caps shouldn't get hot! When one does, it's probably getting ready to die. I've seen some

electrolytics in switching power supplies that got noticeably warm in normal operation, but even they didn't get hot. Usually, a hot cap means it's leaking, so it's acting like a resistor. If you see a hot cap, change it, unless you're sure it should be that way.

Externally generated heat can kill electrolytics, though, mostly through drying the electrolyte out of them over a period of years. I've seen some whose capacitance slowly went down until the cap couldn't do its job, because it was basically an open circuit. The heat of tubes used to do that to electrolytics all the time, and the caps were made out of paper in those days, making the problem even worse. With today's sealed aluminum parts and cool circuits, it shouldn't happen, but it still does now and then. The dried-out caps I've seen have all been near heat sinks that got very hot in normal operation, like you might find in the output stages of RF and audio power amplifiers. A smart designer will keep the caps away from the heat sinks.

Ceramic caps are among the most reliable parts in existence. They can be shattered by strong force, but, unless you bend one, you won't break it. And, unless something has exceeded their voltage ratings, you'll probably never see a bad one. I've only seen two, I think, in all the years I've been in electronics! The basic design is pretty foolproof: two plates separated by a ceramic insulator. It doesn't take much thickness for the ceramic to withstand pretty high voltages. Still, some small ceramic caps are rated at around only 50 volts, which isn't all that high. I've never seen a shorted ceramic part, and the two open ones I've run into have both had mechanical failures where the leads connected to the plates.

As with all caps, internal heating should not occur. Some ceramic caps used to be coated with a wax-like substance which would bubble if the cap got hot. Modern caps don't use the stuff. External heat could damage a ceramic cap, I suppose, but I haven't seen it happen. The things are pretty indestructible.

Well, I think we've covered enough for one column, so we'll continue this next time. Until then, 73 de KB1UM.

Houston TX 77083

New Fuji in orbit

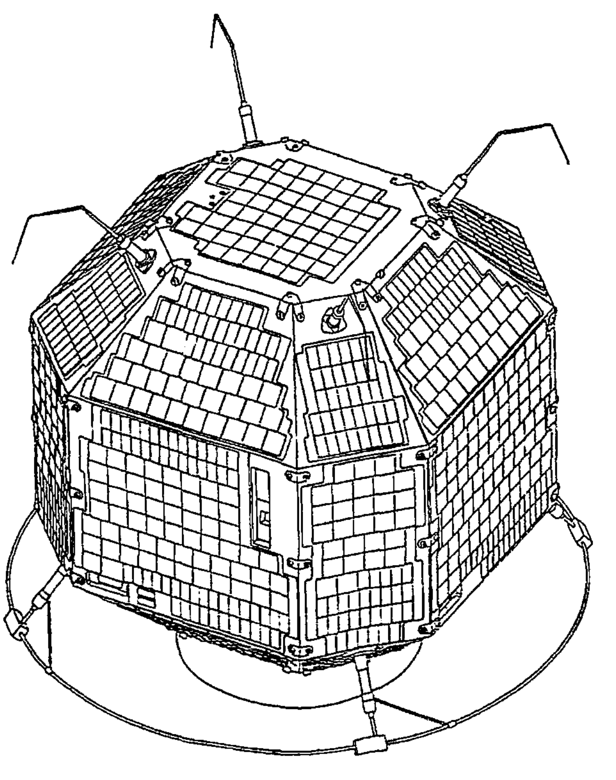
On Saturday, August 17, 1996, Fuji-OSCAR-29 was sent into orbit from the Tanegashima Space Center in southern Japan. Our newest Orbiting Satellite Carrying Amateur Radio was launched on a Japanese H-II rocket with the Advanced Earth Observing Satellite (ADEOS) by NASDA (Japan's National Development Agency). F-O-29 is performing well. It has both digital and analog Mode "J" transponders and promises to be an exciting addition to the hamsat fleet.

The rocket

NASDA has been in the space business since 1975. The latest and largest production launch vehicle is called the H-II, developed to meet the demands for large spacecraft of the 1990s. It is a two-stage vehicle capable of delivering a two-ton satellite to geostationary orbit.

The first H-II rocket was launched in early 1994 carrying the Orbital Re-entry Experiment (OREX) and other smaller payloads. Later that year the Engineering Test Satellite-VI (ETS-VI) was placed in orbit by the second H-II rocket. The third H-II test vehicle also carried multiple payloads and was launched in March 1995. One of the payloads, the Space Flyer Unit (SFU), operated as an orbital unmanned laboratory for various experiments. It was retrieved using the robot arm on the Space Shuttle Endeavour by astronaut/mission specialist Koichi Wakata.

Fuji-OSCAR-29 went to orbit on the fourth H-II vehicle. This version of the H-II included two Small Solid Boosters (SSB) on



the first stage to accommodate the payload weight and a large fairing around the satellites. The liquid-fuel rockets for both stages use liquid hydrogen and oxygen. The H-II launcher with payload stands around 150 feet, just a bit shorter than the Space Shuttle with external fuel tank.

ADEOS

The ADEOS satellite is the largest satellite Japan has ever developed, weighing approximately 3.5 tons. While the H-II rocket system can place two tons in geostationary orbit, it is also

JAS-2, FUJI-3, F-O-29

Prior to launch, the new Japanese hamsat was called JAS-2. After launch it became Fuji-3. Its two predecessors were called JAS-1A and JAS-1B before their launch, and Fuji-1 and Fuji-2 after launch. The addition of the "OSCAR" designation was made later. Project OSCAR in California built the first ham-radio satellite over 35 years ago. OSCAR-1 transmitted a simple CW beacon on 2 meters for a few weeks until re-entry. Fuji-OSCAR-29 has a complex array of computer systems and radio

"The H-II launcher with payload stands around 150 feet, just a bit shorter than the Space Shuttle."

capable of sending nearly four tons to this mission 's target orbit, 800-km high, and sun-synchronous. After full deployment, ADEOS, with its solar array, has a wingspan of nearly 100 feet. The main body, with antennas and sensors extended, is nearly 35 feet long and 22 feet thick.

The main objectives of ADEOS are to acquire global environmental data, develop and verify the operation of the Ocean Color and Temperature Scanner (OCTS) and the Advanced Visible and Near-Infrared Radiometer (AVNIR), and to demonstrate a recently developed inter-satellite data relay system. ADEOS has a design life of three years.

gear in its small frame, and should last several years. Fuji-OSCAR-20 has been in orbit for six years, and is still doing a great job, when properly illuminated.

F-O-29 has 26 sides, giving the basic octagonal shape a spherical look. It is about 20 inches wide and weighs just over 100 pounds. Most of the outside surfaces are covered with high-efficiency, gallium-arsenide solar cells. Thanks to these new solar cells on the large exterior surface area, F-O-29 has plenty of power available for the communication and command systems. Power generation is more than 22 watts at the beginning of life in orbit. F-O-20 had only 10 watts available, and F-O-12 only 6.5 watts. Enough power is available on F-O-29 to run all the experiments and computers simultaneously.

Attitude control is achieved using a sun sensor, geomagnetic sensor and magnetorquer, all under computer control. The goal is to spin the satellite at 10 rpm along the vertical axis, perpendicular to the orbital plane. This will keep the 2 meter, ring-shaped turnstile antenna continually aimed earthward. The four 70 cm whip antennas are located on the upper portion of the satellite structure.

The final polar orbit for F-O-29 has a perigee, or low point,

JA Uplink	145.900 to 146.000 MHz
JA Downlink	435.900 to 435.800 MHz
JA Beacon	435.795 MHz 100mW CW
JD Uplink	145.850, 145.870, 145.890, 145.910 Mhz AFSK (FM) 1200 bps AX.25 Manchester 9600 bps FSK on 145.870 MHz only
JD Downlink	435.910 MHz 1200 bps BPSK (SSB) AX.25 using PSK modem or 9600 bps FSK (FM) AX.25 using standard 9600 bps modem or "Digitalker " FM voice

Table 1. Band plan for Fuji-OSCAR-29

around 860 km. The apogee, or high point, is just over 1300 km. The slightly elliptical orbit can provide users with better low-earth- orbit DX opportunities during apogee times.

Communications

All uplinks are on 2 meters, with downlinks on 70 cm. This frequency combination is typically called Mode "J," in honor of the JAMSAT-built transponder that went into orbit on AMSAT-OSCAR-8 in 1978. Mode "J" has become the primary transponder configuration for many digital and analog amateur-radio satellites.

F-O-29 's digital package uses 1200 or 9600-baud AX.25 packet protocol, with four discrete 1200-baud, FSK (frequency-shift keying) uplink channels (145.85, 145.87, 145.89 and 145.91 MHz), and one PSK (phase-shift keying) channel for the downlink on 435.91 MHz. The 9600-baud FSK uplink is on 147.87 MHz. The corresponding 9600-baud FSK downlink is on 435.91

link passband (435.9 to 435.8 MHz). Most communications can be heard near the center of the downlink near 435.850 MHz. Typically, CW operation is below the center, while voice is used above center. The total transponder power output is 1 watt. A 100-mW CW beacon is associated with the analog transponder on 435.795.

An additional "Digitalker" system has been added to F-O-29. It will allow voice messages to be uploaded to the satellite for continuous repeating transmission on 435.91 MHz FM when the packet system is not active. The FM signal should be easily heard with only a hand-held scanner or HT.

More information

Additional data about the newest hamsat can be easily found on the Internet. The best source is from the Japanese Amateur Radio League. The URL (Universal Resource Locator) is: http://www.jarl.or.jp/jarl/jas-2/. Another good source of information can be found at the Southeast

"Thanks to the gallium-arsenide solar cells, F-O-29 has plenty of power available."

MHz, same as the 1200-baud PSK transmitter. The 1200-baud and 9600-baud speeds do not operate simultaneously, but are scheduled by the ground-control station.

The analog transponder is 100 kHz wide and inverting. A lower sideband signal transmitted by a ground station high in the transponder uplink passband (145.9 to 146 MHz) will be heard on upper sideband low in the down-

Michigan Area AMSAT Net web site: http://www/wwnet.com/~jsmyth/index.html. Don't forget the home page for the Radio Amateur Satellite Corporation. It's URL is: http://www.amsat.org. More information about NASDA, the Japanese version of NASA, can be found at: http://www/nasda.go.jp/. F-O-29 promises to be a lot of fun, in addition to being a valuable orbiting resource. 73

QRP

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Egad! It's November already. There may be just enough time to throw one more project together before the holidays.

Since time is rather short, I'll look at several easy-to-build kits. Many of these kits cost under fifty bucks. All of them can be assembled by beginners in a few hours. Experienced builders can be using the kits in less than half an hour.

The "easy" kits

Here is one for the rest of us. Designed by Wayne Burdick N6KR, it's about as simple as you can make a transceiver and still be able to make contacts with it. The rig is called the 49er.

In a nutshell, the 49er is a very tiny transceiver built for operation on 40 meters. Depending on the supply voltage, you can expect to see about 250 mW with a 9 volt battery, and about 500 mW at 12 volts.

Frequency control is by VXO. The fundamental crystal frequency is 7.040. Depending on how you assemble your unit, you can expect to see around 7.037 to 7.042 MHz. Your mileage will vary.

The 49er also sports full QSK operation and very low current demand on receive. Best of all, there's not a single toroid to wind!

Space restrictions do not allow me to reproduce the entire circuit description or the artwork for the PC board.

Condensed circuit description

The 49er is based around a NE602 mixer. This mixer is the entire direct conversion receiver. By using a panel-mounted capacitor with a series inductor, the crystal can be pulled up and down in frequency about 5 kHz. The NE602 is the oscillator.

To help keep down AM detection, Wayne uses a tuned circuit ahead of the NE602. A brute force RF gain control is available so you can ride herd on the incoming signal. This gain control is also used as the volume control. There is no separate volume control used in the 49er.

On the transmit side, there are only two stages, a buffer and a PA. Emitter keying is used on the buffer. The PA is biased for class C operation.

Odds and ends

I have not built a 49er. I know many, many people have. Even though this is a really simple project, at most the 49er will do half a watt. You should be a well-seasoned low power freak to tackle milliwatting on 40 meters.

The 49er does not have a sidetone. That will be up to you. The 2N3866, the final, gets very upset at the least amount of SWR on the feedline. A really good 50 ohm load will be required at all times, unless you have access to a barrel of 2N3866s to use up.

You can get a PC board for the 49er from: Jim Gates, 3241 Eastwood Rd., Sacramento CA 95821. The price is $5. Make checks out to Jim Gates, *not* to NorCal. Price includes shipping.

The DYI keyer

This is one of my favorites! The DYI keyer is a very simple digital CW keyer. It makes perfect dots and dashes. It is *not*, repeat *not*, an iambic keyer. The DYI keyer does not generate a sidetone either.

But, on the other hand, it's very, very easy to assemble. Using only two simple CMOS ICs and a handful of parts, just about anyone can put the keyer together. There's nothing different here from the basic design of the original version. However, I did add .1 inch headers for the input and output lines. Also on a .1 inch header is the speed control. This makes connecting the DYI keyer into your existing rig really easy. It also gives the finished project a commercial look. The DYI keyer is $15 postpaid. Get one by sending a check or money order to me at the above address.

From the repair bench

I have a 2 meter transceiver on all the time for packet. Even though the rig is running from the battery bank and its nominal 12.5 volts, the dial lamps burned out. Thinking "This is no biggie," I placed a call to the manufacturer for replacement lamps. Whoa! Replacement lamps for this rig are $4.65 each! To make matters even worse, there are *six* lamps.

Looking though the current Hosfelt catalog, I spied some lamps that should work. At a buck a shot, why not give them a try? As it turned out, they are a perfect fit. I'm telling you this because these lights may be just what you have been looking for. They will easily fit between the dial and subchassis of an HW-9. They would be great for lighting up the meter on your HW-8. With a bit of work, you could press some in between an LCD digital panel for backlighting. And you just can't beat the price! If you're interested, the part number is 25-290. Oh yes! Call Hosfelt at (800) 524-6464; ask for one of their catalogs.

Hot HW-9s

Right after the Dayton HamVention, I got calls about HW-9 rigs running with very hot finals. I've been down this road before, but it's worth one more trip.

If your HW-9 seems to be producing more than 4 watts of power, it's very likely generating more RF as well. Along with the fundamental frequency, there's all kinds of stuff squirting out of the transmitter. This problem seems to occur more often than not on 15 meters and 10 meters.

Perhaps the best giveaway is if one or both of the finals are running hot. So hot, in fact, that you'll leave a patch of skin on the heat sink if you touch it.

The fix is generally easy. Most of the time, one or more stages before the final are out of tune. Go back and retune the mixers and oscillators. Don't necessarily go after maximum power. Follow the directions to the letter. In eight out of 10 cases I've had on my repair bench, retuning the mixer/oscillator stages fixed the problem. You may have to replace one of the final transistors if you're unlucky.

New QRP transceiver from Ten-Tec

Yup! That's right. Ten-Tec will be selling a new 40 meter transceiver kit. Maybe by the time you read this. Right now, most of the details are still kinda gray. Specific features have not been announced, but look for full CW QSK, a Ten-Tec tradition!

If you would like to send Ten-Tec your ideas of the perfect QRP rig, or fixes to old problems with current QRP technology, send them to: Scott Robbins KY2P, c/o Ten-Tec, 1185 Dolly Parton Pkwy, Sevierville TN 37862.

The OHR-100 from Oak Hills Research

Another new rig from Oak Hills Research is underway which will replace the very popular Explorer II. The new rig, called the OHR-100, will be a single-band CW transceiver. You can pick any band you want, *except for 15 meters*. Dick has put a lot of work into this new transceiver and has made dozens of improvements. Look for a true sine wave sidetone oscillator. Also, for improved receiver performance, a double-tuned bandpass filter.

By the time this hits the newsstands, the OHR-100 should be shipping. The price is $159.95. The OHR-100 is available from: Oak Hills Research, 20879 Madison St., Big Rapids MI 49307.

Books and more books

There's an old saying that "You can't work 'em if you can't hear 'em." Most of us have no idea when to even begin listening. But there's help from Bob Brown NM7M. His book *The Little Pistol's Guide to HF Propagation* may be the ticket between static crashes and filled log books. You can pick up one of Bob's books from: World Radio Books, ETC, P.O. Box 189490, Sacramento CA 95818.

I'm getting down to the bottom of the stack of HW-8 handbooks. They are still only $11, and that includes first class postage. DX is $14 airmail. By the way, if you're in VE land, the price is the same as for US, $11. When these are gone, there will be no more printed. Get your copy from me at the address at the top of this column.

A 20-Foot Sky Hook

Build it for less than $10!

Joseph M. Plesich W8DYF
173 Brockton Road
Steubenville OH 43952

If you have a need for a neat little mast in the 20-foot category, here's one that is inexpensive and easy to construct. In fact, you can have this one up in less than an hour and have enough change from a ten-dollar bill to buy a cup of coffee.

"You can have this one up in less than an hour and have change from a ten-dollar bill to buy a cup of coffee."

This mast is not a new idea of mine, but I like it so much that I'd like to share it with you. I first read about it in Ed Noll's *Easy-Up Antennas*, published by Howard Sams, a book that should be in the library of every ham who likes to play with antennas.

To construct this mast, go to your local builders' supply store and buy two pieces of 10-foot schedule 40 PVC pipe—one 2 inches in diameter and one 1.5 inches in diameter. While I was buying the pipe, I picked up some 1/4-inch by 3-inch bolts with nuts and lock washers to connect the two pieces of pipe. I also bought two 3-inch eyebolts to put at the top of the mast.

When I got home, I laid the two pipes end-to-end on the patio. I slid the smaller pipe into the larger one about a foot. Next, I drilled two 1/4-inch holes about 9 inches apart and fastened the two pieces of pipe together with the 1/4-inch bolts, nuts, and lock washers. At the top of the mast I drilled two 1/4-inch holes in the smaller pipe and put the eyebolts in these holes. I cut two pieces of 3/32-inch black Dacron™ rope about 40 feet long and put them through the eyebolts. These ropes can be used to haul up an antenna, or be used as guys. The mast is now complete.

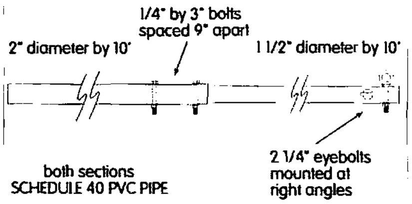


Fig. 1. Construction details for the 20-foot sky hook.

Next, I pounded a fence post into the ground and lifted the mast onto it. The mast is surprisingly light and easy to handle—except in a strong wind. However, I made the mistake of buying a lightweight fence post. When I slipped the mast over it and started to pull my antenna up with the rope, the fence post bent. I rummaged through the garage, found a piece of TV mast, drove it into the ground, and slipped the mast over it. The bending problem was cured. Next time, I'll spend the extra buck and get a heavy-duty steel post.

Now that you have found out how simple and inexpensive this mast is to construct, here are some suggestions on how you can use it:

- You can use it to hold up the center of an inverted-V antenna. Use the same type of mast, only with one section of pipe, to hold up the ends of the antenna.

- Construct a vertical for 10, 12, 15, or 20 meters by running a wire up the length of the mast. Feed it with coax at the bottom, and don't forget the radials.

- Plant three or four of these masts around your property and use them to hold up a triangle or loop antenna.

- Use it to support the ends of your sloper.

- It makes a great lightweight mast for Field Day and portable operation.

Currently, I'm using one to hold my 300 ohm feedline away from my house so it doesn't touch the roof or gutter. As you can see, there are many uses for this simple mast. I'm sure you will be able to think of others to fit your particular needs and location. Build one or two and see for yourself. 73

Payson AZ 85541

Special for November

November is expected to be a very quiet month compared to October. You may expect some geophysical disturbances around the 1st and 2nd, and again around the 22nd and 23rd. The remainder of the month will see conditions between Fair and Good. The best days are likely to occur between the 6th and 15th, when the ionosphere is expected to be quiet. With luck, we may see elevated solar flux values (75-80 or so) during this period. Do not expect miracles, however, as we're still in the sunspot doldrums, and probably will remain there at least for another three or four months. I'm hoping to be able to forecast a vigorous Spring '97 HF propagation season.

10-12 meters

Generally Poor, except for occasional transequatorial propagation with F2 openings on the best days—most likely South and Central America.

15-17 meters

DX to Africa and Latin America on the Good days possible, with short-skip out to about 1,000 miles or so in the U.S.

20 meters

Your best band for DX openings around the world from dawn to dark, and openings to the Southern Hemisphere after dark in evening hours. You can expect excellent short-skip during the daytime to 2,500 miles or so.

30-40 meters

These bands ought to be open for DX from just before sunset to just after sunrise. Signals from the east should peak until midnight, and after midnight to other areas. Daylight short-skip of about 500 miles will be possible, and nighttime short-skip to 1,500 miles or more will be available.

80 meters

Occasional DX to various areas of the world should be possible between sunset and sunrise when QRN levels permit on Good (G) days (see calendar), and also short-skip during hours of darkness to 1,500 miles or more.

160 meters

Following the usual summertime slump, this band ought to begin to come alive again during the hours of darkness when QRN permits. Try the days marked (G) on the calendar for best results. DX toward the east until midnight, and to other areas afterwards until dawn. Short-skip to 1,500 miles will prevail when the band is quiet. W1XU.

NEVER SAY DIE

Continued from page 79

when I was about seven and my family had dinner at a friend's house where he played his classical records. It was love at first hearing for me. From then on I'd often ride my bike the 10 miles to his house just to listen to his records. The first record I ever bought (I still have it) was Strauss' Tales from the Vienna Woods and The Blue Danube.

Are you exposing your children and grandchildren to "good" music, or letting other kids suck them into rock as a way of life and probably resulting mediocrity?

Maybe I should reprint my recommended 100-CD classical library list that I published in *CD Review* for people who don't know what's "good." I'll add it to my list of things I should do when I have time.

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73* Flea Market, Barter 'n' Buy, costs you peanuts (almost)–comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad. This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old-timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the January 1997 classified ad section is November 12, 1996.

On the cover: Santa stuffs stockings with goodies from Alinco. See "New Products." Photo by Jim Paliungas, Palimor Studios.

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The entire contents ©1996 by 73 Magazine. No part of this publication may be reproduced without written permission of the publisher, which is not all that difficult to get. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromat Way Ltd. of Hancock NH.

Contract: By reading this fine print you have hereby legally bound yourself to try one new facet of amateur radio in the next 30 days. Are you on packet? If not, pick up a TNC and check it out. How about RTTY or AMTOR? You'll meet some pretty friendly hams on these modes. Even the DX will rag-chew.

NEVER SAY DIE

Wayne Green W2NSD/1

Bah, Humbug!

If you are the kind of person who tends to look on problems as challenges, our country and the world are sure full of challenges. We have some great challenges in Rwanda, Bosnia, Chechnya, Sri Lanka, India, Somalia, Haiti, Afghanistan, and so on. Here at home there's the challenge of straightening up the mess we've allowed our Congress to make of our school system, health care, drugs, poverty, and so on.

Outside of those global and national challenges, which call for you to cooperate with others interested in change in order to make a difference, which is probably asking too much, how about your personal challenges? How much thought have you given to making your own life happier and healthier? And that of your family?

How about a Christmas present of a few days in the Caribbean this winter? Or a ski vacation to Aspen? Or perhaps an extended weekend in Paris, London, Berlin, or Rome? Check out those travel agency specials. Hey, it beats the heck out of some pairs of socks. And with a little extra effort, you can get a temporary operating permit and bring along an HT so you can meet some local hams. We really *do* have a fraternity, you know.

I can guarantee that the hams on every Caribbean island will welcome you with a smile and want to show you around. Ditto the Hawaiian Islands, if they're closer.

None of this has to cost a bundle, once you know the ropes. Sherry and I are thrifty travelers (we're cheap). Hey, it's fun being thrifty, even when you don't have to. But the bottom line is that without spending a lot of money we've been to Europe, Asia, Africa, South America and the Pacific. Now what better Christmas present for your wife than a few days visiting, say, Guadeloupe? It's French, and the hams are beyond belief in friendliness.

Cost too much? Only if you believe that. Travel just doesn't have to cost a lot when you know the ropes. But my next suggestion is to give some books for Christmas. They can not only be fun to read, but help change lives. No, I'm not talking about the latest best-selling novels. Check back through my editorials for books I've reviewed or invest a big $5 in my 24-page list of recommended books (available from Radio Bookshop), and pick a few that are both fun and mind-expanding to give.

Or combine the two gifts so you and your wife will have some great books to take along to read on your next trip. I always bring at least a half dozen books on my trips. There is no better inexpensive gift than a well-chosen book.

Hey, if you run into any particularly good travel bargains, please drop me a note in case I might be able to get away for a few days too. There's still a bunch of great places my wife and I haven't visited yet.

The ARRL Election

Just as it has for the almost 60 years I've been a member, my ARRL biennial director election ballot arrived in the mail. I found myself with the choice of re-electing the current director, who I don't think I've ever met, or even worked on the air, but who looks like a nice enough old chap. Or the challenger, who was not wearing a jacket, his shirt collar was unbuttoned and tie pulled loose, which looked like good signs. But, sigh, it turned out he's been a member of the ARRL board for over 10 years. Sigh.

Hobson's choice, one insider or another. No fresh blood. No real choice.

And, oh yes, in their 300 allotted words they say they want to protect amateur radio's traditional values. I think that's the current shorthand for maintaining the code requirement so as to keep the hordes of no-coders ("they're not *really* hams") out of *our* already too crowded low bands.

I haven't been keeping in close touch with the directors like I used to. Well, I used to provide a shoulder they could cry on about the stuff going on at HQ, and I was discreet about it. When Budlong was running the League with an iron hand he seldom had a problem with any directors getting elected that he couldn't control. He used to brag about how he could fix the elections. But I'm sure nothing like that is happening today.

My vote will go for the challenger. And two years from now, if I last that long, I'll vote for the new challenger. Never Re-elect Anyone. As a director, for Congress, or for President. Let's flush our political toilets as often as we can.

Ham Growth

The FCC figures for the last year are almost interesting. Growth? Well, we *did* gain 120 Advanced licensees during the last year. Of course that doesn't count the number of Advanced who got fed up with the hobby, got involved with other more important things (like golf), or dropped dead. Ooops, had their keys silenced. Well, gee, how about the General Class? With all those swarms of Techs coming in, our General Class must be bulging as they upgrade, right? Well, not quite. The number of Generals dropped by 1,841, not including those who, etc. Oh yes, the number of Novices dropped by 7,635. But then the number of Novices reached its peak in 1993. Yes, Techs and Tech+ are up, each by about 10,000 over last year. But Techs had been growing by about 30,000 a year for the four previous years, so this represents a surprising drop. About a 72% drop in one year! Yoiks. Is that a plummet?

LETTERS

From the Ham Shack

Tony Mortimer KA8ICF. So the powerful ARRL has thrown a monkey wrench into Wayne Green's speaking at the Dayton HamVention. Gosh, such power the League has over the HamVention folks. Hmmm, I spoke to Dave Forbes KD8FO at the HamVention. He is the chairman of the Forums and Speakers committee. I told him I was disappointed and somewhat ticked off that the HamVention refused to include Wayne Green among their speakers. Dave told me that this was *your* choice and not theirs. He also said that you demanded a $1,000 speaking fee, plus all of your expenses (first class air travel, hotel, food) to be paid. Since the HamVention doesn't pay speakers, they declined. I think it is high time you level with your readers. You didn't exactly lie; you just didn't tell the whole truth and nothin' but the truth. And big bucks Wayne—"easy money"—whining that he can't make any money being an exhibitor at Dayton, so he pulls out. What about the 300 plus other exhibitors Wayne? They smarter and better business people than you. Well Wayne?

Fascinating! Never, since I gave my first talk in 1955 at Dayton, have I ever demanded a speaking fee or travel expenses. Most conferences, such as the Tesla Society and Global Sciences Congress, recognizing that well-known speakers tend to attract more attendees, do pay the travel and hotel costs for speakers. And since the HamVention forum chairmen in the past have told me that I pulled the biggest crowd of any speaker, I was surprised in 1995 when I was not asked to speak. I was less surprised when the rumor mill claimed that there was some bragging about a League official having a hand in this. So, back in February, having again not been asked to speak, I sent a letter explaining that I had a particularly important message this year. No answer. Below is a copy of my February letter to Ken Allen KB8KE, who was the listed forum chairman. By the way, "Big Bucks Wayne" is well known as "Never Spend a Dollar." I'm not cheap, I'm just thrifty, as anyone who's read my travel books will attest. So when I find that I'm losing money exhibiting at Dayton and can use the same money to send out a mailing and pull in two to three times as many subscriptions, guess where my money goes? I've found that Dayton is not a cost-effective way to sell magazines. Maybe you remember the big booth Ham Radio used to have? Look where it got them. Pffft ... Wayne

"From W2NSD/1 to: Ken Allen KB8KE, Forum Chairman. While I was disappointed to again not be invited to be on the program, I can understand the pressures you must be under from the League ... I'm their worst nightmare and you certainly can't afford to offend them. I've heard from several sources how they're gloating over being able to keep me off the program. My message this year is the most important I've had since I first spoke at Dayton in 1955. I'm calling for every ham club in the country to do their utmost to get at least one local ham elected to their state legislature. The next step is for this person to get on the educational committee and introduce a bill getting the state's schools to initiate an eight-year course in the fundamentals of electronics, communications, and computers for grades 5-12. Our country desperately needs high-tech career citizens to design, manufacture, sell, operate, and service the high-tech products which will dominate both business and home in the 21st century. This can help us get radio clubs started in every school in the country and revive the high growth we had from 1946 to 1964 (11% per year, steadily for 18 years!). Without something dramatic like this, how many years can we really hope to keep our hobby going, considering the mounting commercial pressures for spectrum and the billions they are willing to pay for it? Ham legislators have an added benefit to us of being able to provide some clout when matters of interference and antenna restrictions come up. We need to infiltrate the state legislatures, so I'm really disappointed that I won't be able to get this message across at the HamVention this year ... Wayne."

Jason Spitzer KD6HYB. There are a few (three or four, I suppose) of us out here who would like to use our Macs for ham radio related things. For example, I'm really interested in getting into the digital modes like packet, but it seems the entire hobby—more so than the computer field as a whole—is dominated by DOS/Windoze software and equipment. I really don't want to have to buy another computer (even a used junker) just to get into this area. I've used both platforms extensively, and, frankly, I like my Macintosh. Anyway, can you at some point run an article catering to the Mac ham minority out here? Possibly cover sources of hardware/software, etc.? I might also add that, due to their ease of use, the Mac is really an ideal computer for newcomers to the ham radio/computer topic. It really seems like there should be more demand.

Finally, in case you haven't noticed, the world below 30 MHz has become pretty much unusable for most of us city dwellers without the $$ to go out and buy a lot of expensive DSP equipment. The static caused by cheap lamps, dimmer switches, computer hash, and the like have made an incredible spectral mess. Heck, I can't even tolerate listening to the local WJJD 1160 AM 50 kW blowtorch at night, due to the anthropogenic noise! And shortwave broadcast listening is out of the question. It's really out of hand, Wayne; I've had a Tech-plus license for over three years now, and I've studied all the way through to advanced. But why should I bother to upgrade when I can't copy anything through the noise? Even when I eliminate all RF noise sources from my house, the neighbors are still using their

junk. I don't know what to do about the problem. Certainly, manufacturers could spend a few extra cents and design some noise limiting features into their electronic products. But, no doubt, these folks had their lobbyists in Washington when the FCC and legislators were establishing standards.

Your best bet is to live on a farm in New Hampshire where there are no neighbors and then throw out all your touch-lamps. That's what I've done ... Wayne.

Kent Hufford KQ4KK. In your August editorial in the section "Is CW Dead?" you state that knowing the code helped Scott O'Grady get out of Serb-held Bosnia. That's incorrect. Scott O'Grady did not send any Morse code (CW) any time during his ordeal in Bosnia. Scott never memorized the Morse alphabet. He did send a beacon and voice mode while there.

How do I know? In June 1995 I was assigned as the Chief of Staff Army's representative to the Chairman of the Joint Staff investigations of the shootdown and the successful recovery of Basher 52 (Capt. O'Grady). I spent a week in the AOR, was on the Teddy Roosevelt, the USS Kearsarge, in Naples, Stuttgart, etc., on the investigation team. We studied the intelligence data and interviews with four-star rank on down. On our return to the US we interviewed Scott at Andrews Air Force Base. I had heard the story of his sending CW, but when I asked him about it, he replied, "What's CW?" I explained it was Morse code. He said he had not sent any Morse code and that while the older survival radios had a code sheet, the new ones did not. Scott was a very lucky guy, but the code did not help him. CW is OK, it just shouldn't be mandatory. Nor supported by a myth.

Thanks, Kent, for putting our CW-mongers straight on this. Though my ability to copy code saved my life and my submarine during WWII, I agree with you that the code should be learned and used for fun and no longer be mandatory ... Wayne.

George Lydecker KD6NEW. At last, an intelligent article about repeater coordination. Glen Zook's article expressed the frustration that many of us feel with repeater coordination as it now exists.

I'm one of those hams who live in Los Angeles under the disparity between open and closed repeaters on the 70 cm band. A quick check of any repeater guide for the 440 band shows that well over 90% of the repeaters listed are private or closed. SCRRBA, the Southern California Repeater and Remote Base Association, felt the need to coordinate yet one more private "members only" repeater to a store owner using it to help sell ham gear. This guy is also a member of the SCRRBA Coordinating Committee. SCRRBA allocated the same frequency pair to this store owner as was being used by one of the last open 70 cm community repeaters. This repeater has been coordinated and in use for all since 1993, and has provided public service for both the ham community and the public. Listen to the Metropolitan Amateur Repeater System Monday night net and you will hear friends and families using ham radio in the way it was intended. Each net begins with an open invitation to all licensed hams. This net gave me my first exposure to talking to other hams. I was made to feel welcome and I was treated as a peer. The new repeater owner, claiming eminent domain granted by SCRRBA, began a campaign to chase the open repeater users off. The situation got so bad that this guy was jamming the channel during nets.

We have hams who are as young as eight years old who would be virtually excluded from the use of 440 by the fees charged by these "business" repeaters. I listened as one young eight-year-old made her first check-in to a net, only to be jammed. And all this is under the endorsement of the SCRRBA.

Surely you exaggerate! Not even money and politics could make such a terrible situation here in America ... Wayne.

QRX . . .

Today's Young Hams Are Our Future

On the left is Alex Zagajewski N2UAO. Alex is a charter member of the Taconic Hills High School Amateur Radio Club (THHSARC) KB2YLU, and graduated fourth in his class. He was an honors student throughout high school, played varsity soccer and was the first student to successfully complete the Foundations of Research Class at THHS. Alex's project was a study of the effects of RF radiation at 146 MHz on cultured nerve cells. Alex is a member of the Rip Van Winkle Amateur Radio Society (RVWARS), has served as Field Day chairman for two years, often served as net control for the weekly ARES Net and has participated in many public service events. Alex is currently a freshman at PACE University In New York majoring in Computer Science and Mathematics.

On the right is Kyrilian Dyer N2TZT. Kyrilian is also a charter member of the THHSARC and was the Valedictorian of the THHS class of 1996. He also played varsity soccer. He is a member of RVWARS and has participated in Field Day and other public service events. Kyrilian holds a private pilot's license and can be heard aeronautical mobile over Columbia County and surrounding areas. Kyrilian is currently a freshman at MIT in Massachusetts, majoring in Aeronautical Engineering. Both Alex and Kyrilian have been Elmering other students at THHS and at a private school near THHS.

Thanks, Wayne Gearing N2ROR, for the above.

Phase 3-D Slated for Launch in April 1997 on Ariane 502

Paris, France (AMSAT News Service) — In a published report released Thursday, September 26, by the European Space Agency (ESA), Mr. Jean-Marie Luton, Director General of ESA, and Mr. Alain Bensoussan, Chairman of CNES (the French Space Agency) announced that the launch of Ariane 502 has now been tentatively set for mid-April 1997. It was also confirmed that the Phase 3-D International Amateur Radio Satellite will be on this flight. The other payloads are to be a pair of technological measurement packages for validation of the launch vehicle's ability to place two satellites into a geostationary transfer orbit (GTO).

These announcements came during a joint ESA-CNES press conference at ESA Headquarters in Paris called to outline the respective plans of the two agencies to correct identified deficiencies in the Ariane 5 launch vehicle. The actions are in direct response to a comprehensive report submitted in July by the Ariane 501 Inquiry Board that was chartered to investigate the loss on launch of the first Ariane 5 booster in early June.

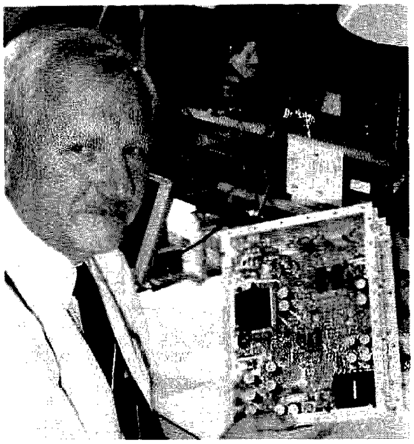
During the press conference, it was also reported that ESA's Atmospheric Reentry Demonstrator (ARD), a technology demonstration capsule for a future European manned space transport vehicle, along with an as yet unspecified commercial payload, is to be flown on a subsequent Ariane 5 vehicle, Ariane 503, which has been made a part of the Ariane-5 qualification process. This flight could take place in September 1997. The ARD had earlier been slated to fly on Ariane 502 along with the AMSAT Phase 3-D satellite.

In their announcement, Mr. Luton and Mr. Bensoussan outlined several specific actions that are now being taken by ESA and CNES to assure the correction of software contained in the Ariane 5 inertial reference system. Errors in this software were previously reported by ESA as being one of the primary causes of the Ariane 501 failure. Corrective actions include making changes to the Ariane 5 Functional Simulation Facility to make the qualification tests more representative of the flight environment as well as performing a comprehensive review of all the embedded software contained in the launch vehicle.

ESA and CNES also announced that the industrial architect on the Ariane project will henceforth assume the role of "software architect." This change will allow not only for verification of all software incorporated in equipment but also will help ensure the overall functional integrity of the launcher. Mr. Luton and Mr. Bensoussan went on to note that this means that all of the launch vehicle's software will now become subject to qualification reviews in which outside experts will take part.

In addition, the joint ESA and CNES announcement reported that working methods used in the Launcher Qualification Review have now been modified to introduce specialized audits on the most complex launcher systems in order to provide closer analysis wherever this is deemed necessary. A comprehensive review of the launcher's qualification is now also reported to be underway, along with systematic efforts to identify "degraded" modes of operation that could affect launcher elements.

AMSAT is a not-for-profit, 501(c)(3) educational and scientific organization that was first chartered in Washington, D.C., USA. Its objectives include promoting space research and communication by building, launching and controlling Amateur Radio spacecraft. Since its founding, over 25 years ago, many other like-minded organizations have been



Dr. Andras (Bandi) Gschwindt HA5WH proudly displays Phase 3-D's Battery Charge Regulator (BCR) at the Marburg P3-D Lab. The BCR is a critical piece of Phase-3-D flight hardware that will control all the spacecraft's onboard power activity such as regulating battery charging from the solar panels. The BCR was built by Bandi and his team at the Technical University of Budapest, Hungary.

formed around the world to pursue the same goals and who now also share the AMSAT name. Often acting together, these groups have used predominantly volunteer labor and donated resources to design, construct, and, with the added assistance of government and commercial space agencies, successfully launch, over two dozen Amateur Radio communications satellites into Earth orbit.

The Phase 3-D satellite, now under construction with the help of over a dozen AMSAT groups on five continents, will be the largest, most complex, and most expensive Amateur Radio satellite ever built.

Automatic Packet Reporting System (APRS)

Holy packet, Batman! We can track anything with this!

Bob Bruninga WB4APR
115 Old Farm Ct.
Glen Burnie MD 21060

APRS is a radical change to packet radio, adding a map display, a new protocol, and a simple routing scheme to communicate the positions of stations, objects, vehicles, and other graphical information in real time over standard AX.25 packet. It was designed to improve the value of ham radio in emergency situations or public service events by taking advantage of this visual tactical display. In the past, packet radio has mostly been used for passing volumes of message traffic from point to point, but has seen little use for real-time events where information has a very short lifetime. APRS reverses this trend by rapidly communicating small packets of information to all stations simultaneously. The keys to the success of APRS are: map displays to see the locations of stations and objects; unconnected/broadcast packets to all stations at once; generic digipeater routing independent of callsigns; APRS versions for the Mac, Windows, and DOS.

Map displays

Maps at any scale, from the whole world for HF and satellite communications down to the inside of the Dayton HamVention Arena, are possible! In addition to geographical displays, APRS

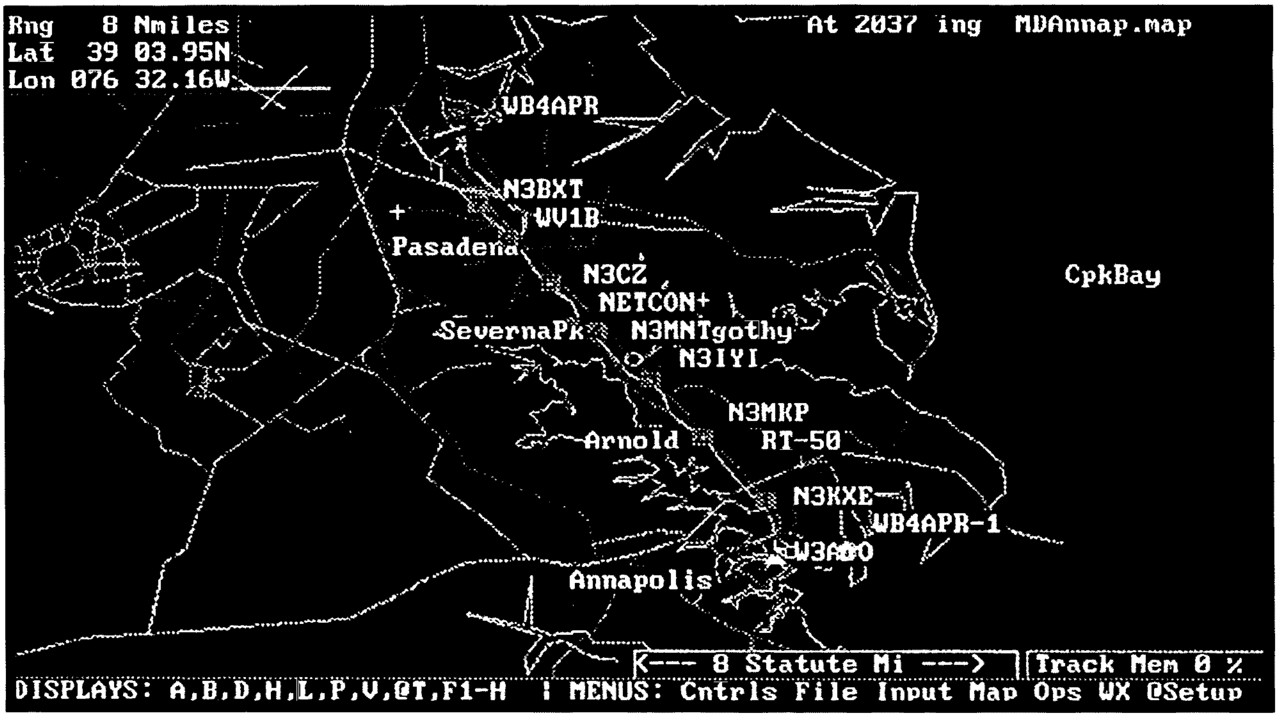

Photo A. *At this marathon in Annapolis, MD, the police officer at each checkpoint found the map display to be very valuable in predicting the arrival of the runners so that traffic could be stopped for street crossings.*

also handles and sorts operator messages, bulletins, and status packets onto separate display screens.

The utility of the APRS map displays should be obvious to anyone who has analyzed typical special event traffic. One of the greatest real-time needs at any special event or emergency is the tracking of key people. Where is the event leader? Where are the emergency vehicles? What's the weather at various points in the county? Where are the power lines down? Where is the head of the parade? Where are the VIPs? Where is the mobile ATV camera? Where is the hurricane? Where is the DX?

Unconnected broadcast packets

Another advantage of APRS over conventional packet is that it avoids the complexity and limitations of making connections to each station. APRS sends information as broadcast packets that permit any number of stations to exchange data, just like voice users would on a voice net. Any station with information to contribute simply sends it, and all stations receive and log it. To assure delivery to all stations, APRS packets are repeated periodically. After each transmission, the period to the next transmission is doubled so that older information is given lower priority than newer information.

Generic digipeater routing

An APRS operator needs no prior knowledge of the network to copy and send packets, because APRS takes advantage of the capability of any TNC at any station to serve as a relay for other stations. All APRS stations are initialized with the generic second callsign (alias) of RELAY so that any station can always get a packet out just by sending it via RELAY, or RELAY, RELAY. After monitoring an APRS channel for 10 minutes, every APRS station and digipeater will probably have appeared on his map. Using this visual geographic information, the user can then use more creative and specific routes for his intended area of interest. Similarly, all WIDE area APRS digipeaters are given the generic alias of WIDE and a second alias of RELAY. The typical path for a mobile is to use the path via RELAY, WIDE so that he is digipeated whether he is in range of a WIDE (RELAY) or any other APRS station. This usually suffices for typical radio nets.

"You can zoom in to any point on the globe!"

Applications

Although APRS was initially designed for tracking moving vehicles, it soon found applications in all facets of amateur radio. Any communications concerned with the location of anything can be tracked with APRS: SKYWARN; weather nets; hurricane tracking; both manual and automatic direction finding; plotting satellite contacts; monitoring DX packet clusters and plotting all DX spots automatically; marathon and other event tracking; plotting all stations on all frequencies for frequency coordinators; Meteor Scatter using the very short APRS packets; HF beacons (lets you see where the band is open); vehicle tracking; balloon tracking; Civil Air Patrol search and rescue; Coast Guard Auxiliary search and rescue; and frequency coordination are only a few possibilities.

Besides the map displays, there are many other display pages that collect information from packets on the channel. These displays give instant access to all the data in the network as follows:

•Latest Status: This display maintains a list of the latest status packet from each station. In effect, this is a multi-station online broadcast message

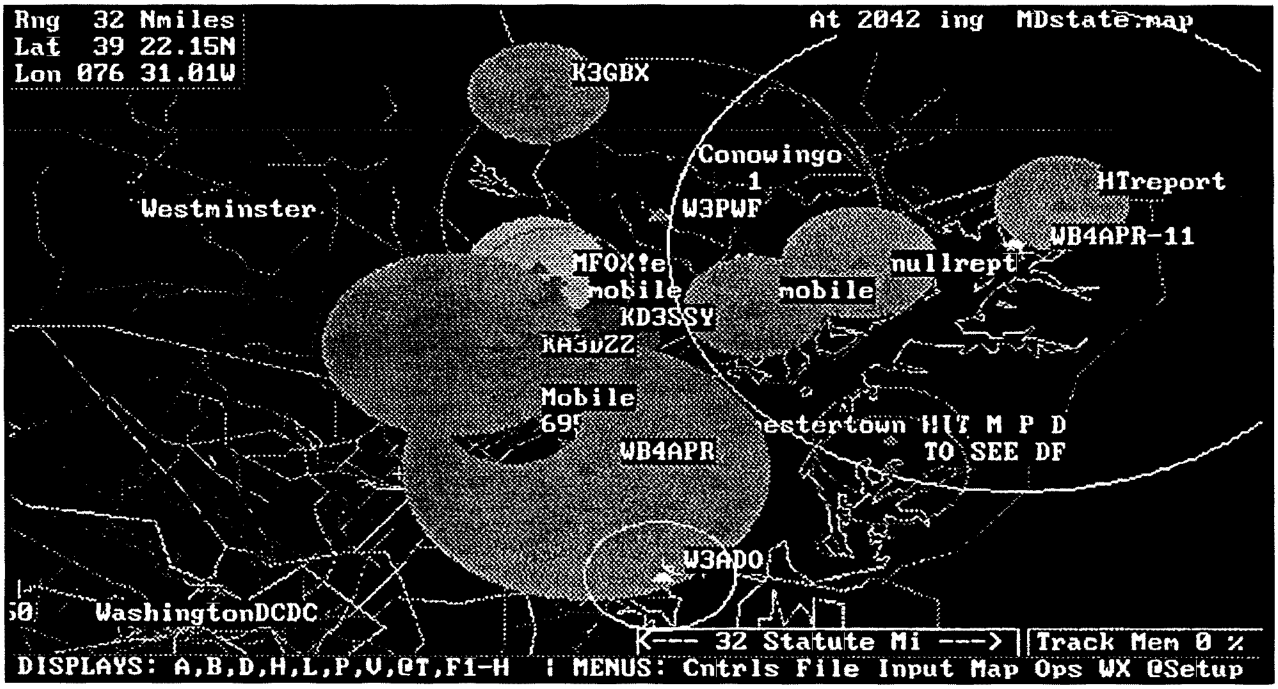

Photo B. APRS permits Direction Finding using only signal strength. Even null reports are very valuable in showing all the locations where the fox is not. *Brighter colored circles show increasing signal strength and gray circles show the null reports. The fox will be near the intersection of the brightest colored circles.*

NEVER SAY DIE

Continued from page 4

Now, pundits, how do you explain all that, and what do you see (if any) as ramifications?

And there you have it. Advanced grew at an average of 1.9% per year, which does look like growth until you figure out that around 3% are dying per year, mostly due to poor nutrition (Americans have one of the worst diets in the world) or smoking. Generals grew at less than 1% per year. Novices at 1.3%. Ho hum.

Congress Messing Up Again

Big surprise, right? Naturally, instead of tackling the source of the TVI (etc.) problem, which is the wide-open design of TV sets' front ends and the lack of RF bypassing on telephones and hi-fi systems by the manufacturers, Coingress (not a typo) is trying to put through a new law which would enable the states to close down interfering transmitters. Well, Congress (is con-gress the opposite of pro-gress?) has steadily cut the FCC's funds so they are impotent to cope with the problem, and the FCC, fought vigorously by lobbyists, has never been able to get the manufacturers to improve their equipment, so the Commission has had to pretty much just ignore the cries of distressed consumers.

Yes, some of the trouble stems from overpowered CB equipment. Being illegal, their high power amplifiers don't have to meet any regulations, so they're terribly dirty. But the design of TVs and other consumer electronics equipment is such that even a legal CB transmitter is likely to raise hob with the neighbors.

And with the proliferation of transmitters as two-way communications expands exponentially, and with no hams on our state legislatures to help protect us from really stupid state laws being passed, if this doozie (S.2025) goes through we could get put off the air by our local authorities, who won't know a ham rig from a CB. If whatever you're doing interferes with that $199 TV next door, then shut it down. Or else.

Not content with having made our school system worse than most third-world nations (and by far the most expensive in the world); not content with having made our so-called health care system a ridiculously over-priced mess; not content with having spent more of your money on their "war on poverty" than it would have cost to buy all the Fortune 500 companies, plus every farm in America, with no detectable positive effect; not content with their totally lost drug war which has been primarily instrumental in the spread of cocaine and crack; now they've got us in their sights. Maybe we need another ham lobbyist in Washington with no budget to bribe our betters. Well, you can bet that the electronics equipment manufacturers lobbyists are there, and armed with whatever it takes. When money changes hands, no matter the rationalization, that Congressman is then acting as a paid agent.

Continued on page 19

Manuscripts wanted for May 1997 Construction/Gadget issue of *73*

Write about that ham radio gadget you built, and get your article published in the May 1997 Construction/Gadget issue of *73 Amateur Radio Today*! Submit it on disk with a print out, to Joyce Sawtelle, 73 Amateur Radio Today, 70 Route 202 North, Peterborough NH 03458, by the end of January.

system. In DX cluster mode, it accumulates a list of all users and their latest commands to the cluster.

•Positions: This display shows the text of the position reports. They are time-stamped and may include brief comments. These reports may also contain DF or WX information. In DX mode, this list contains the positions of all DX spots and user locations heard.

•Maps: Maps from 100 yards up to 8,000 miles can be displayed, showing the positions of all stations. Stations reporting a course and speed are dead-reckoned to their present estimated position. Databases of most National Weather Service stations and the Civil Air Patrol search and rescue grid are built in. You can zoom in to any point on the globe! Megabytes of maps are available for APRS and more are made every day. Using the US Geological Survey $32 CD-ROMs, you can make a street level APRS map in about an hour.

•Messages: This display shows the last page of operator messages to and from your station. Incoming messages are immediately brought to the operator's attention.

•Bulletins: This screen displays all bulletins captured. They allow one station to send multiple lines to all stations.

•Traffic: This screen shows the last page of messages exchanged between other stations on the net. It is useful for "reading the mail." DX packet cluster talk traffic also shows up here.

•Heard log: This display maintains a count of the total number of transmissions from each station per hour. These statistics are ideal for displaying the connectivity of the network over varying paths, such as HF, or to see when stations enter and leave the net. On HF, this display can show propagation conditions to all areas at all times.

•Digipeater list: This display shows the raw packet header so that APRS users can see what digipeater paths are being used by other stations. The proper use of digipeaters is important in an APRS network. An asterisk in the first column means that you hear the other station direct without a digipeater! Change your UNPROTO path to NONE to chat with those stations. In DX mode, this list accumulates a list of all DX packet cluster messages heard.

•Telemetry page: This page displays the last 16 telemetry packets received. The APRS telemetry format allows for five analog channels and eight digital status bits. A complete APRS telemetry transmitter the size of a matchbox (with 1-watt xmtr!) is available for under $200.

APRS mobile vehicle location system for voice nets

APRS is almost universal, so many applications are moving off the purely digital channels and into voice networks. Since a position or object report is only a single one-second burst, many nets permit the packets on their voice channels to inform all stations of their locations. The Navy MARS program has used APRS for years on their HF afloat net. Although the military ships never report their position, the periodic position reports from the shore stations are like an automatic HF chirp sounder. The ships just leave APRS monitoring the voice phone patch channel, and they can see

"GPS trackers have been installed in a football helmet, a model of the Olympic torch, and even on cows! With the advent of GPS, everything can be tracked!"

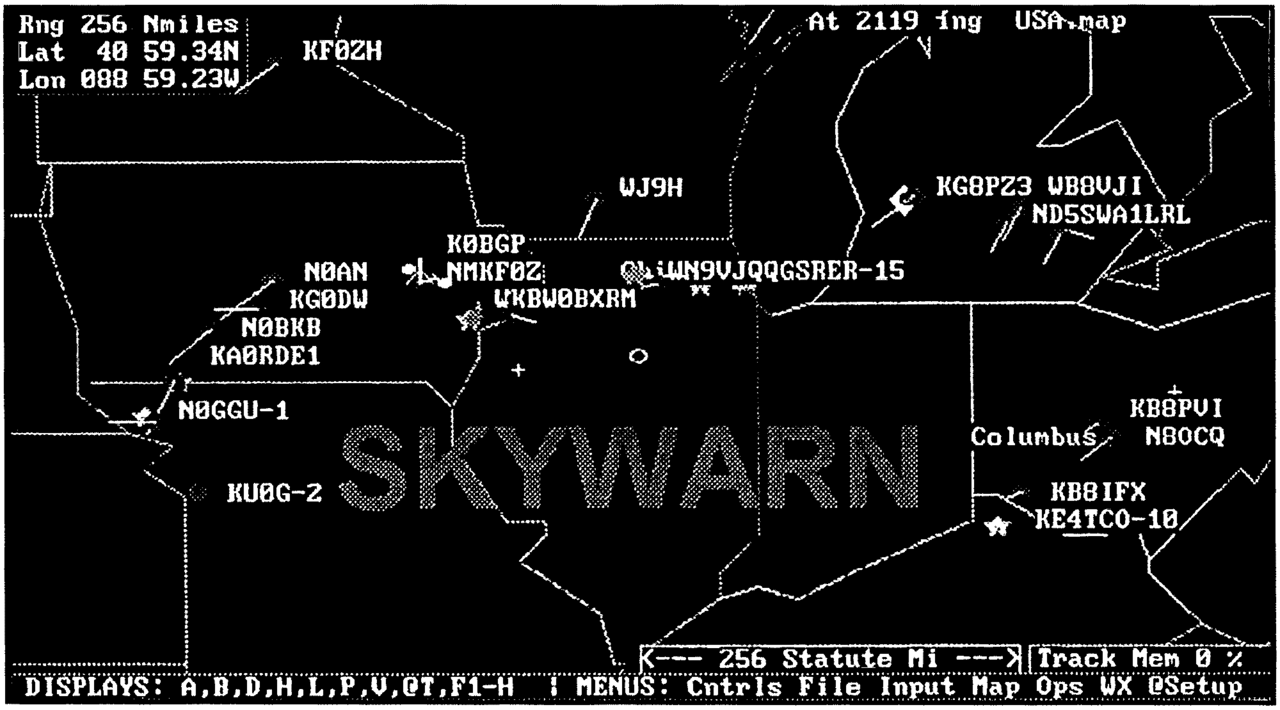

Photo C. Not only does APRS show the location of all SKYWARN weather spotters, it can also show dozens of special WX symbols and even dead-reckon the movement of the storms being tracked.

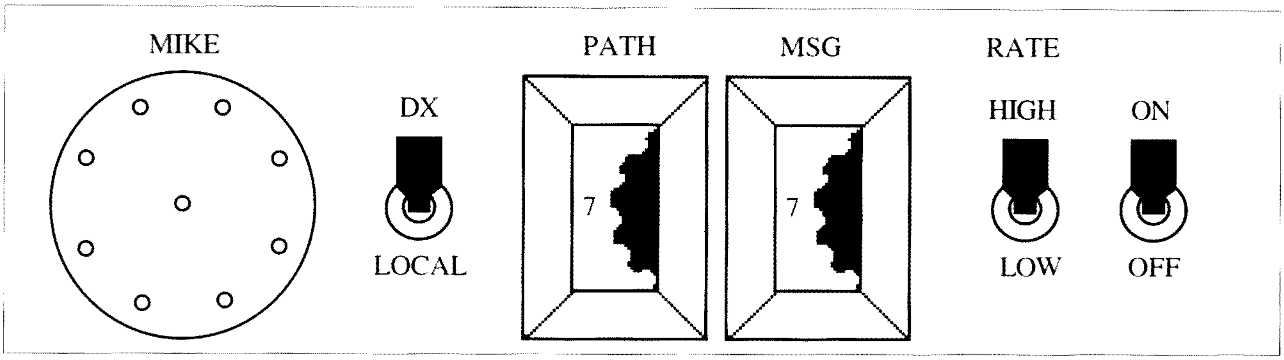

Fig. 1. The PATH thumbwheel switch gives 4 bits of routing information, and the second thumbwheel switch allows the operator to select one of seven predefined messages on the front panel of the APRS mike encoder. The rate switch allows the operator to select the high rate for frequent reporting and a four-times-lower rate for benign operations. The mike encoder is available from the Tucson Amateur Packet Radio (TAPR) Organization: @tapr.org.

on their maps at a glance what shore stations are monitoring and where the band is open, without having to make tedious voice call-ups. Not only do active stations show on the map, but the HEARD screen shows how many packets, per station, per hour, have been received.

APRS mike encoder

Recognizing the move towards automatic position reporting for all mobiles, the APRS mike encoder was designed to provide mobile position reporting without the requirement for a TNC, and additional radio and antenna. The APRS mike encoder appends a very short 0.3-second position tone burst on the end of your voice transmission, allowing automatic vehicle tracking in any vehicle with a two-way radio! The mike encoder is just a black box on your dashboard that plugs into the mike jack of any radio. A GPS and your mike plug into it, as shown in **Fig. 1**. It has a number of front panel switches to select any one of seven status messages, and to select various paths for your position report to take.

This mixing of voice and packet can be made totally transparent to the users on a properly configured repeater. Since the packet is only 0.3 seconds long, a TNC at the repeater site detects the packet on the repeater input and instantly mutes the repeater output so none of the voice users hear it. This 0.3 seconds is minimal compared to the typical one-second courtesy beep found on most modern repeaters. So where does the position report go? The TNC digipeats it not onto the repeater voice channel, but onto the local wide area digital APRS tracking channel. Since all position reports on all frequencies are digipeated onto this single APRS digital channel, stations monitoring the APRS frequency will be able to keep track of *all* mobiles on *all* frequencies!

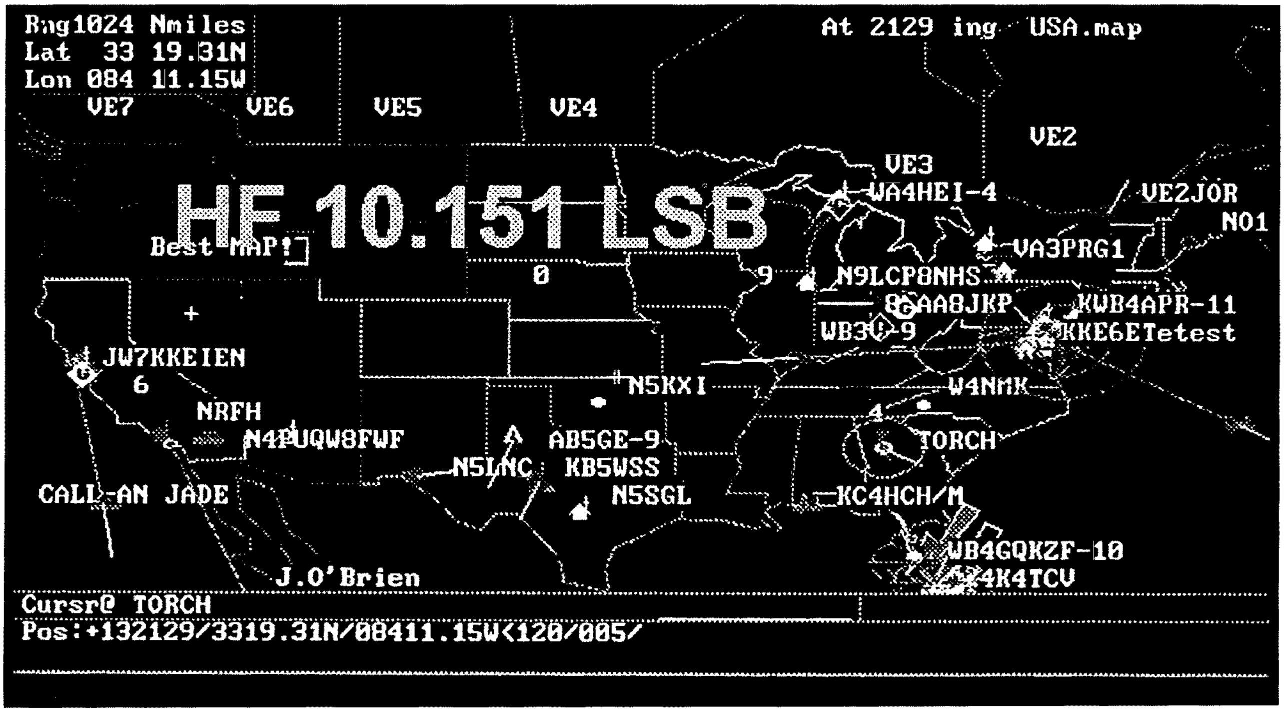

Photo D. This display shows the typical activity on the National APRS tracking frequency of 10.151 LSB. If you look closely you can see mobiles, including the Olympic Torch, among the numerous station and WX reports.

Routing path

```
x x x x }—The four routing bits.

| | or four directions if directional: NORTH = 11
| | EAST = 01
| | SOUTH = 10
| | WEST = 00
| |
| *——A 1 here indicates LONG DISTANCE vs LOCAL
|
*———A 1 here indicates an OMNI vs a DIRECTIONAL PATH
```

Fig. 2. *APRS mike encoder routing bits. A special APRS TNC at the repeater site decodes this information and sends the packet in the appropriate direction.*

Since the object of the APRS mike encoder is to encode the position into the shortest possible packet, the long list of digipeater callsigns are eliminated. In their place are only 4 bits which allow for local and longer distance reporting, omni or directional, and provision to control the direction of propagation (see **Fig. 2**). The TNC at the voice repeater is a special APRS TNC that recognizes these bits as routing information and regenerates the packet by re-inserting the appropriate digipeater callsigns as needed to represent the indicated path. To do this the TNC has five special directional UNPROTO paths pre-loaded with the appropriate north, south, east, west, and omni paths. If the omni bit is set, then the TNC will digipeat the position reports via the single callsign WIDE-N, where N is the lower 3 bits of the original SSID. This path will radiate outward in all directions with no duplicates since each properly configured WIDE digipeater will repeat it only once and decrement the -N by one. This specialized routing algorithm is called the WIDE-N algorithm and requires that the digipeater maintain a copy of the last minute's worth of packets so that it can compare and avoid duplicating a packet that it has already sent. Until the new special APRS Voice Repeater TNC is installed at all repeaters, the APRS mike encoder can operate with the full digipeater UNPROTO path in its transmitted

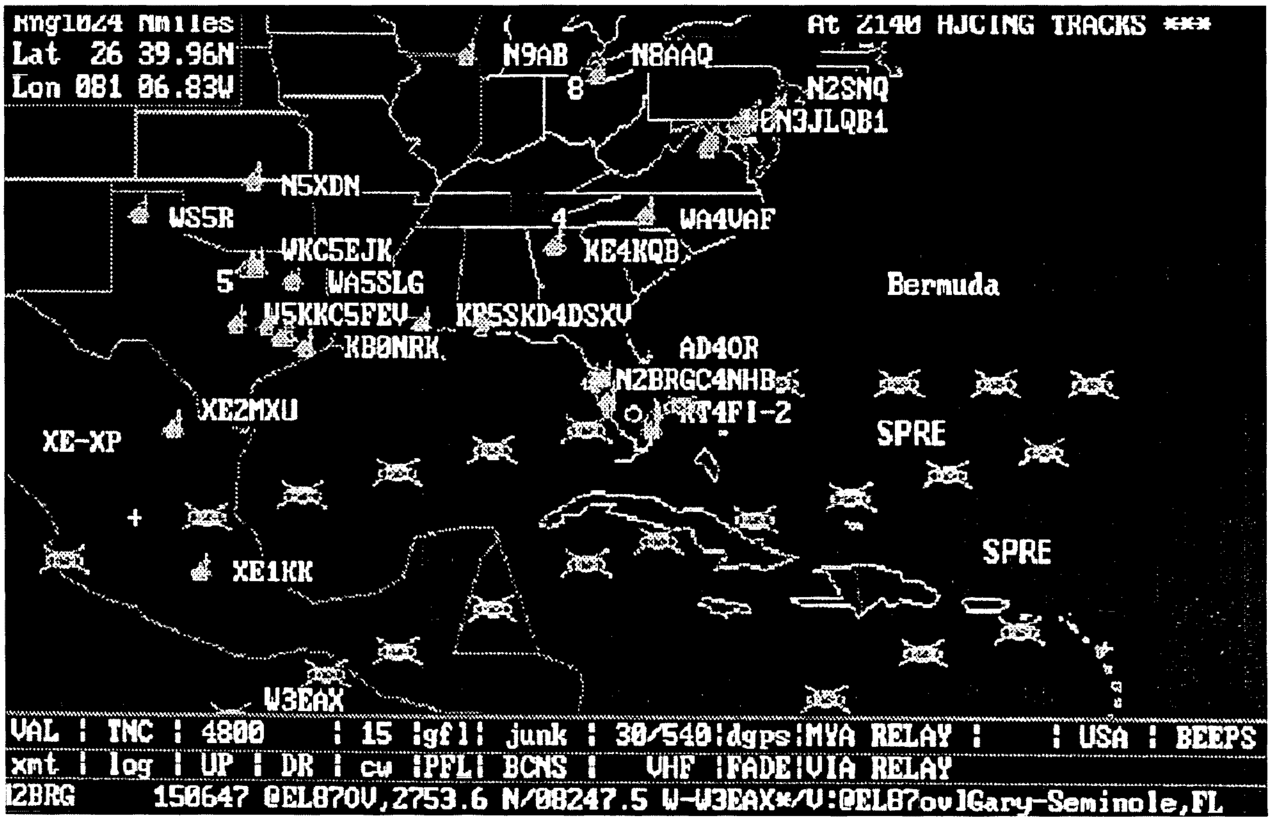

Photo E. *This APRS display was saved during the Space Shuttle SPRE mission in January 1996. In this experiment, the payload built by students at the University of Maryland beaconed its own GPS position.*

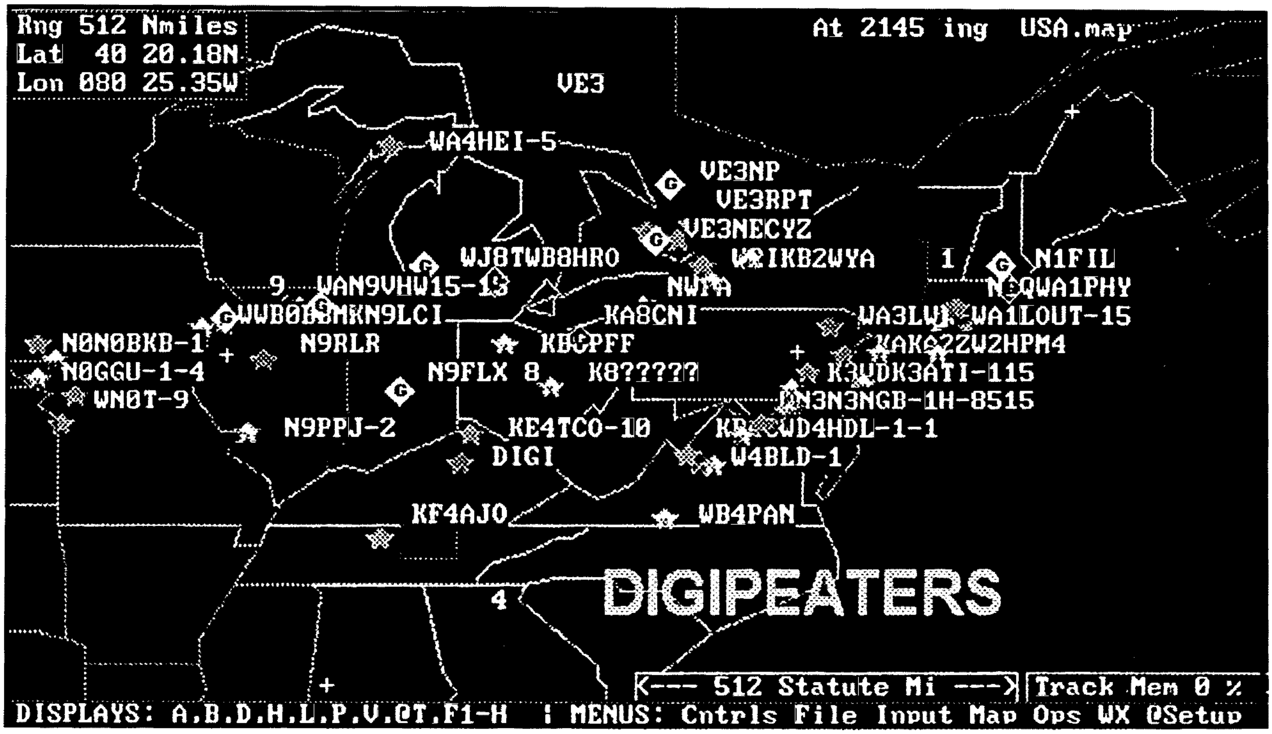

Photo F. *This display shows all of the APRS WIDE area digipeaters in the northeast. There are comparable numbers in the west and southeast.*

packets. The only shortcoming is that these packets are longer, up to 0.6 second long.

Station tracking

Although APRS automatically tracks mobile packet stations interfaced to GPS or LORAN navigation, it also tracks perfectly well with manual reports or grid squares. Additionally, any station can place an object on its map, including itself, and within seconds that object appears on all other station displays. In the example of a parade, as each checkpoint with packet comes on line, its position is instantly displayed to all in the net. Whenever a station moves, he just updates his position on his map and that movement is transmitted to all other stations. To track other event assets, only one packet operator needs to monitor voice traffic to hear where things are. As he maintains the positions and movements of all assets on his screen, all other screens running APRS software display the same maps. There is also a tracking command on the P display that will cause APRS to keep the map display always centered on a selected object.

Automatic event tracking

For predictable events such as marathons and other races (even the running of the Olympic Torch), there is a version of APRS called APRSdr that can automatically dead-reckon any number of objects along a given map course. Just place the symbols on the course, give them a speed, and APRSdr will move them along the course and transmit their new positions every N seconds to everyone on the net. For marathons, just give the leader a speed of 9 knots and Tail-end Charley a speed of 3 knots and you don't even need GPS! If the symbols get ahead or behind, simply select them with the cursor and move them to where they are. Using APRSdr in this manner frees up your limited number of GPS trackers for those assets that are not predictable, such as race officials and service vehicles.

"APRS users can set weather alarms and be alerted when conditions exceed given values."

Using APRS position reports on all packet stations

APRS can be used to monitor any packet frequency to collect information on other stations on that channel. As more and more networks include the position of all key assets in their ID packets, APRS can be used as a general purpose network topology display on any packet frequency! Even if the positions are manually entered onto an APRS map, such APRS backup files make an excellent mechanism for distributing frequency usage information in an easily maintained map format. Since APRS captures only beacons, it is a great tool for monitoring the activity of a busy packet channel. Just monitor for an evening, and APRS will identify all stations on frequency and capture their beacon text and/or ID packets. This is a great way to locate all packet stations on a frequency.

Space applications

The problem with space packet is the saturation on the uplink by hundreds of stations which makes the use

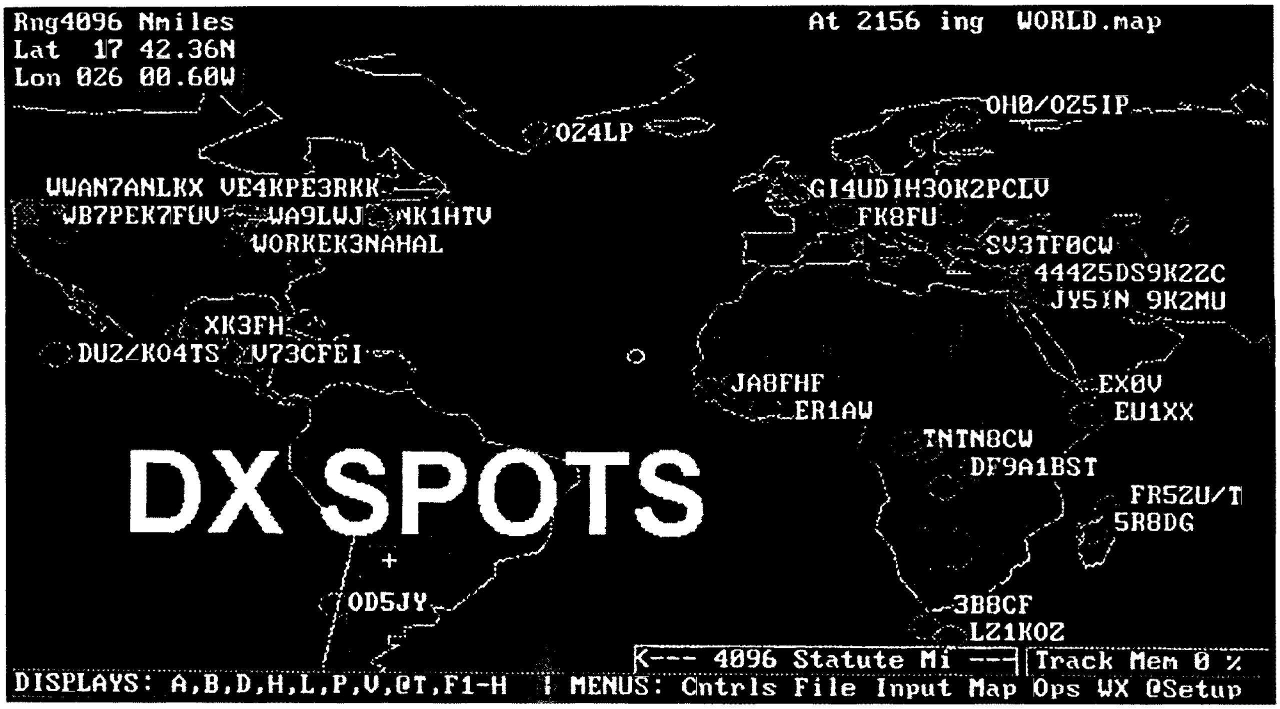

Photo G. APRS will plot the positions of all DX spots and grid squares that it monitors on the local DX cluster. It also gathers a list of all users and all messages posted on the cluster just by monitoring the frequency.

of a normal "connected" protocol impractical. The shortest possible "connected" contact requires a total of five successive and successful packets. APRS reduces this to one packet, and also capitalizes on the most fascinating aspect of the amateur radio hobby—the map display of the location of those stations.

A special version of APRS called "APRtrak" was donated to the AMSAT software library. It will compress your position report to only six letters using the Maidenhead grid square and transmit that in the TO address field of a very short packet. Similarly, it will plot any such stations heard. If everyone used APRtrak instead of trying to connect with orbiting packet digipeaters such as SAREX, then everyone within the satellite footprint would see the location of every successful uplink. In January 1995, during mission STS-72, students at the University of Maryland built a 2 meter digipeater called SPRE that flew for 18 hours from the Space Shuttle. During those brief 18 hours (with only three low passes over the southeastern USA between midnight and 3:00 AM) more than 70 stations were plotted.

Currently APRS position reporting via satellite experiments are being conducted on the amateur WEBERSAT WO-18 which has a 2 meter uplink and 437 MHz downlink. Although the downlink requires special PSK modems, the uplink can use a standard FM radio and modified TNC.

Fox hunting or direction finding

APRS will plot the location of a hidden transmitter, balloon, or interfering signal, and display the intersection of bearing lines from a number of reporting stations, and overlapping signal strength contours, if only signal strengths are reported. Finally, APRS includes the Fade-Circle Search and Rescue technique which can be used by a mobile with only an omni antenna to locate a hidden transmitter.

To use APRS for DFing, each station having a bearing report or a signal strength on the target simply enters that bearing, using the OPS-DF command. His station will then not only report his location, but also a line of bearing or signal strength contour. All stations running APRS will see any reported DF bearing lines and overlapping signal strength contours on their maps. Even with signal strengths alone (which anyone with *any* radio can report), the location of the signal can be

isolated down to a few miles or neighborhood. Further, APRS can track any DF vehicles using GPS or LORAN devices. There is an optional Doppler DF registration for direct connection to any of the Doppler DF units for automatically plotting and transmitting instantaneous DF bearings.

Weather station reporting

APRS position reports can include wind speed and direction, as well as other important weather conditions. APRS supports an optional serial interface to the ULTIMETER-II, Davis and WeatherMax home weather stations. With this interface, your station includes weather conditions in your position report for display at all other stations in the network. All weather stations show up as a bright blue circle, with a line indicating wind speed and direction. The NEXT command in APRS will successively highlight each

> ***"This is a benefit to everyone on the channel."***

weather station in turn, so that all reports can be collected at a glance. Optionally, the temperature, barometer, and wind speed can be shown next to each weather station instead of their callsigns. APRS also has a database of the locations of most National Weather Service (NOAA) sites for instant display, and can crunch a file of NOAA hourly WX conditions, and update all NOAA stations on the map. Finally, APRS users can set weather alarms and be alerted when conditions exceed given values.

DX packet clusters

The positional display and real-time user communications make APRS an ideal tool for the DX cluster user. Not only does he get to see all DX spots on the map at the instant they are transmitted to even the first cluster user, but by operating in the "monitor only" mode, he has reduced the overall packet load on the DX cluster. This is a benefit to everyone on the channel. Also, the APRS monitoring station will see the spot as soon as the first station gets it.

Frequency coordination

More and more BBSs, digipeaters, and nodes are including APRS position information in their routine beacons. If the frequency coordinating body makes available APRS backup files (or HST files) showing the positions of all coordinated services, both packet and voice, then these files can be distributed on BBSs and by other means to all hams in the area. By loading these files, users can instantly see the established frequency users in a geographical setting. Add the ability of APRS to plot crude range ring contours based on antenna height and gain to this visual reference, and you can see that APRS is useful for displaying the topology of any network, and the interference ranges of voice repeaters.

To date, APRS has been used at numerous marathons, walkathons, and special events. It has been installed on ships, boats, airplanes, and balloons. GPS trackers have been installed in a football helmet, a model of the Olympic torch, and even on cows! With the advent of GPS, everything can be tracked! This year, over 50 APRS mobiles showed up at Dayton and could be tracked all over the state.

APRSdos, MacAPRS and WinAPRS are available as shareware on most ham radio bulletin board systems. There is also an APRS special interest group on the Internet. Send a message to listproc@tapr.org and include the words "subscribe aprssig" in the body of the message. You may download these APRS programs via FTP from tapr.org in the tapr/SIG/aprssig/files directory.

Registration of these programs is $29 for APRS. $50 for Mac and $60 for WinAPRS.

APRSdos Registrations: Bob Bruninga WB4APR, 115 Old Farm CT, Glen Burnie MD 21060.

MacAPRS Registrations: Keith Sproul WU2Z, 698 Magnolia Road, N. Brunswick NJ 08902.

WinAPRS Registrations: Mark Sproul KB2ICI, 698 Magnolia Road, N. Brunswick NJ 08902.

NEVER SAY DIE

Continued from page 13

Maybe you've read about the Congressmen who call industry associations and threaten hearings unless they get money for their re-election campaigns? Oh yes, I forgot, you're too busy to read books. Besides, what can one person do, right?

Search For Intelligent Life Fails!

The $1.5 trillion (this year) search for intelligent life in Washington has totally failed. No problem, more money has been budgeted for next year. The IRS has assured us that we taxpayers will be in compliance to cover this continuing search. As Congressmen have explained about the deficit, "Heck, any business has to carry some debt. And after all, it's only a paper debt anyway. The continued foreign support of our debt means they have confidence in America. Well, we want them to have even more confidence."

Opinions

There's a big difference between expressing opinions vs. being opinionated. I enjoy hearing from readers who have opinions which are backed by solid homework. One of the problems with the Internet is the abundance of opinionated blather. Not that we don't have much of the same on some 75m nets. And that reminds me, I heard Herb KV4FZ pounding through on 20m the other morning. What does it take to get the FCC to delicense someone?

Dennis Lee

Several readers have asked me what I think of Dennis Lee and his cheap power inventions. I haven't gone to any of his demonstration/sales sessions, but I have seen his video and read his book. The book is not going to make my list of books you're crazy if you don't read. It's more a candidate for books you're crazy if you bother to read.

Here's a guy, a showman, obviously, who claims he has a great invention. It'll generate power and heat your home, making you free of the power company. It'll run your car. And so on. His book tells nothing at all about the technology. It's mainly a history of his persecution by the government and the courts, and the time he had to spend in prison. Now, I'm not used to the notion that our courts and government are right about much, but this time maybe they weren't out as far in left field as usual.

Having watched most of the big-time magicians both in person and on TV, I'm used to the idea that a good magician can make almost anything seem to happen. So the more I watched Lee's video, the more I felt I was watching a magic act, not a scientific demonstration.

I was surprised when I read that Yul Brown (Brown's Gas) would be appearing with Dennis at Philadelphia. I've watched a video of a Brown's Gas demonstration, but I didn't understand the theory of what was

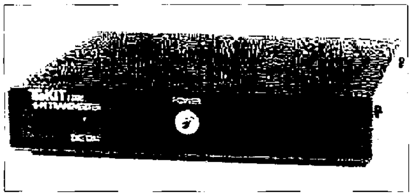
The Ten-Tec 1209 2-to-6 Transverter

An easy way to have some fun!



David McWhinnie VA3XDM (ex VY1DM)
281 Castor St.
Russell, Ontario
Canada K4R 1B8

If you are looking for a way to jump into the fun on 6m, the modestly priced Ten-Tec 1209 2-to-6m Transverter may be just the answer. Available either as a kit or pre-built, this transverter provides an easy route to the entire 6m (50-54 MHz) amateur band, using just a 2m transceiver. Providing access to a whole new set of FM repeaters, the unit is also a great way for Technician Class operators to get in on the fun of working DX openings, especially when used with a 2m all-mode transceiver. Add the pride that comes from using something you put together yourself, and this kit really has it all!

Construction is not difficult, requiring only basic hand and soldering tools, with an ordinary multimeter and some kind of power output meter being the only test equipment needed. I found that a simple HF SWR/power meter worked just fine.

At just under $100 US for the kit ($159 pre-built), you can have hours of operating fun for a modest sum, as well as the pride of using something you had a part in building.

Technical

Technically, the Ten-Tec 1209 is straightforward, comprised of a 94 MHz local oscillator and diode mixer to convert 2m signals to 6m (and vice versa), amplification and filter circuits, and PIN diodes for T/R switching. The T/R circuit is RF sensing, so the radio's antenna connector provides the only connection between radio and transverter.

"The unit produced close to 10 watts at the center of the band, and easily managed better than 9 watts almost to the edges of the band."

With a maximum driving power of 5 watts, this transverter produces 8 watts at 6m, making it ideal for use with most 2m handhelds. As most synthesized 2m rigs are user-programmable to handle TX/RX frequency offsets other than the standard 2m split of 600 kHz, the common 6m repeater offset of 1 MHz is easily managed. Should you have a 2m rig which cannot readily be set to 5 watts maximum output, Ten-Tec has thoughtfully included instructions on the necessary modifications to the input circuit to accommodate both higher and lower input powers.

No modifications to your radio are required. The assembly manual does strongly emphasize the importance of correctly assembling and testing this portion of the kit, which ensures proper operation of the transverter and prevents unwanted/spurious output signals.

After construction, I tested the unit using a commercial service monitor and found that it met or exceeded Ten-Tec's specifications. If anything, Tec-Tec seems to have been a bit conservative in describing the performance of their product. While Ten-Tec specifies a nominal output power of 8 watts (for the maximum 5 watts input), the unit produced close to 10 watts at the center of the band, and easily managed better than 9 watts almost to the edges of the band, only dropping off significantly at 54 MHz (the upper limit).

Input (6m) sensitivity was measured at .13V for a 20 dB S/N ratio (on FM), again slightly better than the nominal .15V specified. The assembly manual notes that this specification depends on the sensitivity of the 2m receiver used. In on-air use, the built-in preamp ensured that receive sensitivity was ample, with little or no noise noted.

Because of the inherent sensitivity of the 2m transceiver to its design frequencies, keeping unwanted 2m signals from "leaking through" and appearing in the 6m band is sometimes challenging. The 1209 meets this challenge well, with no feedthrough noted in on-air use.

The most noticeable thing on first unpacking the kit is its weight. Although it's only a little more than 7 inches (W) by 6 inches (D) by 1 inch (H), the assembled kit weighs about 2.5 lbs., largely due to the steel enclosure. If you've ever chased an aluminum box all over a table because it's too light to stay in place with the coax connected, you'll appreciate the physical stability of this little unit. As an aid to final testing and troubleshooting, the board can be temporarily installed upside down, which I found very handy. Mechanically, the cabinet, connectors and board (there's only one circuit board) fit well, and solidly. The finished product looks and feels substantial, and has none of the "second grade" feel sometimes associated with kit or home-brew equipment.

Construction

Assembly is not difficult, and would take most reasonably diligent hams between 10 and 20 hours, if my experience is any guide. The manual is well laid out, and is clearly geared for the inexperienced builder. Construction is organized into seven basic "phases," each encompassing a particular functional segment of the circuit. Each phase includes a step-by-step description of the assembly to be performed, a schematic and pictorial representations of the part of the circuit and board being constructed, and a concluding "progress test" to ensure that the steps have been completed correctly. I found this approach quite convenient, as the time required to complete and test an individual phase nicely fit the time available of an evening, once dinner was cleared, the kids bathed and read to, etc.

The manual contains many helpful hints and suggestions in addition to the extremely detailed descriptions of each individual step. Ten-Tec even provides a detailed description of each component to be installed at a given step, i.e. "Install resistor R39, 10S (brown-black-black)." While this degree of detail might be unnecessary, having both the value and the "description" may serve as a second check on the builder's selection of a given part. To further aid installation, the topside of the board is printed with component numbers and outlines, showing the correct orientation of each component.

Those who like to "roll their own" will undoubtedly be glad to discover that there is some coil winding to be done. The instructions are clear and the illustrations helpful, so the task is readily managed, even by the less experienced.

The only quibbles I had with the construction phase were a couple of missing parts, and a hook-up wire which did not stand up well. When I opened the kit a couple of 10k resistors were missing (other value resistors somehow got into the package), as was a ferrite bead required for the lead of one transistor. As they are common items, I had them on hand. However, Ten-Tec makes provision for even this eventuality in the manual, and in their warranty they promise to replace any such missing parts promptly.

My only other quibble was a piece of hook-up wire which is installed early in the assembly process. The roll supplied in my kit was pre-tinned, and somewhat brittle. With the number of times the board has to be flipped over and back during the rest of the construction, this particular wire broke off several times. Annoying, but nothing serious.

"Ten-Tec even provides a detailed description of each component to be installed at a given step."

On-air performance

Once the rig was checked out and tuned up, I hooked it up to a "quick and dirty" half-wave sloper dipole I had hung off my tower at about 15 feet, just to see if I could bring up the local 6m FM repeater. The repeater came up just fine, but no one was around to talk to, so I moved down to the sideband calling frequency (50.125) to have a listen. The first fellow I talked to, Bill K4LRX, turned out to be in Henderson, Kentucky, about 900 miles from my home QTH near Ottawa, Canada. I thought the 5 X 7 signal report was not bad for 10 watts, and a pretty poor antenna. I have since put up a home-brew three-element beam at 35 feet, and have had a fine time working stations up and down the East Coast, over to the Midwest, and when conditions permit, as far west as Oklahoma and Texas. The signal reports have been uniformly good, with many positive comments about how well this little rig does the job. Since I previously spent most of my time on packet and satellite, I'd never experienced the fun of (almost) QRP. There is a certain joy in discovering your home-brew 8W rig and three-element antenna is pulling in the same 5 and 9 signal report as your neighbor with 800 watts and six elements.

Conclusion

Obviously, I really enjoyed building this kit, and am having a ball using it on the air. Ten-Tec has done a good job with the kit itself, and I found them excellent to deal with when purchasing it. It happened that I had a couple of technical questions the salesman could not answer. Right away, I was put through to a technician, who had the answers and some helpful suggestions as well. This left a very favorable impression, and the performance of the kit has lived up to that impression. For someone looking for a reasonably low cost way to get on 6, and for an answer to some of those who dismiss "no-coders" as "appliance operators who can't build a thing," the Ten-Tec 1209 might just be the answer. It looks good, works well, and doesn't cost much. A good combination all 'round.

Shooting Straight Up

NVIS: A neglected short-range technique.

Peter L. Barker XF1/KB6ASH
La Jolla de Los Cabos AB-506
San Jose del Cabo, B.C.S. 23400
Mexico

The quest for long distance communication has totally captured a large segment of the ham population, to the point where multi-element antennas at expensive heights are the sign of a serious ham.

"Forgo the kerchunking and give NVIS a try."

Few things in ham radio are more thrilling than a contact with some isolated island or far-off country, or the convenience of our thousands of repeater systems. But there are times when all the long-range antennas or slick little handhelds may just not be what is required. We are perhaps best known outside our own community for the communications we provide from disaster areas when all else fails. That is just the situation where Near Vertical Incidence Skywave operation may be the winning ticket—providing reliable short- to medium-range communication as required in a disaster, or even just for semi-local contacts in mountainous areas where it may be impossible to get into a repeater.

So how can you get involved with this type of operation? By using an antenna radiation pattern that is terrible for long-range DX but perfect for local coverage, even from the deepest canyon or behind the highest hill; and that is via high angle antenna radiation.

The reason antenna height is always stressed in DX antenna discussions, and why the big guns mortgage their family jewels to purchase those big towers, is the Holy Grail of low angle radiation. Within reason, the lower the angle of radiation, the greater the distance to the first reflection point in the ionosphere and the further away the touchdown point of the reflected signal. Fewer hops make for better DX. The downside is an almost total lack of signal in the nearby skipped zone. If we take the NVIS approach, we use the opposite effect. We want our signal to cover a circle around our location to a few hundred miles out. We, in fact, want our signal to take off as close to vertically as possible.

Signals that enter the ionosphere at a suitable frequency and a very high angle will be reflected back to earth around the transmitting point. The high takeoff angle allows the signal to ignore nearby high hills, and to get into (or out of) deep canyons or gorges.

Rarely discussed in ham literature, NVIS is a standard mode used by emergency and military communicators worldwide. It is very easy and inexpensive to do, and certainly deserves to be better known, especially by groups who pride themselves on emergency preparedness.

Using NVIS

For a fixed installation it could hardly be simpler. Rule One: Forget your verticals since they excel at low angle radiation and squirt almost nothing straight up. Rule Two: Keep it horizontal and relatively low.

A dipole is probably the simplest way to go. Cut it using the usual formula for the frequency of operation and mount it anywhere from 8 to 25 feet above the ground. It can actually work fine even lower than 8 feet, but might be hazardous—people walk into the wire, which can be surprisingly invisible to someone who's not paying attention. If you have to mount the ends of the antenna higher than 25 feet or so, you can go against everything that you've been taught and let the feed point sag well below the ends of the dipole. Try to keep the included angle greater than 90 degrees as you want to raise your takeoff angle but not cause cancellation of the signal.

So, how do I handle this on my mobile, where my antennas are normally vertical? This is more of a challenge since the antenna must be horizontal, but for someone with a little ingenuity it's no big deal. In this case a larger vehicle has an advantage over the mini-compact since it has more horizontal real estate with which to play. On an RV or truck, by using 10- to 20-inch lengths of PVC tube as standoff insulators it is possible to mount a respectable horizontal doublet, if not a full dipole. On smaller vehicles, two inexpensive loaded whip antennas will work fairly well when used as the two halves of a dipole. They need not be perfectly horizontal to be useful, so they can be mounted in an inverted "V" configuration. For multiband use, two "CB" type stainless steel or Fiberglas™ whips fed with a tuner with a balanced output can be used. The military makes extensive use of these, using megabuck helical loaded whips and automatic tuners.

The whole process relies upon the ionosphere directly above the

transmitter being reflective at the frequency of operation. As reliability is the main reason for using the NVIS mode, it tends to be used only on the lower frequencies, i.e. below 10 MHz. The rule of thumb is to use frequencies no higher than 90% of the MUF for the prevailing propagation conditions. At the present low level of sunspot activity, this means 160, 80 and 40 meters are going to be your bands of choice. The later in the day, the lower the frequency. Currently at night 160 and 80 meters will probably be the most usable bands.

NVIS has proven to be a reliable means of short- to medium-range communication and belongs in the repertoire of all emergency groups. It is simple to implement and an area which has been little explored. A few dollars' worth of wire and coax or a couple of inexpensive loaded whips will get you on the air, so forgo the kerchunking and give NVIS a try.

NEVER SAY DIE

Continued from page 19

happening. Well, maybe it's my stupidity, right?

So here's Lee putting on his show in cities all around the country, selling distributorships in his magical power unit, and, as far as I know, with no manufacturing facility anywhere, or even a preproduction model of his unit. That smelled fishy to me. And now he had Brown with him, claiming that he could de-activate radioactive waste. Hmm.

Lee claims that with his technology, cars can be modified (same engine) to run without gasoline and have no exhaust. His unit will purify an unlimited source of fresh water anywhere at no cost. Garbage and sewage can be disintegrated with no negative effects. Free electricity can be produced from air anywhere in any quantity. He has the world's greatest heat storage device, the world's most efficient heat pump, and frictionless oil.

René (author of *The Last Skeptic of Science*), who lives in New Jersey, went to the Philly demo/sales show, taking along some film to be exposed to the radioactive samples before and after the Brown treatment. I know you're not going to believe this, but Lee called off the radioactive demo and René was locked out of the hall.

When I first began hearing about Lee I was hoping that maybe somehow he was on to something. The book and video didn't help. And when I called his office they said there was no one there who could talk technically to me, and that Lee was on a national tour selling distributorships and wouldn't be back for several months.

I figured that if what he was doing made any scientific sense this could be another new technology that I might be able to help grow into an industry with a publication. Always looking.

Lee's Better World Technology works out of a post office box in a small northern New Jersey town which is less than 30 miles away from René's home. René says the talk up there is that Lee's group is planning on leaving town.

If you've read about the Lee inventions or seen them in operation, let me know what you think. Since what he is selling seems too good to be true, maybe it is.

Cancer Update

In the last 25 years, though billions have been spent on cancer research, the survival of about 97% of cancer victims has not been improved one little bit. Well, you ask, how about chemotherapy? What doctors don't want you to know is that chemo doesn't work except for a few very rare types of cancer. Worse, it can cause many more problems, including even more deadly cancers.

You know, early in this century cancers were exceedingly rare. Today, one in three of you are going to have the trauma of dealing with cancer. The doctors will want to operate or use chemo, or probably both. When cancer strikes, you have a decision to make. A big decision. Are you going to put your trust in doctors and believe and do everything

Woodhouse Communications' APT-2CP Omnidirectional Antenna

... and its perfect sidekick, Hamtronics' LNG-137 receiver preamp.

Larry Antonuk WB9RRT
P.O. Box 452
Marlborough NH 03455

I had completed construction of my new weather satellite receiver (see Hamtronics R139 review, *73*, November 1996), and had hooked it up to my discone antenna. I stumbled through the demodulator instructions, and had actually received and viewed lots of Automatic Picture Transmission (APT) pictures. Overall I was pleased with my success. As I began to decode more and more pictures, however, I found that I was becoming more and more critical of the results. The main problem was that the overhead passes were too short. Only rarely did I get a full screen image; in most cases I was recording a two- or three-inch picture with each pass. Even these images were broken up at the beginning and end of each display, and the pictures were cluttered with black and white spots and streaks. Something was obviously amiss, and I had a pretty good idea what it was.

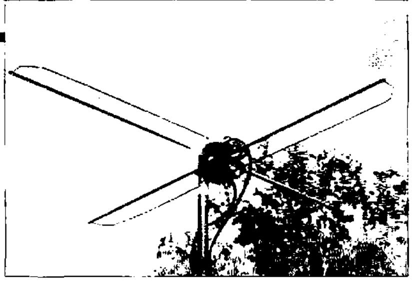
During my days as a Novice I heard an adage that has stayed with me: "A dollar put towards the antenna is worth twenty put towards the receiver." Adjusted for inflation this might come closer to two hundred dollars towards the receiver, but the message is clear. If you want good reception, you have to make sure that you capture the best signal available at your location.

Choosing an antenna system

When it came to antennas for overhead satellite reception I was somewhat in the dark. I quickly learned that there were two main paths to take. The first utilized a circular-polarized, fixed omnidirectional antenna with a fairly wide beamwidth, pointed straight up. This antenna made use of two crossed driven elements that sat above a pair of crossed reflectors, and was called a "turnstile" since it resembled, well, a turnstile. The second method also made use of a circular-polarized antenna, but a higher gain, smaller beamwidth yagi model. This was mounted on a dual rotator arrangement, to provide elevation and azimuth movement. It provided a much stronger received signal than the fixed option, but of course it needed to be continuously moved to follow the satellite as it traced its arc across the sky. There were even computer programs that would automatically turn the rotators, based on information about the satellite you fed in earlier.

I pondered my choices, and compared them to my current needs and resources. Obviously, the rotating method would provide the best coverage in borderline circumstances, and allow the most data to be squeezed from each pass. On the other hand, someone needed to make sure the rotators were turning the antenna correctly—it didn't sound like this was something that would occur automatically while I was at work, at least not without a whole lot of set-up work on my part. Besides, I really didn't care what the weather looked like when the satellite was down near the horizon—I wanted to see the picture mainly when the satellite was right overhead, which was when the turnstile antenna did its best work. The deciding factor had to do with simplicity and cost. I found that I could put up a turnstile antenna for about one-fifth the price of a yagi/rotor combination, and it looked like I could get it assembled and mounted right away.

Once I decided on the antenna I needed,



the choice of manufacturer was obvious. I had come across a catalog from Woodhouse Communications, in Plainwell, Michigan. Woodhouse has a complete line of antennas, all designed for various types of APT reception. I sent a check off to Woodhouse, requesting their APT-2CP turnstile antenna.

I received the APT-2CP about a week later. As soon as I opened the box I was pleased with the purchase. The Woodhouse folks produce a special line of antennas, and they obviously take great pains to do it right. The vertical boom of the antenna is a piece of one-inch 6061-T6 aluminum tubing. Holes are drilled through the boom for the elements—no U-bolt arrangements here. The 18-8 stainless steel solid rod elements are pre-tapped for the stainless hardware that will hold them in place—no self-tapping screws or hose clamps. The baluns are true coaxial baluns, not ferrite bead types. The balun blocks are machined from HDPE plastic for UV stability and strength. Every part of the antenna, right down to the Ampenol connectors and Belden cable, is real quality stuff.

Setting up the APT-2CP

Assembling the antenna was fairly straightforward, and was done in under a couple of hours, including time for a break. The instructions give some hints on how to support the antenna with a couple

of sawhorses; this made construction quite easy. I had started the project in the early evening, and by the time I had the antenna ready to go up on the roof it was already dark. I decided to put the project off until the next day, but I did hook the APT-2CP to some coax which I tossed through the window into the shack. I didn't get around to mounting the tripod on the roof until a couple of days later, but in the meantime I found that my satellite passes were now at least twice as long—with the antenna still sitting on the ground!

I finally got the tripod mounted, and mounted the antenna on a piece of mast with the supplied stainless steel clamps. The only advice given concerning the location of the antenna had to do with maximizing the "horizon." In other words, get the antenna as high as possible, away from and above any obstructions such as trees and chimneys. (It is recommended that the turnstile not be side-mounted on your tower, and not below your beam!) Once it was on the roof I found that my passes improved even more, and I was able to get full screen images with little problem. In addition, since the antenna was fixed and omnidirectional I didn't need to mess with it at all—I just let my R139 receiver switch on the tape recorder when a satellite was going over, and collect the passes for me so I could demodulate them and review them at the end of the day.

As I collected more and more images, I found that I got even pickier and pickier. I began to notice that there were still a few patches of "snow" at the beginning and end of each pass. The point where the satellite signal was the weakest looked like it could still use some improvement.

Improving the picture

I knew that receiver preamps were available, and that this might help improve my situation. I also knew that a preamp could actually degrade the system's performance—especially if there were a lot of strong signals around. I was somewhat near an airport, so I figured that I might be hit with aircraft transmissions, but I didn't have an excessive amount of public safety or commercial two-way traffic around the neighborhood.

My main concern was that I had been too cheap to go out and buy a quality piece of coax for the turnstile. I had used a 75-foot piece of RG-8 that I had previously used on HF, and I worried that there might be too much loss in it. I weighed the options, and figured that the preamp would be the way to go. Since I was using the Hamtronics R139 receiver, I ordered an LNG-137 preamp from Hamtronics.

The LNG-137 is similar to the LNG-144 preamp used in repeaters and for weak signal work, but tuned specifically for the 137 MHz weather satellite band. It comes preassembled, and requires a +12 VDC supply. (Hamtronics does sell a phantom power kit to allow you to run the 12 VDC up the coax, but I didn't want to mess with building up the isolators on each end. I simply ran a piece of insulated bell wire up to the antenna, and used the coax ground for -12 VDC.) I mounted the LNG-137 on a small (3" x 3") piece of aluminum stock, and mounted it to the mast below the turnstile. I made up a small jumper with the proper BNC connectors, and taped and caulked the unit with silicone sealant.

"As I collected more and more images, I found myself getting pickier and pickier."

Testing with the preamp in-circuit showed improvement at the very beginning and end of each pass in the form of fewer of the black and white "dropouts." So far I haven't noticed any evidence of any of the problems associated with too much gain—intermod products, oscillation, etc. However, in my case, the use of the APT-2CP antenna (designed specifically for 137 MHz) as opposed to a broadband antenna will limit the strength of the out-of-band signals that are passed to the preamp. And the preamp, being tuned to 137 MHz, will favor those signals over out-of-band signals, as well. (If intermod signals do become a problem, I know I can add even more selectivity with a helical preselector, tuned to 137 MHz.)

The Hamtronics LNG-137 preamp and the Woodhouse Communications ATP-2CP turnstile antenna have proven to be a very straightforward, low cost approach to weather satellite imaging. The ATP-2CP is available from Hamtronics, Inc. (716-392-9420) or directly from Woodhouse Communications (616-226-8873).

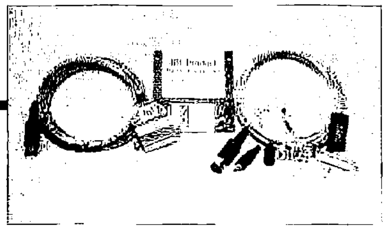
JBI Universal Radio Interface Kit

A great first-time project!



Shane P. Brady WB2WPM
34 Rosewood Drive
West Seneca NY 14224

You just can't beat having your radio talk with your computer for keeping your log straight and for contests, for passing on information such as time, frequency and mode, but obtaining a circuit board for such projects and even getting parts has been challenging. Lots of ideas have appeared in various publications for home-brewing your own interface, and of course you could purchase your radio's manufacturer's interface from them. Unfortunately, most OEM interfaces are in the $100+ category!

"Would I buy another one? Yes—that's exactly what I did."

For six years now, my station has had my Kenwood TS-450 (and before that the TS-440) interfaced with my computer logging program, Log-EQF. While at Dayton this year, I picked up a new IC-706. As I walked around with my new purchase, I was contemplating how to do the interfacing, knowing how lost I would be without a computer talking with my new radio. It just happened that I was at the Log-EQF booth when I noticed the interface they were using—a JBI Universal Radio Interface. Before leaving the booth I had the opportunity to meet John Bechtoldt, the owner/developer of the interface, who had stopped by to say hello. John told me that his interface worked FB with the new IC-706. When he told me the price, I was sold!

The JBI Universal Radio Interface Kit will interface virtually any modern radio (with computer interfacing capabilities) to a standard RS-232 port. This includes just about all the Kenwood, Icom, Yaesu, Ten-Tec, and even the Heathkit SB-1400 radios. While the interface is a stand-alone addition, a few radios do require some internal modification. This you must do yourself, and is not part of the kit. When ordering the kit specify which radio you have so the appropriate cable and plug will be included. The rest of the kit is universal.

About 10 days after ordering, a large brown padded envelope arrived. I was rather surprised at how few parts there actually were. Aside from some capacitors, resistors and diodes, there is only one IC to round out the electronics package. The remaining items are a PC board, DB25 female connector, multi-conductor shielded cable and, depending upon which kit you ordered (Kenwood, Icom, Yaesu, Ten-Tec, Heathkit), the appropriate plug to match your radio—plus a very nice DB25 die-cast hood which eventually will hold all components!

Assembly

Assembly is smooth and quick, and could be a perfect first-time project. The instructions are straightforward, and include illustrations of how the finished PC board will look for each radio. The assembly instructions start off by having you insert the PC board in between the two rows of pins of the DB25 connector, and then soldering them in place (there are only seven pins which actually require soldering). As you are led step by step through assembly, you'll be told to skip certain instructions for certain radios, and to complete the steps for *your* particular radio. Depending upon which radio you are interfacing to, you may have an extra capacitor or resistor left over. Remember, this is a universal interface so you get all the electronic parts for *all* the various radios.

For installing components, the PC board has been properly lettered so you know which component goes where. The large illustrations provided take any guesswork out of where a capacitor or resistor belongs. The illustrations even show the position of the "banded" ends of the diodes, so you can't install them backwards.

The 16-pin IC is installed just about last; it's static sensitive—there's a warning to that effect in the instructions. Caution should be taken that you and your surroundings are all at the same electrical potential, so as not to destroy the chip with static. This installation does not use a socket, so you must solder all leads directly to the board. You shouldn't run into any trouble as long as you don't apply too much heat or make any solder bridges.

One final step: Before putting the assembly into the die-cast hood, attach the shielded cable to the PC board. This is the only place I had any reservations as to which wire went where. The instructions are written around a four-conductor shielded cable. The IC-706 only uses two conductors. A two-conductor cable was supplied with my kit, but wasn't mentioned in the instructions (I have since spoken with John Bechtoldt, and he informs me that this modification to the instructions has been addressed). With the cable wires soldered into the proper holes, it was time to button up the hood.

There *was* one personal modification. Experience has taught me to take the precaution of installing toroidal (ferrite)

cores on all radio and computer cabling in the shack, usually one core at each end of a cable. This step has eliminated the annoyance of inter-equipment interference, and I recommend it to everyone. After putting the halves of the hood together I put a couple of turns on a toroidal core, locating it up close to the hood, adding another core at the free end of the cable. The final step was to install the 1/8" miniature phone plug, which mates with the radio, on the free end of the cable.

Features

JBI also includes a 3-1/2" disk containing a number of DOS programs for rig control, so you will be able to test things right away. Having Log-EQF already on my computer, I used it as my test software. Anyone who has built anything knows the anxiety and dread just before adding power to a project to see if it actually works. I attached the interface to the computer and the radio, turned them on—and the logging program proudly announced it was talking to an IC-706 and showed the appropriate frequency and mode. A spin of the frequency dial and the computer followed along. Success! I was very pleased with the results: no interference, no hesitation—everything worked as expected.

One of the nice features of the JBI interface is that it requires no external power. Next to my Kenwood radio sits the Kenwood interface box, complete with its 12 VDC power plug that I've used for a number of years. Any time I can eliminate some congestion at the operating position I'm all for it, so it was only another week before off went another order to JBI—this time for a Kenwood interface kit. The second kit was identical to the first, with the exception of the six-pin DIN plug that matches Kenwood radios. Assembly was completed on this interface in less than half an hour. It too worked the first time and has performed flawlessly since. It is so convenient not to have that extra power lead running around the back of the station; the old Kenwood interface box, which required the external power supply, will be on my table at the next hamfest.

Currently, JBI Products and Technologies offers their Universal Radio Interface Kit three ways. The first is the interface kit, a genuine bargain, currently listed at $29.95. Manufacturers' interfaces run three to five times as much. Those who are leery of soldering a couple dozen connections may purchase the interface completely assembled, for a current list price of $45.00. The final option is an assembled interface but with the addition of a CW keyer option, at $59.00. The CW keyer option allows many logging and contest programs to key the radio via the computer keyboard. (Shipping and handling are not included in the above prices).

The instructions would be nicer if they were organized straight through for one radio, instead of skipping paragraphs for radios you aren't concerned with, and it would be nice to have included instructions for adding the CW option on your own—but if you want to add the option it really isn't that difficult. Most software programs such as CT and Log-EQF include the instructions for the small keying circuit, which only requires one transistor and one resistor. There is plenty of room in the DB25 hood for this CW mod. I recommend that you spend the extra five minutes on it.

I guess the final test as to would I recommend this kit would be, would I buy another one? Yes—that's exactly what I did.

For details and ordering information, contact: JBI Products and Technologies, 1418 South Yale Drive, O'Fallon IL 62269-2738. 73

NEVER SAY DIE

Continued from page 23

they say? Or are you going to fight back, educating yourself about your cancer and the alternatives open to you?

My advice, which I know most of you are going to ignore, is to do two things. First, do your best to make sure that you don't get cancer. I'm now convinced that cancer is 100% avoidable if you educate yourself by reading the books on health which are on my recommended book list (available from Radio Bookshop). Read, then make changes in your thoroughly ingrained habits which are slowly killing you. If you'd rather die than change, fine—you will. Second, if you don't change so you can avoid cancer, once it hits you can get my reading list and belatedly do your homework. Maybe by then you'll be ready to change your habits. Read the books by Drs. Comby, Wallach, Huggins, Batmanghelidj, Coca, Douglass, about Essiac, L214, and so on.

If you keep your immune system strong you aren't going to have cancer, heart trouble, and any of the chronic illnesses which beset about 99% of older people.

Build This 6m Attic Antenna

A simple stealth antenna project.

Marty Gammel KAØNAN
1703 Hewitt Ave.
Saint Paul MN 55104

A local ham, knowing that I love to make different types of antennas, asked if I could make a shortened 6 meter vertical dipole for him to use in his condominium. Due to his covenant restrictions, his ham antennas have to be indoors and out of sight. I had been doing some reading on helically-wound antennas and told him to give me a week to get the bugs out of the design. With just over eight feet of height to work with in his crawl space, we didn't have to shorten the antenna very much. I came up with a seven-inch spacing between turns so that the antenna would not have a lot of inductance.

The problem with making a helically-wound antenna is that to figure the length of the dipole you must add about 5% to make up for the inductance created by the coil. Also, you'll have less bandwidth with a more compressed coil winding. *The ARRL Antenna Book* states that there are no exact, predictable results when winding shortened antennas. Wire diameter, coil diameter, and compression of the coils all interact with each other.

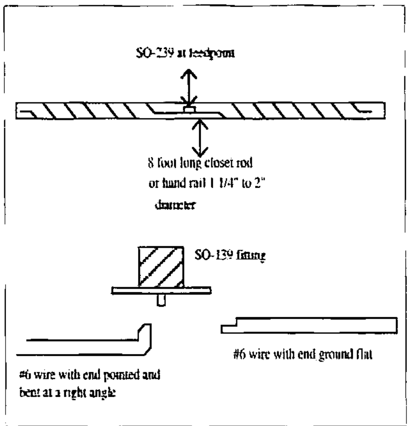

Fig. 1. Shortened helically-wound vertical dipole for indoor installations in your attic or crawl space. (Drawing not to scale.)

This antenna covers the 52 to 54 MHz portion of the 6 meter band. It has an SWR of 1.3 or less, with a smooth SWR curve.

My design is built using a piece of fir closet rod from the local building supply, and some #6 solid copper wire of the type used in wiring houses. The only other parts were an SO-239 panel-mount fitting for the feed point and a couple of screws to attach the SO-239 to the closet rod. I knew that a quarter-wave section of RG-59 coax for a balun would also be needed, to match the 72-ohm dipole to 50-ohm coax.

"With just over eight feet of height to work with in his crawl space, we didn't have to shorten the antenna very much."

OK, let's build it!

I started building this antenna by cutting the #6 solid copper wire into two equal pieces slightly longer than needed, to allow for fine-tuning the antenna. This antenna was planned for use in the FM section of the 6m band, so a 57-inch length was good to start with. Using my bench grinder, I ground one end of one piece of the copper wire to a taper to fit the center terminal of the SO-239 fitting. Then I ground one end of the other piece of copper wire flat to create an end that

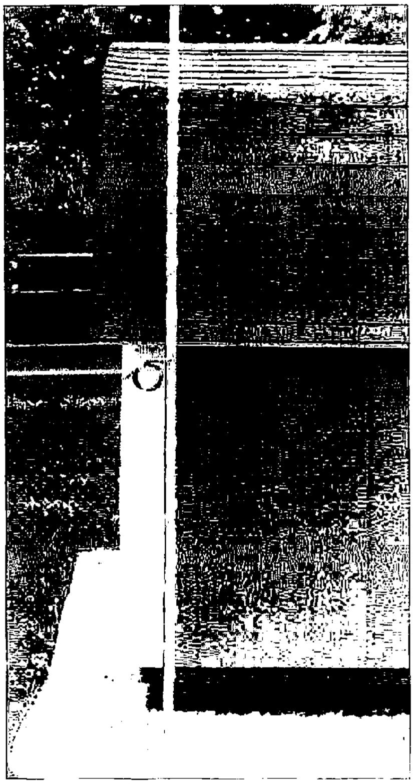

Photo A. The completed 6m attic antenna.

would be more easily attached to the flat surface of the body of the SO-239 fitting. I enlarged two of the SO-239's four mounting holes to ease attaching this fitting to the center of the closet pole. Bend the tapered end of the wire at a right angle to make a neat connection to the SO-239 fitting. Get out your soldering gun and flux to attach the ends of the wire to the SO-239 fitting. This will require a *lot* of heat; my gun is a 350 watt model and was just big enough. Once you have attached both of the wires soldered to the SO-239 fitting, allow it to cool completely before cleaning the excess flux off the surfaces.

Winding the antenna

Now comes the tricky part. I had my wife hold one end of the closet rod and wire while one of my sons held the other end, leaving me with both hands free to wind the wire tightly on the closet rod, using the width of my hand as a guide. I taped this end down before winding the other half. When I was satisfied that the two sides looked equal, I taped this side to the rod, leaving at least six inches straight on each end for tuning the antenna.

Next, make a quarter-wave line section of RG-59 coax to change the 72 ohm impedance to a more usable 50 ohm impedance. Most RG-59 coax has a velocity factor of .66 or .79. The formula found in most ham radio books is 249 divided by the frequency in MHz times 12 for a quarter-wave length in inches. RG-59-A foam coax with a .79 velocity factor is what I had on hand, so my line section was just over 45 inches long. I stripped the ends and installed a PL-259 fitting on each end of the coax with UG-176 type reducers. I wound the quarter-wave line section into a coil, taped it together (see **Photo B**), and installed it at the center of the antenna.

Tuning the antenna

I tested the antenna under conditions similar to those where it would be used, taking care to keep it away from metal objects and other dense masses which might detune it. Using an SWR bridge capable of working at 50 to 54 MHz, I took readings at each end of the desired frequency of operation. Using diagonal cutters, I trimmed the same amount off each end of the antenna, rechecking the SWR after each cut until I had a good match. I ended up with 55.5 inches on each side of the shortened dipole. The match on my antenna was 1.25 at 52 MHz and 1.1 at 54 MHz, with a dip to 1.05 at 53.5 to 53.75 MHz. I used a file to smooth the dipole ends to prevent a corona effect.

Builder's notes

You may want to paint or varnish the wooden rod before construction to help seal the surface against humidity and to keep it from warping. If you can't find #6 bare copper wire you may use #8 wire instead, or copper tubing of about the same diameter. Try to leave at least six inches clearance at each end of the dipole to avoid detuning the antenna. The reason I didn't use a torch to attach the #6 solid copper wire to the SO-239 fitting was that the heat of the torch would damage the insulating section of the fitting.

Readers who have questions about this antenna may write to me at the address above, including a #10 SASE, and I will answer by return mail.

Parts and Tools

- 8-foot fir closet rod 1-1/4 inches in diameter (this can also be a larger size of handrail)
- 114 inches of #6 solid copper wire
- SO-239 panel mount fitting
- 2 PL-259 fittings, with UG-176 type reducers for the balun
- RG-59 coax, 40 to 48 inches long, depending on the coax velocity factor (see text)
- Large diagonal cutters or a hacksaw (to cut the wire)
- Solder and flux
- Good hefty soldering iron or propane torch
- Screwdriver
- Electrical tape
- Grinding wheel (or use a file)

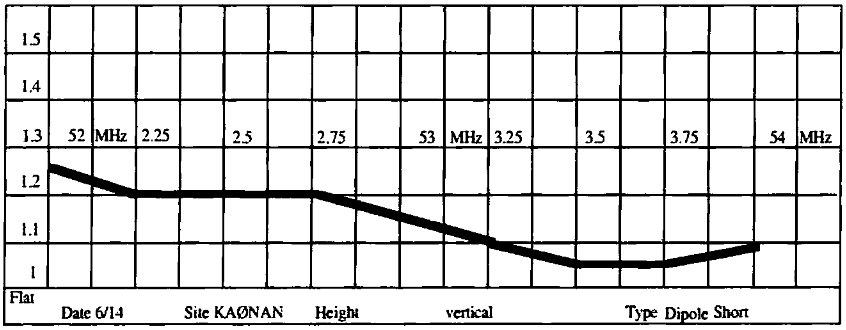

Fig. 2. SWR curve. Please use an SWR meter designed for use with accuracy at these frequencies.

Circulators, Anyone?

Keep the traffic flowing.

Byron Mobus W6OIU
3099 Twin Oaks Rd.
Cameron Park CA 95682-8517

I answer my phone and the manager of the site where our repeater is located tells me that the site is being rearranged. All of the amateur repeaters are to be relocated into one building—the one where our repeater has been located since 1947. Under the new arrangement, the six amateur groups will be responsible for the upkeep and operation of the building, including sharing the costs and electricity. We've had a free ride for many years, but financial realities are about to catch up with us.

Our repeater, W6AEX on 147.27 MHz, is owned and operated by the Society of Amateur Radio Operators (SARO), and the late owner of the mountaintop, Tom Bayley W6NQJ, was a longtime member. Tom made provisions giving us use of the site for as long as the club wanted to have a repeater. We were located in the smallest building on the site, with two commercial operations; one on low band and the other in the microwaves. There was no apparent problem with interaction between the equipment in the building, so we operated with a duplexer and a single antenna on the tower.

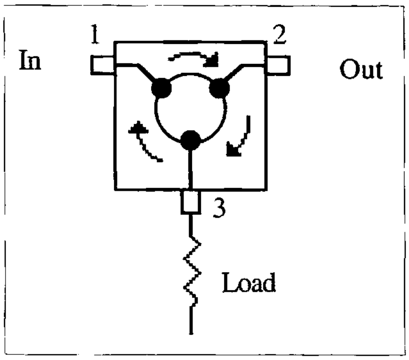

Fig. 1. Single-stage isolator.

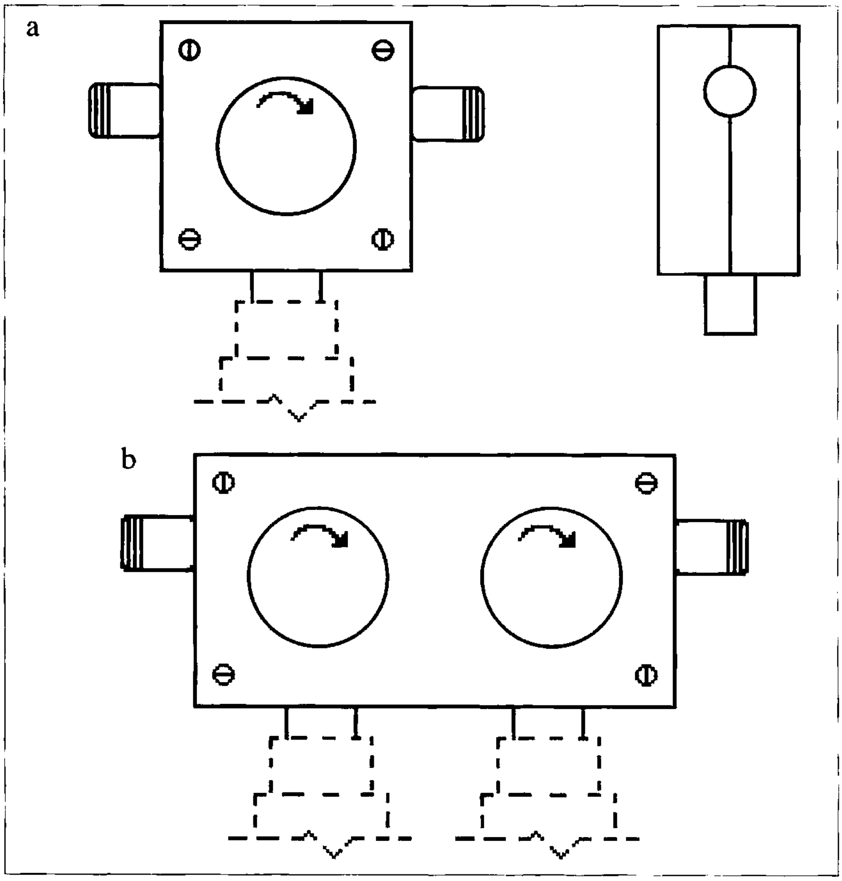

Fig. 2. a) Single-stage isolator; b) Dual-stage isolator.

Under the new regime, there would be several repeaters in the 2 meter and 70 cm bands all operating together in the same building and on the same tower. In an effort to streamline the operation, several big changes were to be made to the equipment to minimize interaction and to keep the noise floor as low as possible. There would be common receive antennas with distribution and amplification to the appropriate receivers. Each transmitter would have its own antenna. One major change was the addition of circulators to the output of every transmitter.

What are circulators?

Circulators? What are they? As a former communications technician for a major oil company, I have maintained microwave equipment that used

circulators, but they never broke so I never paid much attention to them (my philosophy is: "If it ain't broke, don't fix it!"). I started looking around for information on circulators and found less information available on them than on duplexers, which means it's pretty scarce. A friend had a 250 watt circulator for the 150 MHz band which he made available, so I set out to learn what I could about their operation.

A circulator is a device with three or more ports in which RF energy is conducted in one direction with little loss, but exhibits a high attenuation in the opposite direction (**Fig. 1**). There are single-stage and double-stage circulators (**Fig. 2**), your choice depending upon the amount of isolation and insertion loss you require. This is done by arranging ferrite material to provide a high magnetic field through the RF conductor.

RF energy introduced into port 1 is transferred to the antenna at port 2 with more than 30 dB loss to port 3, which is terminated with a dummy load. With 100 watts at port 1, almost all of the power is available at port 2 and less than 0.1 watt goes to the dummy load. Any power returned from the antenna by either an unbalance or the presence of a close-by high power transmitting system is circulated to port 3 and the dummy load. The presence on or near the site of a commercial FM transmitter with an effective radiated power of 250 kW to 500 kW can present an appreciable amount of power to the output of a communications transmitter.

A circulator is a little like a traffic circle with several streets coming into it. As you (transmitter output) enter the traffic circle (input port) en route out of town, the traffic is circling in one direction. You circle in this direction until you reach the next street (output port), then you exit. Traffic (reflected power, received signals, etc.) entering the traffic circle from the street you exit on moves in the same circle direction to the next street where it exits and enters a parking lot (dummy load). This traffic could be from out of town (received signals), or even returning traffic (reflected power) turned around by a problem down the street such as a bridge out (broken coax) or a tree down (shorted antenna). The orderly flow of traffic is ensured by the police (magnetic field) enforcing the law.

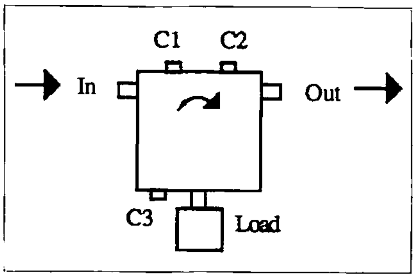

Fig. 3. Field-tunable circulators usually have three tuning adjustments.

Tuning

Field-tunable circulators usually have three tuning adjustments (**Fig. 3**) and the unit is tuned by using a very accurate signal generator and spectrum analyzer or a network analyzer (**Fig. 4a** and **4b**). A 6-10 dB pad is added to the test setup to minimize VSWR reflections in the test equipment. The signal is sent into port 2 (output) and measured at port 1 (input) with a dummy load on port 3. C3 is adjusted for a minimum transfer. The generator is then hooked to port 3, measured at port 2 with the dummy load on port 1. C1 is adjusted for minimum. The generator is then hooked to port 1, measured at port 3 and the dummy load on port 2. C2 is adjusted for minimum. Finally, the generator is hooked to port 1, measured at port 2 with the dummy load on port 3, and the insertion loss is measured.

The circulator I had was tuned to around 160 MHz with no provision for tuning, so I took the covers off. There were pieces of iron attached around the outside of the magnets and when they were removed, the tuning frequency dropped to the 140 MHz range. By careful addition of pieces of iron around the outside of the magnets, the unit was tuned to 147.27 MHz. Unfortunately, when the forward loss was measured, it was around 3 dB, which probably explains why the unit was discarded in the first place.

The unit was further dismantled and I found a triangular brass plate mounted between two big magnets with a connector attached to each apex of the triangle. This was sandwiched between large magnets with heavy iron covers. The ferrite material was badly broken, probably from being dropped, possibly accounting for the poor performance. An identical circulator was located and the tuning procedure was used to put it on our frequency. This time the insertion loss was only 0.2 dB.

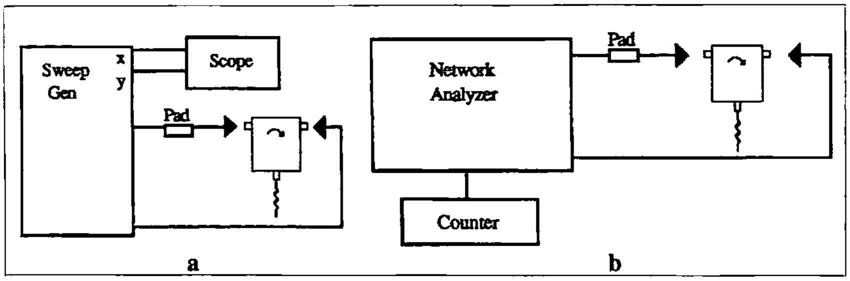

Fig. 4. The unit is tuned by using a very accurate signal generator and spectrum analyzer (a), or a network analyzer (b).

It was installed, along with a cavity, on our repeater. Ferrite isolators are subject to certain nonlinearities and may conduct or generate weak signal harmonics. To protect against second and third order intermodulation harmonics, a low-pass second harmonic filter or cavity is used between the isolator and the antenna. At microwave frequencies, circulators are used instead of duplexers. A circulator might be used at lower frequencies if the isolation is adequate, depending on the transmit and receive frequency separation, but the cost difference between a duplexer and circulator would then become a factor.

In the meantime, an isolator was ordered tuned to our frequency and power, and when it was received it was substituted for the borrowed unit. With other improvements—better grounding, tower bonding, rack bracing and painting—the site looks better and the repeater appears to be working better. At least, there has been no apparent degrading of the repeater from the addition of all of the other equipment in the building.

Hams on the Radio Information Highway, Part 2

How you can easily find and start using Usenet newsgroups.

Jack Heller KB7NO
712 Highland Street
Carson City NV 89703
jheller@sierra.net
CompuServe 72130,1352

Last month I told you about my discoveries on the World Wide Web (WWW) portion of the Internet and about getting hooked up to do the same yourself. I think the number one reason the WWW so intrigues people is that once you get the hang of it, it's easy to move from site to site and find treasures in ham-related up-to-date information. This month, we are going to check out one more part of the Internet where hams have set up house, and I'll to show you how easily you can do it.

Let's explore the Usenet newsgroups. You are not alone if you have heard the name "Newsgroups" but aren't sure exactly what they are. The easiest way to get the picture is to compare it to a forum on CompuServe, America OnLine or one of the other major on-line services: People with similar interests gather and answer each others' questions, or just chat.

One way to imagine what the newsgroup world is like would be to assume that your town has five groups of people, each group with a different interest; also let's say your town has five repeaters and all these groups consist of hams.

It would be pretty simple to assign each group a repeater and a time to get together. This could work. I have never heard of it, but even if it were put into practice, it wouldn't compare to the possibilities of the computer bulletin board or Internet.

Where we spoke of five special interest groups getting together, that was OK, but what happens when there are several hundred—or several thousand? The "thousands" number is the extent covered by the Internet newsgroups, and they reach worldwide. Although only a small part of that is devoted directly to ham radio, many other areas hold related interests for everyone.

Let's look at what is found in the ham radio newsgroups and the basics of getting in on the action. When you get this under your belt, perhaps you'll feel quite comfortable exploring the rest of the Internet. To give you an idea about which newsgroups are ham related, here are a few of the newsgroup names (think of them as addresses):

rec.radio.amateur.antenna
rec.radio.amateur.equipment
rec.radio.amateur.space
rec.radio.amateur.misc
rec.radio.amateur.digital.misc
rec.radio.amateur.homebrew
rec.radio.amateur.policy

The names of these newsgroups are chosen carefully so they will be intuitive to you. You probably can understand what most of the above means with no explanation. The "rec." simply stands for recreation.

There are several other basic groups. For instance "comp" stands for computer and "sci." refers to science. Within the ham newsgroups, anything with a "misc." is obviously a catchall and "policy" covers subjects like no-code and other perennial topics.

Now the question is, "How do I get these newsgroups with the software we described last month?" I must admit I was a little intimidated when I decided to write this using a brand-new version of a program that is still in its test and development stages. The company (Netscape) has experienced some hitches during the development, but I think this version (2.01) does the trick.

I have heard complaints about 2.0, yet I used 1.2 prior to this for most of a year and it was excellent. As of this writing, there are already upgrades available for download. It is at least as difficult to keep abreast of the changes on the Internet and its component software as it is to attempt to explain how to program a new HT. (I keep my manuals handy for programming those "intuitive" little machines.)

Netscape 2.01 comes with a raft of bells and whistles that I was sure would be difficult to understand, but the folks at Netscape did something I really like that takes the edge off the learning curve. They do not at this time have a help file built into the program, but if you go to the "Handbook" button and

click on it, you will be connected directly to the Netscape homepage.

There you will be introduced to a voluminous manual that you can scan through and/or download and print for yourself. It comes in sections, so I printed the part needed for using newsgroups and E-mail. This current documentation is an improvement over past instructions furnished by the company. One thing Netscape makes possible is the "Save as" feature. You can select "Save as" from the file menu and specify the directory in which you want to store the Handbook, or any web page, and you will have it to read or print offline. You can open your saved file into Netscape as long as it can find "windsock.dll" or you can import it into a word processor.

New adventures

Last month, I mentioned that the *Yahoo!* search engine will also explore the newsgroups to aid you to find those to fit your interests. I suggest that if you wish to do this and you have found your way to the Netscape search engine page by clicking the "Search" button, you just need to go a few steps further.

If you will scroll down Netscape's search engine page below the prominent choices of five search engines, you will discover lines you can click to go directly to such sites as *Yahoo!*

Click on *Yahoo!* and it will look similar to **Fig. 1**. You will notice that to the right of the box where you would type in "amateur radio" there is a line that reads "options." When you click there, a list will appear that includes "newsgroups." Select that and your search will give the results of a newsgroup search. You have conquered another area of the Internet.

Here are a few pointers to help you get started on the road to success. First, you need to know there are three basic screens you are going to use as you communicate on the Internet: The Web Browser screen, the Mail screen and the News screen (for newsgroups).

The Web Browser can be found in the File menu and the other two are available in the Window menu. Also in the Window menu are two other screens; one for Bookmarks (so you can easily return to an informative website at a later date), and another to display E-mail addresses you consider worth keeping.

The newsgroup screen will look like **Fig. 2** when you open it. You will need to have your connection made to your server. Click on the newsgroup in the upper left panel and hit an "Enter" to get the program to access the net and retrieve the news messages for the newsgroups you "subscribe" to. The panel borders allow you to adjust them to your preferences by clicking on them with your mouse.

As you discover more newsgroups that interest you, you will want to add them to the list. You will find "Add newsgroup" in the file menu, and upon selecting it, you'll have a pop-up screen. Enter one of the newsgroups "addresses" (example: "rec.radio.amateur.equipment").

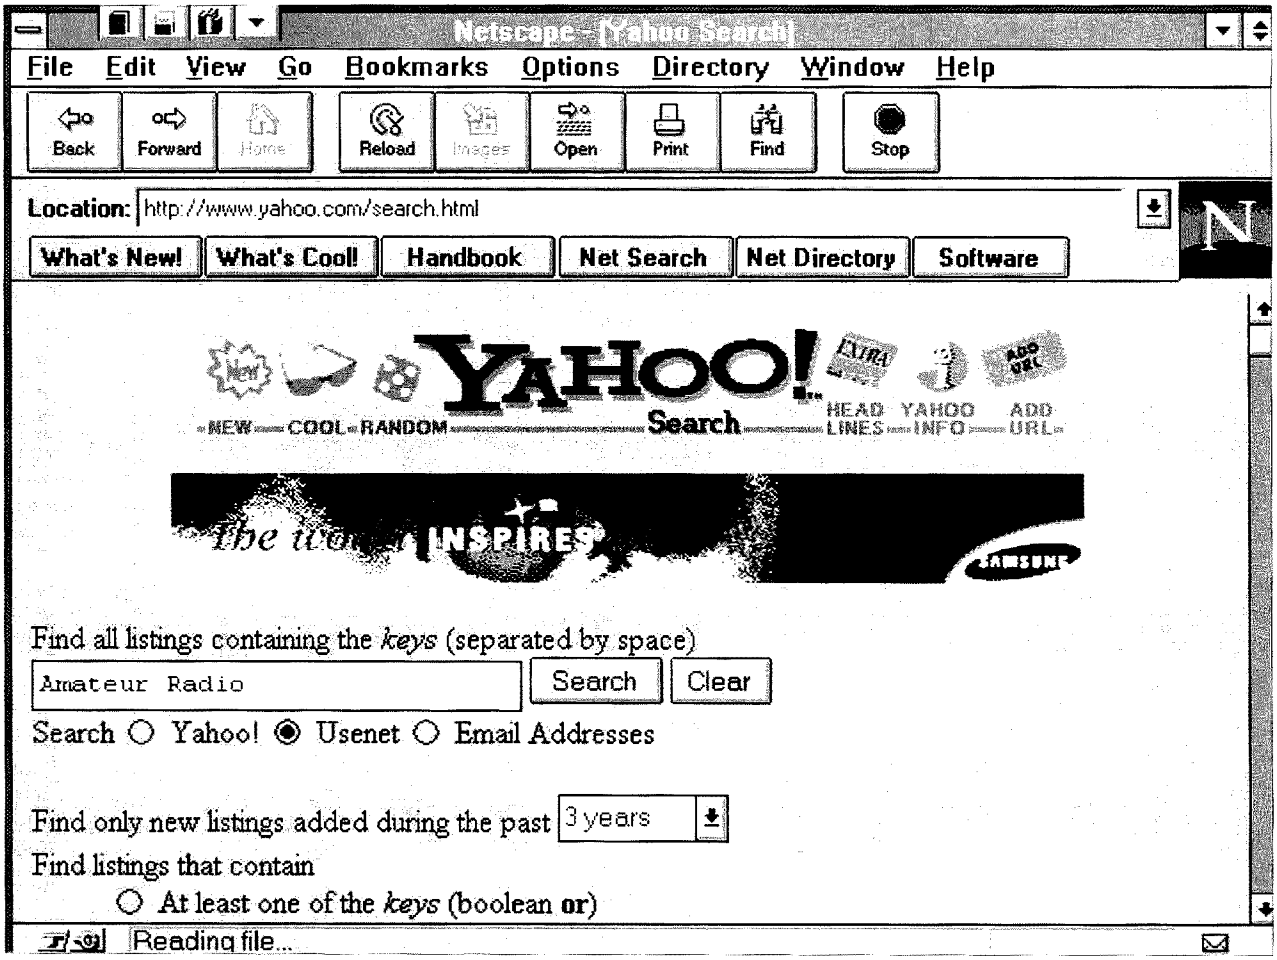

Fig. 1. Search engine (http://www.yahoo.com) with newsgroup choice selected.

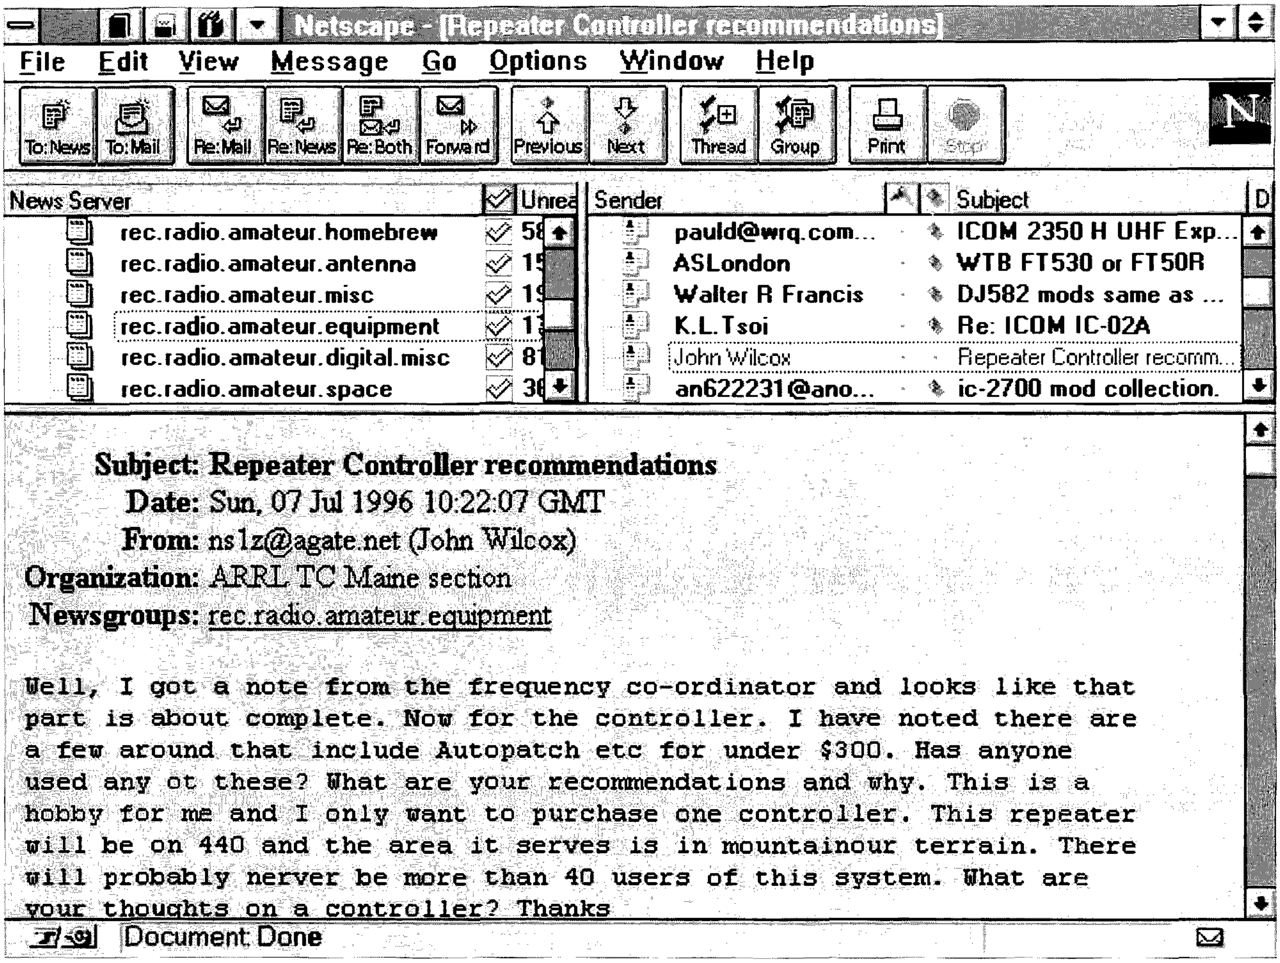

Fig. 2. The upper left panel shows the newsgroups and the number of messages. Upper right are the headers of the articles in the selected newsgroup. Lower panel is the selected message. You can change the panel borders to suit yourself.

Press "Enter" and the program will access the net and retrieve messages. Click on the line you just created in the upper left panel and you will see a list of headers in the right panel. Pick one, click on it, and the message will show in the lower panel. You are on your way! (I noticed a disconcerting thing happening the first few times I did this. When I shut down the program and came back, my freshly installed newsgroup would vanish. After careful study of the Handbook, I found I needed to click *on the check marks* in the upper left panel as seen in **Fig. 2.**) You will also want to study the various choices in the Options menu. They affect what is displayed in the upper left panel.

Now on to the fun stuff. The spirit of ham radio is alive and well on the Internet. One of the great advantages is having a place to go where your area of interest in the hobby can be addressed, and there are numerous hams who come back, sometimes within a few hours, with helpful hints.

You will find messages posted about subjects all the way from old-time radio to high-speed modems and spread spectrum. I even ran across a few queries that I posted a suggestion for. One thing is obvious—the amount of ham activity is such that the message board spans a period of just a few days, about a week. This means the same messages don't appear time and again, and if you need to communicate, you must not hesitate.

As you read the messages posted in the newsgroups, you find many references and often clickable links to web or FTP sites for current information that you may not have come across any other way. One example was a message that contained an easy link to a website containing information about digital mode software. There are numerous such opportunities; you just have to look to appreciate what is available.

Another familiar aspect of ham radio is obvious on the net—courtesy. Every message I've read is positive. No one is derided for asking a "stupid" question. Even when someone of a lower intelligence group posted an offensive profane message, it was handled with utmost politeness and refusal to sink to the level of profanity that had been posted, typical of the ham community.

Yes indeedy—vulgar language does exist on the Internet. What you might see in the ham sections will likely be posted by a non-ham who desires to cause an uproar. The practice doesn't seem to be prevalent, but I don't think there is a way to control childish pranks. Perhaps the Internet sages will come up with a method that would be less disastrous than a government attempt at regulation.

On an upbeat note, you may have enjoyed the experience of having someone give advice over the air that results in an instant fix of an equipment problem. The chances of this happening over the air are slim, due to limited exposure to those who may be able to copy us or have any interest in "reading our mail."

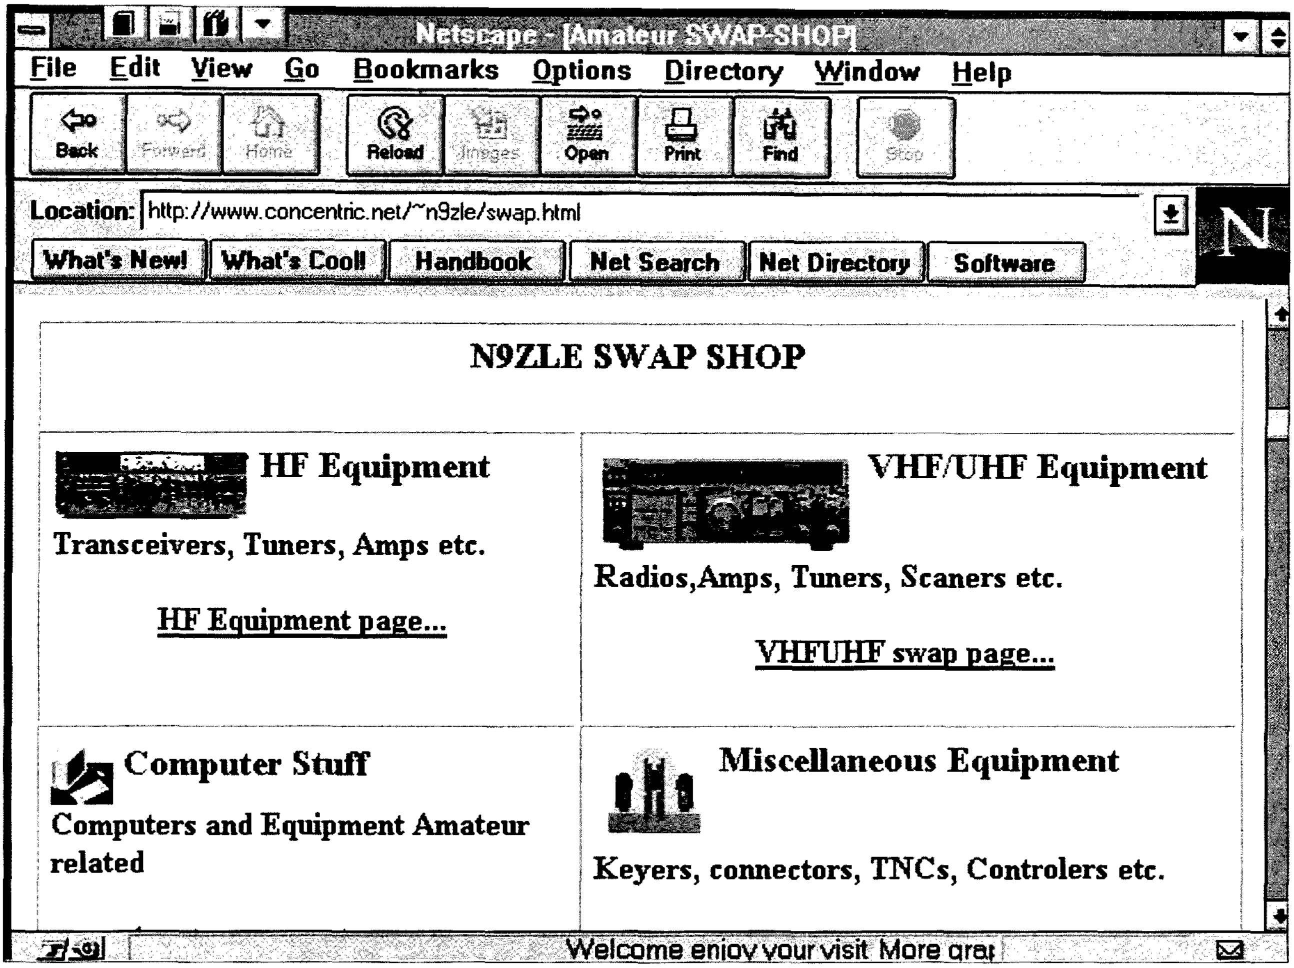

Fig. 3. One of the various swap areas on the net, referenced from a newsgroup posting.

Chances improve exponentially when you talk to a captive audience such as in a newsgroup.

The Internet is one more place where you will find and can join with hams buying and selling equipment (**Fig. 3**). There are several swap areas you will run across (they become obvious) and there is always the chance of striking a good deal. There are many hams looking for equipment that might just be sitting around in your shack.

If the idea of this massive media intimidates you, you are not alone. The number of new folks signing on every day must be astronomical. Quite a few of them, outside the ham areas, are leaving messages begging for E-mail just to see "if it really works." It's reminiscent of the first time on the air for many of us.

Folks who feel insecure with a new medium are justified in their fears, I feel, when they have jumped into an E-mail or newsgroup arena where they feel no common bond. When you, as a member of the vast ham radio fraternity, log onto a ham newsgroup, you are right at home among friends.

73 is accepting manuscripts for the June 1997 Field Day Issue.

If you had a good time at that last Field Day, or have ideas about how to make Field Day a big success, submit your manuscript on a 3 1/2 inch disk, along with a print out and photos, by the end of February, to Joyce Sawtelle, 73 Amateur Radio Today, 70 Route 202 North, Peterborough NH 03458.

NEVER SAY DIE

Continued from page 29

vivid memories of the people behind the cards, many of whom I got to know personally.

Take for instance the KV4AA card. Tens of thousands of hams will never forget Dick Spenceley's machine-like fist from St. Thomas. This card confirmed a contact with me when I was operating from Curacao, where I was visiting PJ3CC, who ran a vacation hotel which included scuba diving and a ham station, sitting atop a cliff overlooking the Caribbean. How could I not go there?

I first got to know Dick when I inherited him as my DX editor when I took over as editor of *CQ* in 1955. It didn't take long for me to find an excuse to fly down and visit Dick and his wife Anna, and to work a little DX with his Johnson KW rig. I also got in some great diving and found a horse to rent so I could ride around the beautiful Magan's Bay area. I rented my diving equipment from Leslie Caron's father, who ran a dive shop there.

One of Dick's friends, another KV4, had a little plane, so I was able to take some marvelous pictures of the island. Then there was the six-pound lobster I speared which provided dinner for the whole Spenceley family.

Well, you're tired of my ham memories, so how about you? Dig into your old QSLs and tell us some stories that they bring back for you. Don't forget to send me a disk copy. No, I won't lose your QSL.

Like the time I visited VK6RU in Perth in 1966 and he whipped out my QSL from 1946. That was during my ham African safari trip, where I continued on around the world after shooting anything that moved in Kenya and visiting Robbie 5Z4ERR in Nairobi. I hope you can get even a fraction as much adventure from hamming as I have. Hey, it's there, waiting for you, but you have to make the first move. The brass ring is out there, but you have to lean way out to grab it. If your QSL file doesn't bring back memories of ham adventures, maybe it's time to kick yourself in the butt. And don't give me any of that "Gee, I can't afford something like that" baloney. Money is easy to make once you know the secret and are able to try a new paradigm. Or is one digm enough for you?

I can point the way, but I can't force you to make changes in your life. Yep, change sure is difficult to make. But the world is constantly changing, whether you do or not, and it's going to leave you behind, fussing about things, but never really doing anything about them. Ooops, there I go preaching again. Sorry about that. The hams with rusted-in attitudes say, "There goes Wayne, bragging again," when I tell about my adventures. The few hams who are still not brain dead say, "Hey, Wayne's right, I *could* do that!"

My $5 book, *Making Money, a Beginner's Guide*, explains the secret. I should charge $5,000 since I know gratitude is one of the least felt of all emotions. The demand for the book has been brisk, as a result of my May appearance on the Art Bell W6OOB radio show, and then its repeat broadcast in August. The nice part for me is that I'm already getting letters thanking me, saying wow, it sure works!

I don't care how old you are, if you make some changes in your life you can get on the air from Fiji and Tahiti too. And Nepal. Or even from a king's palace. Or you can work the world from a farm in New Hampshire, where the air is pure and the living about the best in the whole country. Or both. Heck, why not? Or, let's see, what's on TV tonight. Or is it time to call into that old 75m net? Your choice—adventure or status quo.

Enlightening

How many seconds a day on the average do you get out of your ham shack long enough to look up at the sky, close enough to the sun so some of those UVs get into your eyeballs? And without any glasses or windows to filter 'em out?

Now, second question. How many hours a day do you think the people you're descended from spent a day getting UVs into their eyeballs? Before eyeglasses and windows were invented?

Third question. Would it surprise you to learn that getting those UVs into the eyes is vitally important for your health? That a million or so years of living with UVs has developed a dependency on it for your body?

If I can get you to spring the five bucks for my book list, and then go absolutely hog wild to buy a few books and read 'em, you'll learn a whole lot about what your body needs in the way of food, minerals, water, UVs, oxygen, and so on. Needs, and isn't, for the most part, getting.

I've put in a heck of a lot of work finding some books which are exciting and valuable. What I haven't figured out yet is how to get you to read 'em and start changing your life. Sigh.

So now, in order to ignore the above light news so as not to have to change your way of living (and being sick), you're saying to yourself that there goes Wayne exaggerating again. I know you haven't read the Ott or Lieberman books on my recommended list or you'd have written to thank me. Well, maybe I can get you to check out *Sunlight* by Dr. Zane Kime, ISBN 0-9604266-2-5, $12, 315p, World Health, Box 408, Penryn CA 95663. How does sunlight affect cholesterol, blood pressure, and the immune system? No, I'm not selling the book.

Okay, if you don't care enough about your own health to read it, will you educate yourself a little to help your kids live healthier lives?

Autism, Etc.

The *60 Minutes* segment on autism was interesting. You remember *Rainman*. Did you know that before vaccinations autism was almost unknown? As were hyperactivity, dyslexia, and learning disabilities in children?

Did you know that in a double-blind test the polio vaccine caused twice as many cases of polio as it prevented? According to the CDC, 87% of all polio cases between 1973 and 1983 were caused by the vaccine.

And, oh yes, talking about compulsory poisons, did you know that tests with animals show that they are made much more docile when given fluorides? Like those being added to your water and you're drinking unless you're distilling out the fluorides, chlorine, and other mischief.

Between these compulsory poisons helping to fry our brains, the flowering drug culture and our worst-in-the-developed-world schools, kids' SATs are way down, so they're lowering the scale so it won't look as bad.

If you'll read a couple of the books I recommend you'll learn that sugar and white flour are almost as destructive to your body as they are for your car if you put them in the gas tank. No wonder our police are causing so many problems on their Dunkin Donuts diet.

cold fusion alchemy kit for our budding scientists? (And makes bazillions?)

I was seven when I got a Chem-Craft chemistry set for Christmas. It was beaut! The experiment I remember best was the one using potassium permanganate plus a couple drops of glycerin and then, in about half a minute, the mixture would start bubbling and burst into flame. Wow!

The cold fusion field has developed enough now for a kit to be marketed which would enable experimenters to measure the excess heat generated using different metals and electrolytes. Complete with an interface so a computer could record the data and chart it.

You'd need a small glass cell and a surrounding calorimeter. Hey, if they can sell indoor-outdoor thermometers retail for under $15, that's about all you'd need to measure the inside and outside calorimeter temperatures. I'd supply some powdered metals such as palladium, nickel, and titanium, and the chemicals to make various electrolytes. A wall-wart power supply could supply the current to trigger the reaction. Plus a small motor to stir the electrolyte to distribute the heat evenly. I'll bet the whole kit could be marketed for under $200.

If it were my company I'd be selling refills, plus other kinds of powdered metals such as rubidium, rhodium, and anything else that has a suitable lattice structure for generating excess heat. I'd also start a newsletter for junior researchers, plus include instructions on how to patent your discoveries. This is pioneering territory and the fact is that kids could come up with better and better cold fusion systems.

I'd also look around for a college with one of these newfangled instant mass spectrometers where experimenters could, for a small fee, send samples from their used cells to find out what transmutation products have been generated in the process.

In a recent test using nickel with a lithium sulfate electrolyte in plain water, a cell generated generous amounts of iron, gold, copper, magnesium and chromium ... and, oh yes, heat.

Well, you're probably too busy to be interested in making bazillions anyway, right?

Donor

Perhaps I'm on more mailing lists than you, but I found my mail stuffed with requests for money for political campaigns this last fall. Lordy, the direct mail companies must have made a killing. Those who sent postage paid envelopes got an offer to make a $1,000 donation, but I did ask for some assurance that the candidate would be working for my benefit more than his own, so I included some minor caveats.

Like a campaign promise which would give me a guarantee that I would see some needed changes such as: (1) Term limits for federal judges, plus some guidelines for them, such as a return to the constitution instead of leading the parade for social engineering, as they did with school busing. (2) Get the government and the judges out of religious issues such as school prayer and abortion, which represent still more social engineering. Why are we even arguing about mixing church and state? The constitution was supposed to settle that. (3) The elimination of government confiscation of property through its many agencies. For instance, the property tax effectively makes the owner of property a lessee, not an owner. If you stop paying the tax, you lose your property. If an informant tells the police that you have drugs on your property the police can (and all too often do), without a warrant, break in, plant some drugs, and then confiscate your property. If the IRS decides you owe for taxes they can confiscate your property. I put my life on the line—on the front line—during WWII, but it wasn't for the America I see today. The RICO (organized crime) laws were, as usual, well intentioned. But government agencies have misused them to

The Solder Slurper

Build your own desoldering station—cheap!

Dave Evison N6GKC
153 Park Avenue
Palo Alto CA 94306

Whether you're recycling parts mounted on a PC board or repairing some electronic equipment, you want to remove the parts without ruining either the parts or the board. While there are many professional desoldering stations and aids available, most are either expensive or ineffective. Professional desoldering stations are priced from $400 and up, which is more than most of us are willing to pay.

You'll find the Solder Slurper is equal to or better than most commercial units. It uses off-the-shelf parts you can get at any Radio Shack™ and auto parts stores. And it can be built for under $60, even if you buy all new parts. However, if you get a used fuel pump and parts from your junk box, a first-class unit can be put together for just a few dollars.

The Solder Slurper is designed around an automobile electric fuel pump, associated fuel filters, and a Radio Shack desoldering iron. The rubber bulb originally used by the Radio Shack desoldering iron to create a suction for extracting the molten solder is replaced with a hose, filters and the electric fuel pump. The heated tip of the desoldering iron is placed on the joint to be desoldered, the solder is melted, then the foot switch is pushed and the pump sucks the molten solder away from the joint. The first in-line fuel filter captures the molten solder, keeping it out of the pump mechanism. The second in-line fuel filter further protects the pump by removing the desoldering fumes.

While the pump will work with any 12V supply capable of delivering an instantaneous 6A and continuous 2A, I used a gel cell with a trickle charger. Since the in-rush of current is steep when the pump is turned on, many regulated power supplies will blow fuses. If the supply incorporates a crowbar circuit it may also shut down the power supply. The gel cell battery acts as the power source, with excellent low internal resistance, and easily provides the high starting current.

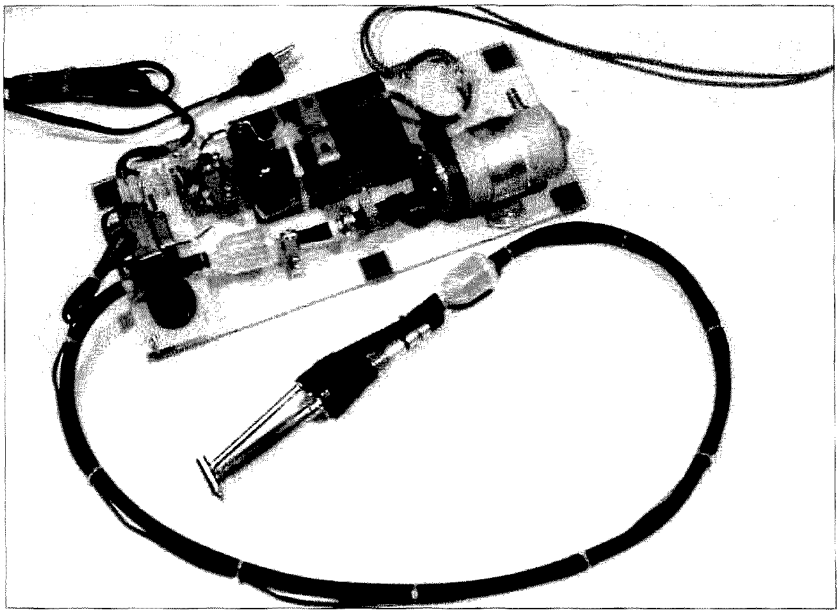

Photo A. *The prototype Solder Slurper.*

The circuit

The charging circuit is designed around a common 12.6V filament transformer and a 15V three-terminal regulator. It is designed to deliver a charging current until the surface charge of the battery equals the charging voltage of the charger (13.4V). The two diodes in the regulator output minimize the discharge of the battery through the charger, should the AC power be removed from the charging unit. The forward drop of these diodes also determines the applied charging voltage to the battery.

Since the Radio Shack desoldering iron is not grounded, a grounding circuit must be added to the soldering iron to protect sensitive parts from an electrostatic discharge. Any one of the three screws fastening the metal iron to the plastic handle will provide an easy way to ground the iron.

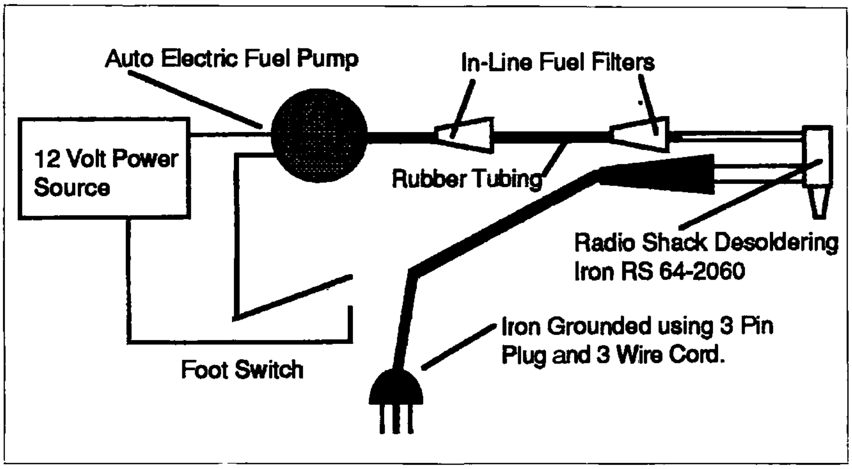

Fig. 1. The system.

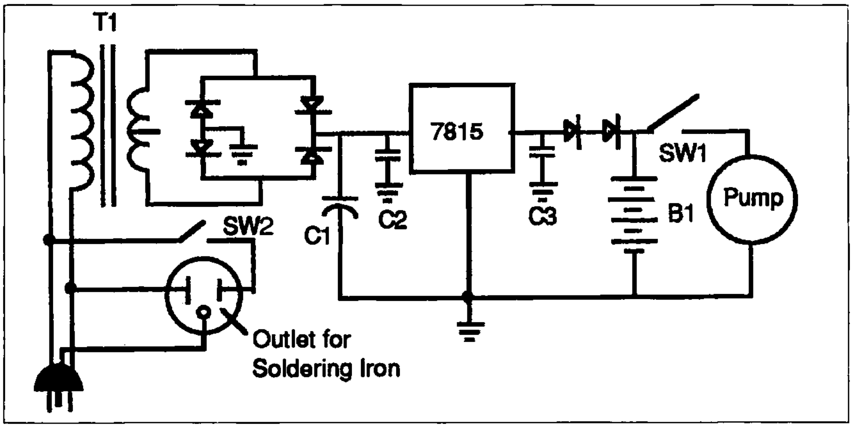

Fig. 2. The gel cell battery trickle charger.

Parts List

Desoldering Iron	Radio Shack # 64-2060
Electric Fuel Pump	Bosch GFP 221 or equivalent
In-Line Fuel Filters	WIX 33011 or equivalent
Interconnecting Hose and Clamps	
AC to DC Power Source	
T1	12.6V @ 1.2A filament transformer (RS 273-1352)
C1	250µF @ 25V
C2, C3	0.1µF @ 50V
7815	3-Terminal Regulator
All Diodes	1N4006
B1	12V Gel Cell Battery, 3Ah or greater
SW1 (Foot Switch)	SPST 10A
SW2	SPST 1A

When connecting the pump, filters, and vacuum hose to the various parts of the unit, make sure you make good vacuum-tight seals. And if you are using a used electric fuel pump, make sure there is no residual fuel or vapor in the pump. Let it run for 10 to 15 seconds to purge the pump prior to extracting solder.

As with any desoldering tool, an accumulation of solder can build up within the hollow desoldering tip and discharge tube of the iron. Heavy build-up can, over time, actually block the discharge tube, so you may have to drill out the blockage.

During heavy usage, the build-up can be minimized by frequently shaking the accumulated molten solder out the hollow tip into an old tin can and by running the pump for a couple of seconds

> ***"A first-class unit can be put together for just a few dollars."***

prior to turning off the iron at the end of the day. Another useful technique to both remove the solder and free the lead being desoldered is to carefully "skate" the tip of the iron on the pad and thereby position the lead in the center of the hole.

Photo A shows the prototype Solder Slurper with the parts mounted on a piece of plastic. While the prototype is ugly, the interconnection of parts is clearly shown. If you put the Slurper in a flashy box, you could sell the units commercially.

The Solder Slurper sure is handy in my small laboratory, and its "Ghost-Buster" look always gets comments.

Columnist Needed

Write a 1250 word monthly column about Mobile, Portable, and Emergency amateur radio operations. Contact Joyce Sawtelle, 73 Amateur Radio Today, 70 Route 202 North, Peterborough NH 03458. Tel. (603) 924-0058.

Audio Filter Alignment Generator

Another piece of test equipment you can build.

J. Frank Brumbaugh KB4ZGC
Box 30 - c/o Defendini
Salinas PR 00751-0030

The vast majority of transmit offsets for CW and SSB have been established at approximately 700 Hz. This is practically an industry standard and is also the offset used in most QRP transceivers, whether they're kits or home-brewed. Therefore, active and passive filters are most often designed to have a center frequency of about 700 Hz and the many circuits found in the ham literature bear this out.

Of course, few if any filters can boast a center frequency of exactly 700 Hz, because electronics is a world of tolerances and percentages, but all such filters will be centered very close to 700 Hz.

There are numerous circuits published for small fixed-frequency audio oscillators, usually Twin-T or phase-shift circuits. But, with tolerances and strays, it takes a lot of "cut-and-try" to get such an oscillator to produce exactly the desired frequency.

"For most hams this will be a junk box project and cost nothing—and it can be constructed in an hour or two."

A much easier way to produce a signal at the exact frequency required to check and adjust an audio filter is to use an audio generator whose output signal is known, accurate and stable. (See "Crystal-Controlled Audio Generator," *73*, November 1995, page 28. Note: There is an error in the schematic. C11 should be connected between the emitter of Q3 and the emitter of Q2.) Although recommended as an accurate and stable generator of signals in the most useful range of 300 to 3,000 Hz, if you only need to trim your filter for a 700 Hz center frequency, this would be overkill.

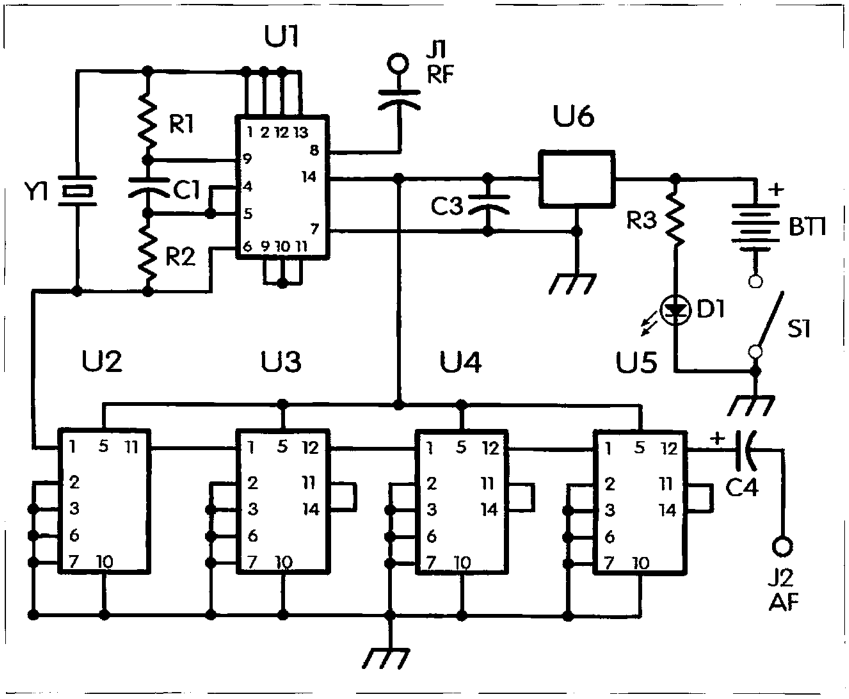

Fig. 1. Schematic diagram for the audio filter alignment generator.

This article describes an even simpler and cheaper audio generator, also crystal-controlled but producing a single frequency of approximately 716 Hz (which is well within normal, even very close tolerance for the usual 700 Hz filter frequency). If this is the only audio frequency you need, you may wish to build this simple project. The output frequency is stable and accurate because it is derived from a crystal oscillator. There will be no drift of the output frequency. The crystal frequency is divided by a factor of 5,000, so the crystal would have to drift 5,000 Hz for the output frequency to vary by 1 Hz. That's *real* stability!

For those hams who need to buy some or all of the few component parts as new "surplus," the cost should not exceed about $5. For most hams this will be a junk box project, and cost nothing—and it can be constructed in an hour or two.

The circuit

In **Fig. 1**, U1 is a 74LS00 quad two-input NAND gate. Two of the gates are connected to form an oscillator controlled by Y1, a common inexpensive color-burst crystal with a *marked* frequency of 3.579545 MHz. The output of the crystal oscillator at pin 6 of U1 is applied to input pin 1 of U2, a 74LS90 configured to divide by five. The output from pin 11 of U2 is applied to input pin 1 of U3, a 74LS90 configured to divide

by 10. The output from pin 12 of U3 is applied to input pin 1 of U4, also a 74LS90 configured to divide by 10. The output from pin 12 of U4 is applied to input pin 1 of U5, a 74LS90 also dividing by 10 to produce the desired output frequency of 716 Hz at pin 12. This 716 Hz frequency is applied to output connector J2 through C4, which blocks the DC voltage at pin 12 from the output connector J2.

The above describes the functioning of the primary 716 Hz audio generator. However, because a color-burst crystal is used, there is a bonus to be derived at no additional cost. The crystal frequency at pins 1 and 2 of U1 is fed through the two unused gates which are connected to form inverters, and is available through DC blocking capacitor C2 at J1, taken from pin 8 of U1. The possible uses of this harmonic-rich signal will be discussed later.

Power is supplied by BT1, a 9 volt alkaline battery, and is controlled by S1, an SPST switch. The 9V source is applied to the input of U6, a 78LO5 voltage regulator which provides a regulated positive 5 volts to all TTL chips in the circuit. C3 bypasses the output terminal of U6 to remove any digital spikes which could affect regulation. The combination of R3 and LED Dl is optional, but it draws only about 3 mA so it is recommended as a reminder to turn the generator off when not in use, to prevent draining the battery.

Construction

The circuit can be built on a piece of perfboard, a general purpose printed circuit board, or "dead-bug" style on a base of any nonconductive material such as plastic or wood. Sockets for the chips aren't necessary, but may be used if you wish. Note: It might be desirable to use sockets for the four 74LS90 chips. I have found a number of these chips, purchased from mail order vendors as "new surplus," which refused to divide. Changing chips in sockets is much easier than unsoldering their pins from a PC board.

An enclosure isn't necessary, but if you do a lot of work with active and passive filters you may wish to build it neatly in a small plastic or metal box, or one made from printed circuit board material.

Operation

Since this is a digital circuit, if the crystal is good and all chips are wired correctly and are in their designated places in the circuit, it will function as soon as power is applied.

If it doesn't work at all, or the output audio frequency is incorrect or unstable, you either have a bad crystal or one with the wrong frequency, one or more bad chips, or something as simple as a wiring error or solder bridge. If you use sockets for the chips, make certain they are in the right sockets *and* are oriented correctly. It will help if you place a dot of white paint on top of each chip at pin 1, and also on the side of the socket at pin 1.

Again, when a simple digital circuit is wired correctly, has all good parts installed correctly, and the proper operating voltage is applied, it will function as designed—period.

Using this instrument

This is a fixed frequency audio generator. Feeding its output into the input of an audio filter while monitoring the amplitude level of the filter output with an oscilloscope or a DMM on a low DC voltage range will allow tweaking the values of pertinent resistors and capacitors for maximum output voltage, resulting in the center frequency of the filter being exactly the same as the generator.

It has a number of other incidental uses as well. It can be used as a sidetone generator. It can be keyed in either the positive or negative power lead as a code practice oscillator, feeding headphones or a small speaker. It can also serve as a signal injector for aligning receiver circuits because the output is rich in harmonics.

Using the bonus frequency

The crystal frequency available at J1, which will be close to but not exactly the marked frequency of 3.579545 MHz, has strong harmonics which fall within or near every ham band from 80 through 10 meters, including the WARC bands. To be useful for calibration checking or as a signal for alignment purposes, these harmonic frequencies must be known accurately.

Measure the frequency at J1, using a frequency counter, then multiply this frequency by each harmonic number from 2 through 8 and note these frequencies for future use.

The signal level at J1 is much too high to feed directly into the antenna connector of a receiver. You can connect a short length of wire to J1 and radiate the signals to your station antenna. Another method is to disconnect the antenna from your receiver and connect a short length of wire to the receiver antenna connector. Drape this wire near the instrument to conduct its signals to the receiver.

Parts List

BT1	9 volt alkaline battery
C1, C2	0.01 µF ceramic disc or monolith
C3	0.1 µF ceramic disc
C4	100 µF electrolytic, 10 WVDC or higher
D1	LED, color optional
J1, J2	Output connectors, your choice
R1, R2	1k 1/4W 5%
R3	2.7k 1/4W 5%
S1	SPST toggle or slide switch
U1	74LS00
U2-U5	74LS90
U6	78LO5
Y1	3.579545 MHz color-burst crystal

The Art and Challenge of Sending CW

When a QSO is so much more than just "RST, QTH, name and 73."

Bob Shrader W6BNB
11911 Barnett Valley Road
Sebastopol CA 95472

With Hand-Key Night coming up on December 31st it's time to get out the old hand key, rubber-cement it to the tabletop and get ready for some good old-fashioned fun-type CW QSOs. Hand-Key Night is a time when a QSO is much more than just, "RST, QTH, name and 73." It's rag-chewing. It's a time to find out what rigs are used; what bands, what type(s) of work done; when the other op was first licensed, radio backgrounds, latest travels, sports, homes, computers, animals, marital status, kids, greatest accomplishments—everything!

Amateurs know their code sending as "CW," meaning "Continuous Waves." It may surprise some newer hams that this means radio waves that have a constant amplitude (strength), and has nothing to do with how long the waves are being generated. The term developed in the earliest days of radio when code transmissions were made only with spark-type transmitters that produced decaying-strength RF "wave trains." When a spark occurred in a spark transmitter, a high amplitude RF ac was developed, at the quarterwave frequency of the antenna, that rapidly decayed to zero. Each half-cycle of the power-line ac developed a spark and RF wave train of its own. Power line ac with a frequency of 60 Hz used in a spark transmitter produced 120 RF wave trains per second. Originally, all radio communications were made using spark-type telegraphic code signals—there was no such thing as CW or radiotelephone.

When constant amplitude radio wave generators were developed and used for radiotelegraphic code, those emissions were termed CW because they were Continuous-amplitude Waves, not decaying spark-type waves. Today, the term CW has taken on the meaning of any type of radiotelegraphic code used in the MF or HF bands. However, the abbreviation "MCW" indicates an audio-frequency Modulated Continuous-amplitude Wave code signal, which may also be used by hams but only in their VHF, UHF and SHF bands.

It's a challenge

Learning to send CW correctly with any type of mechanical or electronic-aided key does not come easily. Many newer hams have never been advised by qualified CW operators, so may never have been shown how to use a key correctly. Proper finger and hand movements must be learned for whatever type of keying device is used. These correct motions must be practiced regularly to assure proper radio code sending.

Historically, the first sending device was the *hand key*, or *straight key*. The second was the *sideswiper*, *cootie key*, or *double speed key* (meaning a straight key which has two sets of contacts and sends code faster). The third was the *semiautomatic key*, or *bug*. The fourth was the electronically aided *electronic keyer*, often referred to as simply a *keyer*, or improperly as a *paddle* since bugs and cootie keys also have paddles. Keyers are somewhat similar to a bug in operation.

There is also the digital (binary/ASCII) keyboard, or *KB*, used in conjunction with some form of a computer/software system, which is not a key. A KB requires no code or keying ability to make it send CW. Its correlative, a computer with software that will decode received Morse-letter tones, also requires no code operating ability to receive perfectly generated CW letters.

The first three, purely mechanical telegraph keying devices, have been used since the mid-1800s to send "landline" railroad messages, telegrams, and stock exchange information using the American Morse code. Later they were used to send International Morse code for amateur-to-amateur, ship-to-ship, ship-to-shore, and point-to-point communications. How messages were handled is another story. This discussion is about learning to send code properly with a hand key, a bug, a cootie, and a basic keyer.

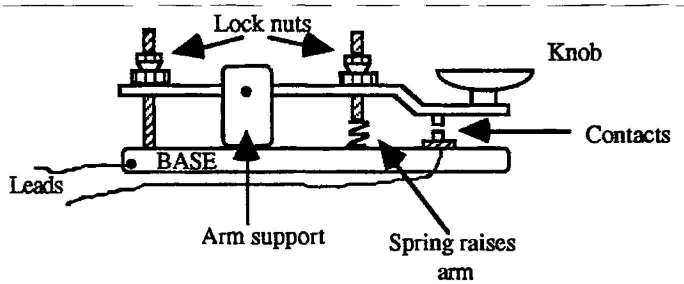

Fig. 1. Essentials of a straight or hand key, side view.

Begin with the basics

Let's start with the oldest and the simplest device, the hand key, which is supposed to be used on Hand-Key Night. **Fig. 1** shows this device in its simplest form. Such a key consists of a metal base, a metal up/down rocking arm, a spring to push the arm upward, and an adjustable stop at the back of the arm to limit how high the front of the arm will rise. It has some kind of an insulating-material knob

on the front of the arm. Most of the metal parts are electrically connected together and are connected to ground potential in radio circuits. Connected to and below the forward part of the arm is a downward-projecting upper contact. Directly below this, spaced perhaps 1/16 to 3/32 of an inch (1.5 to 2 mm), is a lower contact, insulated electrically from the rest of the key. When the knob is pressed downward against the spring's tension, it forces the upper contact to meet the lower, thereby "keying" (turning on) any circuit to which the contacts are connected.

If the knob of a hand key is pushed down only long enough to make a very short-duration contact it results in a "dot" (or short "dit" sound) being sent. If the knob is pushed down and held three times as long, it results in a "dash" (or longer "dah" sound) being sent. (This reasonably accurate 3:1 dash:dot contact ratio is the *first* challenge of sending good code letters.)

I recommend the following methods of operating keys and paddles. They are the result of five years of shipboard radio operating, four years of police radio CW, 26 years teaching International Morse code courses, and 65 years of operating on the ham bands.

One old-fashioned hand key knob has a small vertical bakelite bulb on top of a 2-inch round insulating-material bottom plate. The thumb, first and second fingers grasp the bulb. The dots and dashes are made by pumping the hand down and up (very tiring).

Modern American key knobs are usually round, flat-topped and about one inch in diameter. The method described here is for sending with the more modern key knob. In 1937, my ship, the *SS President Hoover*, was bombed by the Chinese while anchored in the Yangtze River. After sending an *SOS*, I sat and transmitted passengers' messages to the United States for five unbroken hours using such a hand key. Because the path from the *Hoover* to San Francisco (KDMW to KTK) was long, and conditions were poor on 36 meters, bug sending was out. Could you send without stopping for five hours using your present method of operating a hand key?

Here is the way to hold the knob to assure making constant-speed dots, each separated from the next by a space-time equal to the dot contact time, one of the

challenges of good sending: The tip of the first finger should rest on the flat-top knob at about a 12 o'clock position as seen by the operator. The thumb rests against the under part of the knob at about a six o'clock position. It may seem that the knob is being *grasped* by the thumb and first finger. Actually, the touching of both the thumb and the finger is very light. The thumb's only job is to prevent the first finger from wandering off its proper position on the top of the knob. The hand should be relaxed, but held parallel to the desktop, with the palm about two and a half inches above the desktop, the wrist about an inch above it. The arm muscle near the elbow rests on the desk. (A square piece of thin carpet, or other thin padding, under this muscle makes sending a lot more comfortable.)

The other three fingers? They are allowed to hang out in the air to the right of the knob (assuming that the operator is right-handed, although lefties send just as well).

The three fingers in the air have a very important job to do. As the hand is pushed downward from the wrist and is then pushed back up by the spring, the three fingers move down and up, along with the first finger on the knob. These fingers act as an up/down pendulum when sending dots, effectively setting the proper dot-space-dot keying. Dots made this way will produce a code speed of perhaps 15 words per minute (wpm) without any difficulty.

It *appears* that the first finger, or maybe the second, is doing the downward pushing, but actually it is the whole hand. In proper keying, when the key contacts close, your wrist should move upward slightly as the closing of the key contacts stops the downward movement of the hand, raising the wrist. Make *sure* your wrist does this. It is important! If your wrist goes down when your fingers go down you are not relaxed and you are making work out of what should be fun. You are sending with your whole forearm and not just with your hand and fingers. If you send several dots in a row your wrist should rise perhaps a half inch farther above the desktop.

To send faster than about 18 wpm, put both first and second fingers on the knob top. Now only two fingers are acting as a pendulum, allowing a faster up-and-down motion, and faster dots.

How tight should the key's spring be? This is a purely personal decision. Adjust it so that the key's movement feels neither too stiff nor too limp. The contact gap is also a personal preference setting. Try a gap of 1/16 to 3/32 inch (the thickness of three or four QSL cards?). Don't make it too small—you want a good up/down movement of your hand, not a nervous tremor.

(Practice the following: Using your key and a code oscillator or buzzer, send a series of about 100 dots a few times until you get a feeling for the proper pendulum action of your three outer fingers. Keep your hand parallel to the tabletop at all times.)

How about dashes? There's nothing automatic about them; dashes depend entirely on your sense of timing. The pendulum motion of the fingers may help to make dots but not dashes. The wrist should move upward slightly with every dash. Be careful—there is always a tendency to make dashes too short. Concentrate on making your dashes a little longer than you think they should be. With practice the dashes will shorten to a more correct length. If you have a transmitter and an oscilloscope that can show your RF output, connect a dummy antenna to the transmitter and watch the scope. If the horizontal sweep is adjusted to the correct speed you will be able to see the relative lengths of your dashes and spaces. The space between dashes should be one-third the length of a dash. And this should also be equal to both the length of a dot and the space between dots or dashes.

(Practice the following: Make a long series of dashes, trying to make the dashes all the same length and a little more than three times the length of the spaces between them. Yes, it's a challenge.)

One important point: Do not allow your finger to rise off the surface of the knob while sending. You should never be *tapping* the key. Push the knob down and let the spring return your finger upward without your finger losing contact with the knob top.

A good preliminary practice for making letters and numbers is to practice making a string of perhaps 50 dahdidahs—then a string of 50 didahdits—then 50 didahdahdits—then 50 dahdididahs—then 50 dididahdahdidits—and so on, until you are making strings that include five dots and then strings with five dashes in them.

Normally a hand key can be used for speeds up to about 18 wpm (to perhaps 23 wpm with two fingers on the knob.) If you want to go faster than about 20 wpm with purely mechanical keys, you might use the old-time sideswiper, cootie, or double speed key, shown in **Fig. 2**. It consists of a horizontally movable spring-steel arm that returns the arm to a central resting position when not pushed to either side. The steel spring is anchored at its far end to a post on the metal base that is normally at ground potential. The length of the arm-spring determines the stiffness of the side-to-side, or lateral, movement. A bakelite paddle, about an inch and a half long and three-quarters of an inch high, is attached to the arm's near end. To both right and left of the arm are adjustable screw contacts that are insulated from the base. The contacts are adjusted so that the arm must move about 1/16 to 3/32 of an inch from its resting position to strike either the right or the left contact. A quick push to the right will produce a dot. Hold it a little and the result is a dash. The same is true pushing the paddle over to the left contact. (It is actually a double horizontally-operated hand key, using both finger and thumb to make dots and dashes.)

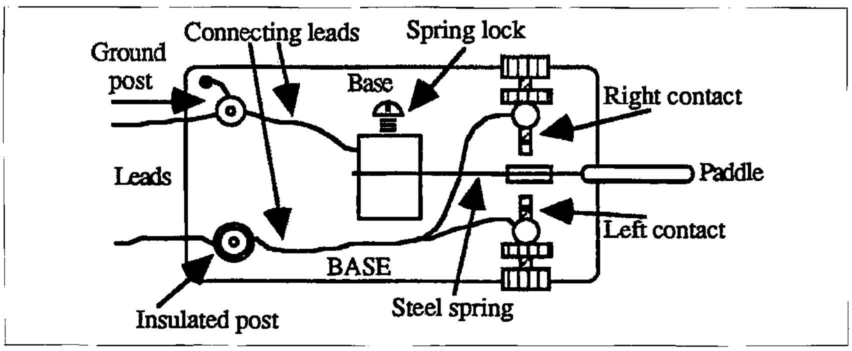

Fig. 2. Essentials of a sideswiper, double speed, or cootie key, top view. (If the right contact post is disconnected from the left, this could be the paddle of a simple electronic keyer.)

With a cootie key, if you move your finger and thumb back and forth rapidly several times you produce a series of dots. If you hold the contacts longer, you produce a series of dashes. A quick contact to the left followed by a longer contact to the right produces an "A." Similarly, a quick contact to the right followed by a longer contact to the left also produces an "A." (It takes a lot of practice to make these monsters put out good Morse code!) You have to be able to send both dots and dashes with both thumb and first finger. (Should a cootie key qualify for Hand-Key Night?) To learn to send with a cootie use the same didah practice suggestions above.

The cootie key represents the greatest challenge of any of the mechanical keys. Sideswipers were used in early RR and radio days because they were cheap and easy to construct. They are both easier to operate and will send faster than a hand key does, but relatively few operators use cootie keys today. You can usually recognize cootie operators by the "swing" (slight variations of dot and dash lengths) that becomes unique to each operator. Swing gives a special character to sending, setting the operator apart from the machine-like perfectly-spaced sending of electronically aided keyers and keyboards. (Unfortunately, commercially made sideswipers are no longer available but they're easy to put together from parts out of most junk boxes.)

The best hand position for the sideswiper and other side-to-side keys is to rest the right edge of the hand and the first knuckle of the little finger on the tabletop, rotating the upper part of the hand as well as pushing the thumb and first finger from side to side to make the dots and dashes. (An anchored hand position was a necessity for operators aboard rolling and pitching ships!) Don't be afraid to hit the paddle reasonably hard. This makes good solid letters.

The cootie is a good mobile CW key. A sideswiper can be used for code speeds in excess of 23 wpm without much difficulty.

Unlike using a hand key, neither the first finger nor the thumb should rest with any significant pressure on any side-to-side operated paddles, but they must never be far from it. When the thumb is pushing, the finger will be off the paddle, and vice versa. If paddle-type keys are not anchored, they will move when the paddle is pushed. To prevent this, coat the feet of such keys with rubber cement to secure them to the tabletop. Cemented down, they will take quite a beating without coming loose, and rubber cement is easily removable, leaving no residue.

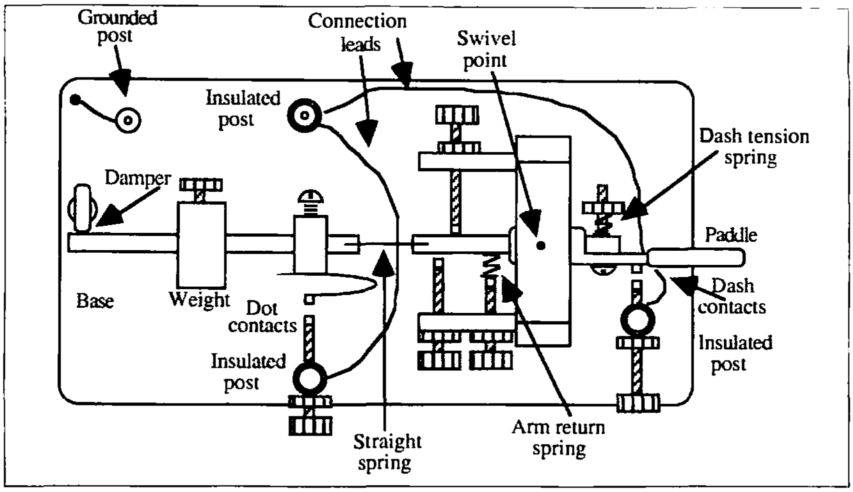

Fig. 3. Essentials of a semiautomatic key, or bug, top view.

The easiest mechanical key to use for speeds up to 40 wpm by good operators is the semiautomatic key, or bug, shown in **Fig. 3**. (It is shown with a simple, single paddle, although more complex paddles are also used.) The bug is a little like a cootie key. However, a bug has a straight spring at the end of its first horizontal-moving arm, which in turn is attached to a second, weight-carrying rod. This last rod can be made to vibrate side to side in pendulum fashion. Each time its U-shaped dot-contact spring hits the dot contact on the insulated post at the left, its vibration makes dots as long as the paddle is held to the right by the thumb. A quick push produces one dot; a slightly longer push produces two dots—a still longer push produces three dots, and so on.

Pushing the bug paddle to the left with the first finger connects the arm to a contact on a second insulated post. This sideways finger push makes dashes essentially the same as a downward-pushed knob makes dashes with the hand key. (When bug operators want to send code slowly they may use the dash paddle as a side-operated hand key.) The bug only makes dots automatically—it's up to the operator to make the dashes properly, in both number and length. The contacts on the dot and the dash posts are connected together electrically and are brought out at the insulated output binding post. The other output binding post is connected to the metal base. As with the cootie key, bugs should be whacked fairly hard to make sure that good solid dots and dash contacts are made.

Bug adjustments are more complex than those of hand and cootie keys:

•1. Whenever the paddle is released, the arm-stop screw at mid-right must be set to just stop the swing of the vibrating arm against the damper mounted at the far back edge of the bug. With the damping position fixed, the locknut on the arm-stop screw is tightened so the adjustment cannot change.

•2. Adjust the dash paddle swing at front left for a spacing of 1/16 to 3/32 of an inch and tighten the locknut.

•3. The dot-arm stop screw at mid-left is set to about 1/16-inch spacing and its locknut is tightened.

•4. The mid-left dot-arm spiral spring is tightened or loosened to a comfortable paddle feel.

•5. Move the weight (or weights) on the vibrating arm to the far end of the arm and tighten. This produces the slowest pendulum movement and therefore the lowest speed dots.

•6. Connect the bug across an analog ohmmeter. Push your thumb solidly against the paddle and watch the

ohmmeter indicator needle. Adjust the U-shaped spring's dot contacts until the needle vibrates at mid-scale, indicating the dot and space times are equal. Theoretically, this is the correct setting, but slightly longer dots than spaces are easier for distant stations to read. Therefore, adjust the dot contact so the meter needle vibrates at a point a little to the right of vertical or mid-scale. (When properly adjusted, the bug should make about 10 good sounding dots before it goes into a solid contact.) The dot contact can also be set by watching a scope while the transmitter is keyed into a dummy load.

With bugs, the tendency is to set the dots at too rapid a rate. Listen to your fastest *comfortable* hand-key dot speed, and adjust the bug dots to just a little faster than that. When you have perfected your bug sending at about 18 wpm (when you can send out of a book for one minute at 18 wpm without making a single mistake), then you can increase the dot speed for faster sending. Practice operating a bug using the same didahdidah suggestions made above for the hand key.

Remember a good old Code Sending Law: "It is unlikely that you will send well at speeds faster than you can receive well." Don't try to impress other operators by using high-speed dots—you can't kid them for long about your CW ability. On the other hand, if you can obviously receive and send faster than the other operator, slow down to a speed he or she can handle or you'll be wasting your time sending information not being copied. Remember, many slower operators can produce interesting, worthwhile QSOs.

A good operator can set his bug dots for about 30 wpm and never change them. If the receiving operator can only receive 18 wpm, the bug operator can put greater space between letters and words so that the average speed is only 18 wpm. This provides good practice for the other operator to copy more rapidly made letters. If the sending operator never has to change the speed, more error-free sending is possible.

Bugs may generate dots automatically, but it is still up to the operator to make the dashes three times the length of the dots. A newer post-WWII development is the fully automatic electronic keyer. Through the operation of its internal electronic circuits, when the thumb is pushed against the bug-like paddle, a continuous string of perfect dots is produced. Pushing the first finger against the paddle makes a continuous string of perfectly made dashes exactly three times the length of the dots.

Although dots and dashes can be made more perfectly with keyers, inter-letter and inter-word spacings are still important for readability. Using a dot time as the unit of measurement, inter-letter spacing should be three units long, inter-word spacing five units long, and inter-sentence spacing seven units. There is still a challenge to send good Morse code even with keyers.

If you have a keyer and would like to try operating it as a sideswiper, many keyer paddle assemblies can be clip-lead connected so that they can make a hand-key type contact when pushed either to right or left. The paddle can then be plugged into the hand-key jack and used as a cootie key (if your keyer is built into your transmitter, or is a self-contained operating unit, this will probably not be possible).

During a QSO, if you have to stop to think while sending, try to do it between words—don't do it between dots and dashes in letters.

Never break up a letter by leaving excessive space between dots and dashes in it somewhere. If you happen to do this, make the error sign (eight dots) and go back and resend the whole word in which you made the error. Try to make the dots/dashes of all letters together to form one tied-together sound, leaving a noticeably longer space between one letter and the next. Similarly, each word should be an unbroken unit of sound.

Use abbreviations sparingly—rarely will they save much time. More likely, the confusion developed by your not sending complete words will puzzle the other operator. When a letter in a word is interfered with by static, it is far easier to guess what the missed letter of a spelled-out word might be.

To make *perfect* dots, dashes, letters and spaces there is the computer keyboard program. When you type "CQ CQ" you transmit a perfect "CQ CQ" with perfect inter-letter spacing of three dots, and when the space bar is struck you get a perfect five-dot spacing if you are typing properly. To become a good keyboard operator you should probably attend a secretarial school to learn touch typing so that you can keep ahead of the speed you choose to send in real time on the air. If you can't type properly, if you have to hunt and peck, you will leave many spaces in words where spaces don't belong. High speed Morse code in which inter-letter and inter-word spacing is incorrect, or words are misspelled, is very discouraging to good receiving operators. Keyboards are great—if you know how to use them properly, but they don't provide much challenge.

Because keyboards do provide perfect sending of plain language material typed into their memories or buffers, they are used to provide perfect code speed practice to over 100 wpm! Without a source of perfect high speed transmissions there was no such practice available, but today, high speed copying ability can be checked easily by having an amateur listen for a few minutes to a high-speed plain-language CW transmission, and then summarize what was transmitted. High speeds around 100 wpm are too fast for ordinary people to copy onto paper. For high-speed communicating, CW keyboards only substitute the Morse code for the Baudot code of radioteletype, AMTOR, or the ASCII code, but the AFSK used with RTTY, etc. is considerably superior to electronic CW signaling if there is external noise present.

With the proper software program and electronic equipment coupled to a computer it is possible to display received Morse code words and sentences on a monitor screen (such programs will copy Morse code poorly if it is not sent perfectly).

The old-time American Morse code that used to be heard on the ham bands at times used different spacings in some of its characters and different length dashes. These could be made with hand keys, bugs and sideswipers, but not by keyers or by keyboards using the usual computer CW software. Too bad. It has caused the demise of that early-day, historical telegraph code.

If you like challenges, see if you can learn to send Morse code well with all three non-electronic keys! Let's all help keep ham radio's original means of communicating on the air—and try to interest *others* in participating more in the fun of good radio code operating. See you on Hand-Key Night this December 31st!

Continued from page 39

confiscate property. (4) The "war on drugs" has been a very expensive war and the government has lost it. This has been an enormous government fiasco. Get the government out of this mess and let the capitalist marketplace take over. (5) Get the government out of supporting prices. Let the market control prices and stop subsidies for tobacco, farmers, sugar, power, and so on. (6) The most expensive war in the history of our country has been the "war on poverty." The government, both state and federal, should get completely out of this failed social engineering project and let the market handle it. A number of people in government seem not to have noticed that socialism has failed in every country where it has been tried. They should be forced to visit some countries where it has been implemented, such as Russia, Yugoslavia, Sweden, China, Sudan, etc. I have. (7) Socialism has failed us in our school system. The law forcing kids to go to school is tantamount to slavery. With government-run schools costing two and three times as much to run as private schools, it is time for the government to get out of messing up the education business and let competitive for-profit forces provide this service. Our country had a much higher literacy rate before public schools were forced on us. (8) It is federal and state regulations which have made such an incredible mess of our so-called health care system, making it one of the most expensive in the world, yet providing us with third-world grade health care. Get the government out of this social engineering and let the market control our medical industry. (9) With lobbyists in every state capital and Washington, I would like to see an enforced law prohibiting any representative of the people from publicly discussing or voting on any matter in which they have a pecuniary (conflict) interest. Thus, if they accept money or favors from any person or group, they would be prohibited from being a paid agent of that person or group toward initiating or changing the laws possibly affecting that person or group. (10) Illegal immigration is against the law. Either change the laws or enforce them. Until the government social engineering projects providing free food, housing, money, education, and health care for illegal immigrants are ended our country will continue to be a powerful magnet for illegal immigrants, with the rest of us paying the bill or being put in prison for non-payment of ever-escalating taxes. (11) There's more, like our expensive postal monopoly, but that will give you an idea of the platform I would be delighted to support with my money, just as I believed I was supporting these concepts when I put my life on the line in WWII.

Scientific Evidence

Do you personally have to see something to believe it? Supposing the same event is reported by a number of people who have had no way to get together to concoct the story? Scientists have a problem believing in anything they can't reproduce on demand with 100% reliability, yet there is a wide variety of things going on which don't fit in with those restrictions. And, of course, if we get into religion or politics, we run into many areas of strongly-held beliefs that have no scientific support.

While I've always had an interest in the occult, UFOs, and other anomalies, I've been annoyed by the closed-mindedness of many people who reject the experiences of others. When something unusual happens, my instinct is to investigate it and try to understand what's going on, not to make every effort to reject or ignore it.

Scientists tend to sweep the unexplainable under the rug as "anomalies." For them that's enough of an explanation, and never mind trying to understand the anomaly or reproduce it. Doctors have the same mind-set, sweeping aside sudden cures for fatal illnesses as "spontaneous" cures. Thus, instead of trying to find out what in the heck brought about the "spontaneous" cure so it could be used to help others, they close their mental doors.

For thousands of years people have been reporting near-death experiences (NDEs). There's a magnificent book by Dr. Crookall, *The Supreme Adventure* (1961), which examines hundreds of NDE reports and shows how remarkably consistent they are. He then takes the next step and examines hundreds of reports from the "next world" as received through mediums. These, too, are consistent with the NDE reports. It's almost enough to make a person think.

I've read three recent books you might want to look for. There's Dannion Brinkley's *Saved By The Light* (1995; 204p), where he was struck by lightning and had quite an NDE. It's worth the $6. Unlike most other visitors to "heaven," Dannion claims to have been given some glimpses into the future. If you've been keeping up with the latest in technology you'll find his piece on the coming development of DNA-type computer systems most prescient for a 1975 NDE experience.

Then there's Mally Cox-Chapman's *The Case For Heaven* (Putnam 1995; 203p; $30). She goes into detail about her own experience, and then tells the stories of dozens of more people she's interviewed who've had similar experiences. Having gradually become an old man, and thus perhaps a little more concerned with death, these "light" books are of increasing interest to me.

There's Betty Eadie's *Embraced By The Light* (1994; $6; 145p). You should be able to whip through it in less than an hour. She puts more of a religious interpretation on heaven than most others who've been through the experience, but her story is quite similar to all the others in most respects.

Another NDE resource is Cherie Sutherland's *Reborn In The Light* (1995; $6; 303p). Like the others, she reports on a number of people she's interviewed. Their stories are remarkably similar. There is the pattern after the NDE of no longer fearing death, but

Smiles are virtually guaranteed when hospitalized kids talk with St. Nick.

April Moell WA6OPS and
Joe Moell KØOV
P.O. Box 2508
Fullerton CA 92837

We discovered the joys of ham radio Santa visits 20 years ago when April was a department head at a large hospital. One December day, she heard that a group from a prominent Los Angeles area ham club would be coming that evening to let the Pediatric unit children talk to Santa. She phoned the club's contact person and volunteered to serve as a hospital liaison.

Only one ham from that club (Jack Lemaster WB6ECB) showed up. Rather than disappoint the kids, the three of us put Santa on the air. That hooked us; we've done it every year since. We have lots of help from the hospitals and from members of the Hospital Disaster Support Communications System (HDSCS), an Amateur Radio Emergency Service unit here in Orange County. Even though Jack has moved out of the area, he occasionally comes back just for this activity.

Photo A. *"Santa knows me!" This moment of surprise is the best part of every QSO with St. Nick. April Moell WA6OPS holds the mike.*

Personalize it

Everyone loves to be called by name. What could be a greater thrill to a youngster at Christmas time than to have Santa himself recognize you? That's exactly what happens when HDSCS visits Children's Hospital in December (**Photo A**). After the roving operator is introduced to a patient, the radio call is made: "Calling the North Pole! This is WA6OPS in Orange County, California. Santa, we're in room 217 of Children's Hospital by Bed 2. Do you know the little girl here?"

For a few seconds, her receiver emits the sound of reindeer, sleigh bells, the cold north wind and then, "Ho, Ho, Ho! Merry Christmas, Jennifer! How is Chips, your new little puppy?"

Jennifer is an instant believer. Santa has established his credentials in a big way, thanks to earlier sleuthing by hospital elves. Over the past week the nurses and therapists quietly collected information about every patient to be visited. It doesn't take a lot—just enough to assure the youngster that Santa is for real.

Even the most skeptical kids are hooked by a well-prepared Santa. In one four-bed room, patient #1, an eight-year-old boy, feigned great disinterest as we came in, so we talked first to the others. He perked up noticeably as Santa greeted patient #2 with his name and some personal information. As Santa next gave a similar hello to patient #3, patient #1 bounced up and down in his bed and shouted to patient #4, "That's the Man! That's the REAL one!" He could hardly wait for his own turn.

Of course, information gathering must be done inconspicuously by the staff. Usually there is useful data in the medical chart and their own notes. Santa can make use of the child's name, age, nickname, grade in school, family members, pets, a favorite toy or food, special interests, etc. Only a few of these items are necessary for any particular child.

"Patient #1 bounced up and down in his bed and shouted, 'That's the Man! That's the REAL one!'"

If it would be helpful to have words of encouragement from Santa and Mrs. Claus such as, "Work hard in your physical therapy," let Santa know in advance. Of course, Santa should never promise to bring specific gifts, but if it is known that a certain item is planned for a child, it might be appropriate for Santa to comment that "The elves are working on it in the workshop." Elves should be sure to let Santa know of any sensitive matters. For instance, you don't want him to mention Dad when a Dad doesn't exist.

Most of our elf work is done before the hams arrive, but it's also good for Santa to have last-minute intelligence to fill in the gaps. A "spy elf" goes along with our ham entourage from room to room. She quietly observes what the kids are wearing, what decorations are in the room, what they are doing, and what family members are

present. Then she goes outside the room and surreptitiously clues another elf at Santa's communications center,, who relays the information to Santa (**Photo B**).

The staff at Children's Hospital loves elf work and looks forward to the hams' coming. Sometimes they even sneak in a little "behavior modification." When Santa greeted one little boy by name and asked if he was still sucking his thumb, the thumb shot out of his mouth and stayed out for the remainder of the visit.

Photo B. *In a secret location within the hospital, Santa's helpers handle the North Pole linking and elf work. Left to right are Tom Gaccione WB2LRH, an unnamed hospital volunteer, "Woody" Woodward KJ6LE and Ken Simpson N6IDE.*

Gifts for the kids

We have heard of groups that give out candy canes after each Santa QSO, but they risk protests from the nursing staff. Sweets may violate dietary restrictions and can be an infection hazard for patients in isolation. Small toys or stuffed animals are better. Of course for infants and toddlers these items must be "kid-proof," with no parts that can be pulled off and ingested.

For the past 12 years, we have given out two-inch round buttons that read, "I talked to Santa on Amateur Radio." Everyone loves them, including parents and nurses, who frequently ask if they can have one, too. (Sure, if they talk to Santa!)

These buttons are great publicity for our hobby. The patient and his entire family are reminded that amateur radio is the service that brought them St. Nick. In the early years, we heard ourselves referred to as "the CB group that talks to Santa Claus," despite our educational efforts. Since we started passing out the buttons, the confusion has stopped and they have become collectors' items.

Such buttons are easy to obtain and are popular with youth sports leagues. Your club may have a member with a button-making machine; the cost of materials is not high. Another alternative would be an adhesive sticker, about the size of a name tag, with the same words.

A new name

Old-timers say that this activity has been going on in Southern California for 40 years, traditionally called "Operation Santa Claus." Tradition is nice, but we stopped using that name long ago. It was causing confusion to hams and non-hams alike. At least one of the military services and several other organizations here have used this same name for their holiday charity efforts for many years. When we would mention our "Operation Santa Claus" activities, listeners immediately assumed we went around collecting toys.

Today we use a much more descriptive title: The "North Pole Network." In news releases, we call it the "North Pole Amateur Radio Network" for further clarity. If you like this name, we encourage your group to adopt it.

We nixed the boob tube

After our first year of Santa hospital QSOs, we got the bright idea of using 430 MHz ham television (ATV) to let the kids see Santa as they talked to him. The next year Santa transmitted on that band and we lugged a cart with a TV set, ATV receiver and yagi antenna from room to room. Multipath propagation of signals through the hospital corridors resulted in noisy ghosting video. The kids weren't impressed.

For the next several years, Santa was visible in each kid's room via the hospitals' closed-circuit TV systems. Video and audio quality was much better, but Santa had to be on camera for almost three hours as the radio operators went room to room. Besides being hard on Santa, who had to "mug" for the camera in between QSOs, it meant we could not covertly give Santa last-minute elf information, and we found ourselves putting on a full-blown TV production each year.

Nowadays, we use radio only. Santa likes it better, because he can concentrate on talking to the patients and not worry about his appearance. The kids are just as happy, because their imaginations can create a better Santa image than we could ever provide.

To ensure good radio coverage of each room, we put Santa in an out-of-the-way office within the hospital. The link is on an obscure simplex frequency, rather than a repeater. This has eliminated inadvertent and malicious interference, which could ruin the event and be an embarrassment to both hams and hospital staff.

We have discovered that 223 and 440 MHz are much better for Santa communications than 2 meters, for two reasons. First, UHF signals propagate much better than VHF within the halls and floors of hospitals. Second, computerized hospital equipment often radiates "birdies" that cause loss of receiver sensitivity at 144 MHz, but they are usually not present on higher bands.

Include all ages

Everyone wants to be nice to kids at Christmas. North Pole Network is just one of the many events at Children's Hospital of Orange County every December. There are carolers, clowns, firemen, and so on. But who brings holiday joy to older hospital patients?

Christmas time is an emotional roller coaster for a patient with a physical disability. The joy of the season can be offset by the miseries of infirmity and loneliness. You might not think that a talk with Santa on radio would mean a lot to a teenager, a middle-ager, or a senior citizen. After all, the patient is old enough to realize that Santa isn't really 3,800 miles to the north. But for many, this annual visit is a real uplift.

The patient is cheered by the friendliness and by the fact that a group of strangers thought enough of him or her to put on a special program. All the wonderful

memories of Christmases past are rekindled. As one elderly gentleman exclaimed into the mike, "Santy, it's good to talk to you again. You and I go 'way back!"

Getting in the door

If someone in your club is or knows an employee of your local hospital, have that person find out whom to contact to arrange for a North Pole Network visit. At large children's hospitals, ask for Recreation Therapy or Child Development staff to assist.

At most local community hospitals, you will have the best results by starting with the public relations department. These employees often arrange visits from local volunteer groups such as Christmas carolers and firefighters. Keep in mind that many facilities have only a few children in the Pediatrics unit. As Christmas approaches, most will be sent home if possible and only the sickest will remain hospitalized. Consider visiting both adults and children at these locations.

Hospitals with rehabilitation centers usually have Recreation Therapists who arrange special activities for patients. If there is no Recreational Therapy department, contact the Occupational Therapy department. Convalescent or skilled nursing facilities have an Activities Director or Recreation Leader. These people are always looking for activities for their patients and if you present North Pole Network appropriately, they will be delighted to plan for your coming.

"One elderly gentleman exclaimed, 'Santy, it's good to talk to you again. You and I go 'way back!'"

Most hospital staff have no or little familiarity with amateur radio. It is important to meet with staff beforehand to acquaint them with what you want to do. Show them this article and tell them about your previous North Pole Network experiences, if any. Demonstrate the equipment you plan to bring into the hospital.

Be prepared for some hesitancy. Most hospitals are concerned about interference with their medical equipment. Assure them that ham hand-helds are not like cell phones (usually banned in hospitals). Experience has shown that the potential for interference is very low. But if they do not want you to transmit from rooms with respiratory equipment or specialized monitors, comply with their requests without argument. Always use the lowest transmit power possible. Use a speaker-mike on your hand-held and sterilize it with alcohol as directed by the nurses when you visit patients in isolation rooms.

As North Pole Network veterans, we know what a wonderful feeling this program can give to hams, patients, and the hospital staff. We hope your club will join the fun this year.

April Moell WA6OPS is head of the Hospital Disaster Support Communications System (http://members.aol.com/emcom4hosp on the Web). Her E-mail address is emcom4hosp@aol.com. Joe Moell KØOV is *73*'s "Homing In" columnist. No, he doesn't play the part of Santa.

CARR'S CORNER

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041
E-mail: carrjj@aol.com

One of the nice things about ham operators is that they have a lot of technical interests, some of which are related to ham radio, and others which aren't so related. I've come across a series of products that will meet both classes: the Speake & Co. FGM-x series of magnetic sensors. These sensors are distributed in the United States by Fat Quarters Software [24774 Shoshonee Drive, Murrieta, CA 92562; 909-698-7950 (voice) and 909-698-7913 (FAX)].

There are several different sensors in the series, and these are designated models FGM-1, FGM-2 and FGM-3. **Photo A** shows the Speake FGM-3 magnetic field sensor. It is 60 mm long by 15 mm diameter (2.36" x 0.59"). One of the other sensors in the series is a bit smaller.

The FGM-3, which I have a sample of, is a three-lead device. A set of three wire leads provides connections to make the sensor operational: red +5 VDC; black 0 volts (ground); white output signal (TTL compatible).

The output signal is a frequency that is proportional to the applied magnetic field. The magnetic detection rating of the device is ±0.5 Oersted (±50 µTesla). This range is said to cover the range of the Earth's magnetic field.

Multiple FGM-x sensors can be used to provide such things as compass orientation, three-dimensional orientation measurement systems, and three-dimensional gimballed devices such as virtual reality helmet display devices. It can also be used to provide magnetometry (including Earth's field magnetometry), ferrous metal detectors, wreck finders (diving enthusiasts take note!), conveyer belt sensors or counters, and a host of other applications where a small change in magnetic field is the important transduction event.

One way that hams can use the FGM-x series of sensors is as a magnetometer used to correlate fluctuations in the Earth's magnetic field to propagation changes. Some hams use an array of instruments to study radio propagation. I've seen (or heard of) the use of Geiger counters, 15 to 33 kHz VLF receivers, HF receivers permanently tuned to a station like WWV, and a species of home-brew magnetometer called the "jam jar magnetometer." The Speake/Fat Quarters FGM-x series of sensors can be used to replace the "jam jar." It might be interesting to see what can be learned by having a radiation detector, VLF radio detector, WWV receiver and FGM-x magnetometer collecting data in parallel. With the modern, low-cost data acquisition capabilities of computers, it should be easy to collect such data round-the-clock.

Also, I've noted that the 8088-based "XT-class" MS-DOS computers, which don't run Windows©, can be used for such monitoring with the simple addition of one of those multichannel A/D converters that operate from the parallel printer port of the computer. Those XT-class computers can be obtained in a price range from free to about $50, with hard drives in the 20 mbyte to 100 mbyte range. With such a low cost data acquisition platform, one need not worry about a distant lightning burst generating a line transient that snuffs out the computer. If it does, then so what? Buy another $50 wonder machine and go again.

The FGM-series device output is a +5 volt (TTL) pulse whose period is directly proportional to the applied magnetic field strength. This relationship makes the frequency of the output signal directly proportional to the magnetic field strength. The period varies typically from 8.5 µS to 25 µS, or a frequency of 120 kHz to 50 kHz. For the FGM-3 the linearity is about 5.5 percent over the ±0.5 Oersted range. Speake and Fat Quarters literature claims that these sensors are superior to Hall effect devices because they have a much better temperature coefficient.

In addition to the FGM-3, there are also the FGM-1 and FGM-2 sensors (which should be available soon in the USA). The FGM-1 is a smaller version of the FGM-3, with a range of ±0.7 Oersted (±70 µTesla). It is basically the three-terminal FGM-3 device, but in smaller form and with a fourth lead wire to permit feedback for linearity improvement and zeroing of the output frequency under external control.

The FGM-2 is an orthogonal sensor that has two FGM-1 devices on a circular platform at right angles to one another. This orthogonal arrangement permits easier implementation of orientation measurement, compass and other applications. One possible application that intrigues me is as an antenna orientation sensor. Also, it occurs to me that the orthogonal sensor might be used to cancel out the effects of local magnetic sources other than the desired one, such as a guard antenna on an array might do.

The price of the FGM-3 is $36.50 as of this writing. There is also a high sensitivity, limited range device called the FGM-3h for $38.75. Shipping and handling is $2 for the first item, and $1 each for additional item in the same package. The price of the FGM-1 is $36.50, and FGM-2 is $54.75. Keep in mind that these are imported sensors, so the vagaries of the currency exchange rate could affect the actual price. If you order now, I suspect that the prices quoted in their literature (and reproduced above) are valid, but if you wait a while, until they have to restock, then you will risk an increase in price as the dollar and pound sterling move relative to each other.

Special IC devices for the FGM-3

Speake also offers a series of special purpose integrated circuits that interface the FGM-x series of sensors to other things. One that

Photo A. The Speake FGM-3 magnetic field sensor.

I've had some experience with is the SLC-006 device. It can be used with a DAC to produce an analog voltage output, as well as alone if you want an eight-bit binary digital output.

The other IC devices intended for use with FGM-series sensors are the SCL001 magnetic field nulling system and gaussmeter, the SCL007 high sensitivity gradiometer and magnetic anomaly detector, and the SCL002 vehicle detector. Fat Quarters has developed a printed circuit board for the SCL-006 device and can supply it in either kit form or built. Give 'em a try.

High school science teachers might want to keep the FGM-x series of sensors in mind for classroom demonstrations, and for their students' science fair projects.

Note: The applications literature for these devices is available from Fat Quarters Software (see address earlier). You will find that the circuits use the European method of specifying components. For example, a 4.7 µF capacitor is listed as "4µ7"; a 0.47 µF is "µ47"; a 4.7k ohm resistor as "4k7"; and so forth. They also use the units nanofarads (nF), which may be unfamiliar to North American readers. One nanofarad is 10^{-3} microfarads, so 1 nF = 0.001 µF = 1,000 pF. When you see a "1N5" capacitor listed, it is 1.5 nF or 0.0015 µF.

Write to Fat Quarters Software for their catalog sheets and tell Erich Kearn "Hi" from me.

HOMING IN

Radio Direction Finding

Joe Moell P.E. KOOV
PO Box 2508
Fullerton, CA 92837

Globetrotting Foxhunters

Enhancing international goodwill is one of the main reasons ham radio exists. The words are right there in the Basis and Purpose paragraph of the FCC rules governing our service. The many good deeds of hams in the past have helped protect our bands during international spectrum allocation conferences.

Most hams think international goodwill only refers to DXing, contesting, and emergency relief communications on the bands below 30 MHz. But you don't have to upgrade to General Class or higher to be an ambassador for ham radio. Even if you're still studying for your license, you can get involved in radiosports and compete in a worldwide arena.

Regular "Homing In" readers know that radio-orienteering is a growing sport for all ages. At international style "foxhunts," a number of low-power transmitters are hidden in a large wooded area. Using simple radio direction finding (RDF) equipment, along with a map and compass, competitors attempt to be the first to visit all of the "fox" transmitters and get to the finish line.

For all the basics of radio-orienteering, which is often abbreviated ARDF, read "Homing In" for December 1995 and January 1996. There you will learn about efforts to hold international-rules foxhunts here in the USA. This month, I'll cover championship foxhunting worldwide and tell you about stateside hams who are going abroad to get involved in it.

Photo A. Fifteen-year-old Steve Ewing KB7MFO went on his first foxhunt in Khabarovsk. Though inexperienced, he was speedy and ended up being the second-best American finisher. (Photo by WA7VTD.)

Portland pioneers

Seven years ago, a group from Portland made ham radio history by being the first from our country to participate in a multi-nation foxhunt. The event was held in Khabarovsk, a city in Asiatic Russia, under the auspices of the Friendship Amateur Radio Society (FARS). A part of the International Sister Cities program, FARS has forged a strong link between hams in Portland, Oregon; Tokyo, Japan; Victoria, British Columbia; and Khabarovsk. Every two years since, FARS has held the Friendship Radiosport Games, an international get-together featuring a variety of contests, including a 2 meter foxhunt.

The most recent Games were held last year in Khabarovsk. Kevin Hunt WA7VTD was one of USA's Team Captains. "This was the best trip ever," he told me. "They pulled out all the stops. The games took only four days but we were there for two weeks. We took a side trip to Vladivostok on the Transylvania railroad, went fishing on islands on the Amur river, had parties, dined on caviar, fresh fish and delectable home-grown vegetables. The government underwrote a large portion of the costs of hosting the games. We were welcomed by the Vice-Governor of the Territory."

Others from the Portland area who traveled to Russia for the 1995 Games were Rene Berblinger KX7Z, Dick Fredrickson WAØDIM, Dan Early WA6IRO, Steve Ewing KB7MFO, Dale Mosby N7PEX, and Mary Jo Mosby KB7NJE.

ARDF is a regular ham radio activity in many parts of Russia and is the most popular use of the 2 meter band there. One member of the Russian team teaches foxhunting in his country's schools. Therefore, it was no surprise that the foxhunt course was difficult and the Russians were fierce competitors. Besides the Russians, Kevin and his team were up against two teams of Canadians, who have been practicing hard to improve their foxhunting skills since FRG-93 in Victoria.

Photo B. For the official Region III Championships photo (Queensland, Australia), the competitors stood behind their societies' markers. At left is Kevin Kelly N6QAB representing the USA. (Photo by Susan Kelly.)

According to Canadian team member Perry Creighton VE7WWP, "The exact rules for the Khabarovsk hunt were not announced until the last moment. The competitors were trying to figure them out as they stood on the starting line." As it turned out, rules were quite similar to International Amateur Radio Union (IARU) standards. The minimum age for the Old-Timer category was 42 instead of 40. Instead of a distinctive punch at each fox, there was a concealed official who would mark competitors' cards with a secret initial.

VE7WWP continues, "The foxes were well hidden. The orange markers (prisms) were supposed to be visible within five meters, but in one spot they had the fox buried under a pile of leaves. The official was watching from a tree a ways away recording numbers. Some people spent a half hour looking for that particular fox, then gave up and carried on. That created a bit of consternation.

"I went right up to one strong signal location, walked around it for about 20 minutes and finally got disgusted." WA7VTD told me. "I ended up going overtime and getting disqualified. On the other hand, WAØDIM was cynical and decided that it simply had to be in a big pile of blackberry bushes. He got down on his hands and knees and suddenly he saw a pair of eyes. There was a Russian soldier in camouflage buried under the big pile of brush. Dick stuck his card in there and the guy just smiled and marked it."

The foxhunt site was a large section of thick forest near Camp Dubkii. Total course length was very long, about 10 kilometers, with five fox transmitters. "Athletes found it necessary to DF their way back to the continuously-running finish-line fox," Kevin says, "because tree density on the course rendered map navigation nearly impossible."

The difficult course and well-trained opponents resulted in a bad day for the red, white and blue. Anatoly Kozurov stunned everyone by finding all of his foxes and crossing the finish line in 50 minutes. He narrowly edged out second-place winner Alexander Turkin, who won eight other gold medals in the Games.

One shining star for the USA was 15-year-old Steve Ewing KB7MFO (**Photo A**). "It was amazing!" says WA7VTD. "At the last minute I explained to Steve how to use the Russian RDF gear. He had never done foxhunting or any kind of contesting, but he ended up the second best American foxhunter at the match."

Both Canadian teams did better than the USA teams. "We are very serious about foxhunting," Perry says. "We practice each week in Victoria. I believe we proved that we can run with the Russians in the woods. Our problem was not equipment, it was legs. None of us were under 42, some of us are hitting 60, and one of our guys is 75."

WA7VTD told of some unexpected events during the hunt: "Two contestants surprised amorous

couples in the deep woods. Russian competitor Oleg Stavitsky stumbled across the day-old corpse of a homicide victim. The militia and police graciously allowed the hunt to be completed prior to removing the body. A suspect was arrested the next day."

Many of the USA participants had been to Khabarovsk for the first Games in 1989. "Although prices of goods are more realistic and goods themselves are in greater abundance, the upheaval of the past five years has created many homeless people and organized crime is thriving," Kevin says. "Most Russians earn less than $100 per month and government support of medical care and education is being dismembered. Nonetheless, our enterprising ham colleagues continue to find ways to make ends meet. The hospitality shown to the visiting hams was nothing short of spectacular.

"We were hosted by the families for one week and then put up for one week at a hotel," VE7WWP adds. "It was very enjoyable. I wouldn't have missed it for the world and I have every intention of going back on another visit."

A championship Down Under

The route to a world championship gold medal in radio-orienteering is through the IARU. Member societies sponsor national championships and they collaborate to put on championships at the Region and World levels on a rotating basis.

There are three IARU Regions: I is Europe, Africa and former USSR countries; II is North and South America; III is the rest of Asia and the South Pacific. IARU Region II has no official ARDF activities, sad to say, but contestants from our continent are welcomed as "friendship" category competitors in all IARU sponsored radiosports events.

Avid transmitter tracker Kevin Kelly N6QAB of Lusby, Maryland, has family ties to Australia, so he planned his 1996 vacation there to coincide with the IARU Region III championship in Townsville, on the northeast coast of Queensland. Kevin and I exchanged E-mail with Region II IARU officials and obtained authorization for him to be the official representative of the ARRL (the USA's IARU member society) at the championships (**Photo B**). As a result, Kevin says, "I got the royal treatment."

China is the leading ARDF proponent in Asia. That country has been active in the sport for many years, holds many internal competitions and has excellent radio-athletes. Kevin says Region III Championships Chairman Wally Watkins VK4DO learned about ARDF when he was stationed in China. Since then, Wally has played an important role in bringing it to Australia. China was well represented at Townsville, as well as Korea, Japan, New Zealand, Australia, Poland, Kazakhstan (**Photo C**) and Bulgaria. Also present were observers from Thailand and Malaysia.

The Championships lasted for four days. The first day featured a practice run on the University grounds with just two foxes (**Photo D**). The second day was the 2 meter competition. Then there was a day of rest and ceremony, including a reception with the mayor, followed on day four by the 80 meter competition.

Each competitor provided his or her own RDF gear. There were wide variations among sets from different countries. "The Koreans had different colors of fluorescent paint on their antenna elements," Kevin says. "It looked like they were using some exotic archery gear."

Exact sites were not announced in advance. "For the 2 meter hunt we met in a parking lot," N6QAB reports. "Buses showed up and we had to get on them. Nobody was allowed to drive. The bus took 45 minutes to get to the start point, somewhere near Mt. Louisa. They had it all set up with a covered awning and special places for the gear of each country. Once you left the start you could not come back to it, period. You put all the stuff that you weren't going to take with you in a plastic bag and gave it to them. They carried all of it to the finish point.

"You didn't have to find the foxes in order," Kevin continues. "I came out of the starting corridor and there was one strong signal right in front. The next fox was on the same bearing line, so I figured I'd take two at once. As I went along, it becamc apparent that the rest of them would be on the return trip.

"I went over a hill, walked a while, scaled another hill, and finally just over the rise I saw a couple of referees. I became intent on watching them, thinking they were watching the fox. Bad assumption! I walked right by it and spent two full five-fox cycles

Photo C. *The Kazakhstan team came from the Higher Radio Engineering and Radio Sports School. At left is UN7JR, the foxhunting teacher. (Photo by N6QAB.)*

looking where I was probably within kicking distance. In heavy brush, that red flag doesn't mean squat unless you're right on top of it.

"At the next fox, the judges were hiding, but I saw a purple bag about a hundred yards away from me. I thought, 'That's not naturally occurring.' Sure enough, about 10 feet from that was the prism. As I went to it, they popped up from a crevice about 10 feet from me and waved.

"For the next transmitter, I had to go cross-country, away from the trails. All of a sudden there was a little shack with all kinds of stuff around it. Some guy was sitting out in his yard looking like a prospector. I could see where he had been doing some shooting. But there was no fox there.

"This was a lot longer course than any other foxhunt I had been on, even though I was taking the right route. A signal would be really strong and I kept thinking I was close and then there would be another hill to go over. I kept saying to myself, 'Hey, I'm in the Old-Timer category,' and I was liking it because I only had to find four of the five transmitters.

"I was being very careful not to go over the two-hour limit and disqualify, but I exerted so much that I started getting cramps in my legs. This never happened before. I had really good bearing on the fourth fox. I think it was on top of this really big hill, but I had only 20 minutes left so I gave up and headed for the finish line."

As **Table 1** shows, the Chinese were the big winners. Even though N6QAB didn't find all his foxes, he fared better than some contestants. "One of the New Zealand guys broke his ankle in three places," Kevin reported. "He was really laid out, but he still had his sense of humor. A Japanese hunter fell and hit his head. He came running through the finish line with a big red headband. After I made some comment about it, he took it off and there was blood all over."

There was plenty of non-radio fun at the Championships, too. Delegates visited the Billabong wildlife sanctuary, mountain biked and rode scooters on islands and beaches. "Almost every competitor was a licensed ham," Kevin says. "A lot of them didn't speak English, but English was the official language. The headmaster from Kazakhstan spoke excellent English. One fellow from Poland spoke Russian and interpreted a lot for me."

Future opportunities

The two Kevins and all the others who have taken part in multinational radio-orienteering competitions know that these events are unmatched for enhancing ham-to-ham international goodwill. There are plenty of upcoming opportunities for you to get involved in the sport. The next IARU World ARDF Championships are scheduled for Bavaria, Germany, in September 1997. If you are interested in attending as an observer or participant from North America, contact me and I'll try to help get your credentials.

FARS-Tokyo will host the next Friendship Games in 1997. The organizers will host 10 participants from USA and 10 from Canada; all others may participate unofficially. FARS chapters in USA and Canada are planning a North American Open Foxhunt to select members of the respective teams for the Tokyo meet. To find out more about this and other FARS activities, write to FARS, PO Box 13344, Portland OR 97213. FARS may also be reached via packet radio: KC7LRM@W7KYC.OR.USA.NOAM. Canadian foxhunters should contact FARS-Victoria via Perry Creighton VE7WWP, 4011 Hollyridge Place, Victoria BC Canada V8N 5Z8, or send E-mail to fars@bc.sympatico.ca.

I hope your club is planning its own international-rules foxhunts to promote the sport and give members a chance to practice and learn the skills. See the two-part "Homing In" series in the August and September 1996 issues for details on how to put on such events. Also check the "Homing In" web site (http://members.aol.com/homingin/) for more help, plus the latest news of upcoming ARDF events and links to ARDF sites in Europe and Asia. Let me know about meets in your area well in advance, so I can help spread the word. Send E-mail to Homingin@aol.com or postal mail to the address at the beginning of this article. 73

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

It's the December issue already, and probably the right time to turn most of our concentration toward warm indoor activities, at least here in the frozen Northland!

Net nite adventures!

From William Thim N1QVQ: "This idea may not be totally new, but bears repeating just in case some may not have heard of it... it concerns some operational suggestions for 'Emergency Practice Nets.'

"When the net control station feels that his or her net members are ready, try not starting the net on time and see what happens! You should have a back-up net control station. How long will it take your backup to jump in and assume control of the net? On a different occasion, prearrange with your backup to also not take over then see how long it takes for one of the participants to assume the reins. These 'readiness' tests may seem a bit deceitful at first, but they are good hallmarks of the net's ability to 'run itself,' as it well might have to during an actual emergency.

"We all get used to having things happen in a comfortable, familiar way, but that's not always to be expected in a true emergency situation, because an emergency—by its very definition—is itself unpredictable.

"Here's another test: Try telling all of the check-ins that your emergency battery power is failing, to please recheck-in again five minutes from now, and then see how many actually do. During actual emergencies, you may not have time to fully explain a situation and the net members will have to comprehend something unusual quickly, and follow your suggestions without any further guidance.

"Still another good test would be to tell everyone that they've just lost their normal antenna setup and to check in as soon as they can on their back-up antenna—however simple that might be. Perhaps some stations will have to relay for others who can't be heard by net control; how well is this handled?

"Finally, and this test applies to VHF/UHF repeater emergency nets, announce that the repeater will be turned off, simulating a loss of power at the repeater site. Again, stations will have to be ready to relay for each other and be able to copy weak and noisy signals from around the normal net area, proving that in actual emergencies copy may not always be 'armchair-clear' during times of distress. How well does this work?

"There are probably many more test-worthy scenarios that could be explored by inventive emergency net control ops and members alike, that will add realism and adventure to what might otherwise be routine net nights... while also providing a truer yardstick of how well your emergency net really is trained in its own emergency preparedness."

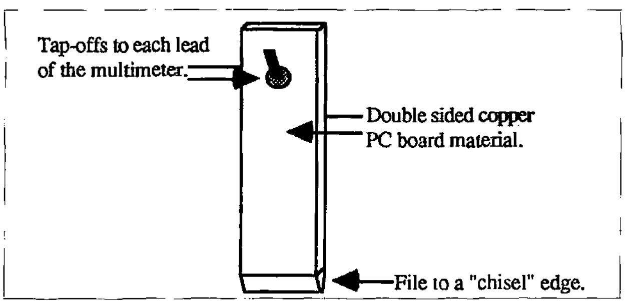

Fig. 1. K9KPM's "Battery Paddle." The paddle is made of double-sided circuit board material for inserting between two cells in a spring-loaded pack to measure the total current being drawn from the battery pack. See text for details.

Paddle your batteries

From Ken Guge K9KPM: "Have you ever wanted to measure the current drain from a particular piece of ham gear, or perhaps your daughter's portable tape player that's driving you close to the poverty level with AA batteries? I often thought that battery manufacturers ought to give these things away just to keep you in the high-volume battery-purchasing market. Well here's an easy way to put a milliammeter in series with those cells, without having to cut into the circuitry itself.

"Take a piece of scrap double-sided printed circuit board material (about 1/2" wide by 1-1/2" tall, and solder a short length of stiff wire on each side of the double-foil-sided board. These will be the 'quick' connection points for your VOM. Next, on the opposite end, file the 1/2" side down to a 'chisel shape' so that it will slip easily between two of the series connected cells in the spring-loaded holder (see **Fig. 1**). Now, when you insert this 'Battery Paddle' into the pack, you'll interrupt the current flow, but then hooking up your milliammeter will restore the flow and give you an accurate estimate of how much the little battery-eater is drawing.

"You can use this as a troubleshooting aid and know right away when you've cleared a high-current-drain problem or use it simply to check the battery drain for the sake of curiosity.

"If you make two of these paddles, you can insert one at each end of the series battery circuit, so that you can hook up a charger to the 'cell-side' of each paddle (being careful to observe the correct polarity), if you've decided to stop buying throwaway cells and use rechargeables instead.

"If you hook up a test power supply to the 'equipment-side' of each paddle (again, observing correct polarity) you can power the item from that external supply, instead of from the internal battery cells, for those times when it might receive extended use.

"I hope that this idea proves as useful to others as it has for me."

Moderator's note: Good tip, Ken. By the way, here are some typical milliamp-hour figures for alkaline-manganese dioxide cells, directly from Duracell®:

AAA—1,120 mAh
AA—2,450 mAh
C—7,000 mAh
D—14,250 mAh
9V—565 mAh

Below are some typical mAh capacity figures for 9 volt batteries at different current drains:

600 mAh @ 5 mA drain
560 mAh @ 14 mA drain
546 mAh @ 26 mA drain

You can see that the mAh figures will vary a bit depending upon the actual current drain, higher current drain giving less amp-hour life, but they're still a good guidepost for general usage. When you measure the current drawn by a particular piece of equipment, using Ken's battery paddle idea, divide that figure into the total capacity shown above for the size of cells you're using to get an approximate idea of the number of hours of use to be expected from those cells.

"You can drag out the shovel and split open the ground, but why not let nature do some of the work for you instead?"

No-drip 9913

From Chuck Steer WA3IAC: "Belden 9913® coax cable and its clones have been known to change from a nice dry transmission line into a water pipe after repeated soaking rains, compliments of Mother Nature. This can be the combined result of the cable itself having an internal 'air' dielectric, coupled with a non-watertight fit between the cable and its outdoor connector.

"I've solved the problem at my QTH by always using a length of 3/4"-diameter heat-shrink tubing over the finished connector's back end, then wrapping the entire connection with Teflon® self-adhering tape. If you don't have a heat-shrink gun, you can always 'borrow' the XYL's stove for a few minutes to acquire the heat needed to make the shrink tubing good and tight over the rear of the cable/connector interface junction. Don't depend upon overlapping tape alone to seal this critical point."

Moderator's note: Chuck has a couple of good suggestions here. For the heat-shrink-tubing part, I've also had excellent results with the type of heat guns generally sold in hardware stores or home improvement centers—intended for use in stripping paint or for thawing frozen pipes. There's the large "gun" style and also a smaller "point-source" style (my personal favorite) that will handle most jobs around the electronics workbench. They're usually quite a bit less expensive than heat guns sold specifically for heat-shrink-tubing applications alone, so if it's dropped, the loss isn't as great. I use one of the small "point-source" heat guns for applying concentrated heat to a circuit part that I suspect of being overly heat-sensitive, and in general troubleshooting as well.

Recycling is "in"!

73 reader **Andrew Gretchenuk** sent in this innovative idea, along with the samples shown in **Photo A:** "Whenever I go to a garage sale, house sale or flea market, I keep an eye peeled for any enclosures that might have ham radio or electronics applications. One of the ones that I particularly watch for is normally used in the kitchen, and consists of three or four wooden canisters of the style that 'nest' inside of one another for storage. They often make great little speaker enclosures or general radio project housings (for receivers, meters, test gear, etc.). To adapt them to a project, I'll usually use the scheme shown in **Fig. 2** to give me a metal 'partial chassis' for parts mounting. The spacers shown in **Fig. 2** can often be picked up at hamfests, or you can obtain them from parts suppliers such as Fair Radio Sales of Lima, Ohio (Tel. 419-227-6573) or

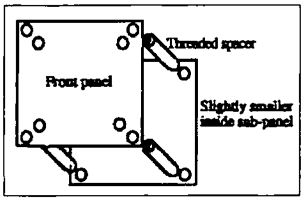

Fig. 2. Front panel and sub-panel (chassis) for use with a recycled kitchen storage box. See Andrew Gretchenuk's suggestion in the text for complete details.

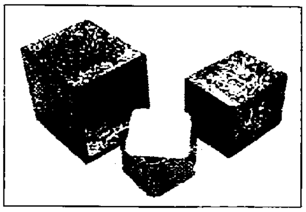

Photo A. The nested wooden kitchen canisters described by Andrew Gretchenuk are shown on the left and right sides of the photo. The repainted candy tin is in the center, painted "ham gray," of course!

The Electronic Goldmine in Scottsdale, Arizona (Tel. 1-800-445-0697). They can be obtained in various lengths from 1/4" on up.

"Another item to watch for at secondhand sales are metal cookie or candy tins. When repainted with metallic automobile spray paint, they often end up looking very professional and make excellent shielded enclosures (also shown in **Photo A**). Most are even directly solderable when buffed up a bit and soldering paste is applied."

Moderator's note: All good suggestions, Andrew, and thanks for sending the samples for photographing. Another source of handy very small "recycled" cases are those used to package Tic-Tac® breath mints; they'll hold a miniature remote toggle switch, a few small parts, or will act as a cable splice junction box. Either leave them transparent or apply a quick spray of your favorite color of "ham gray." It's best to put the mints inside of something else that doesn't make so much noise in your pocket anyway!

Pinned to the mat!

From Herb Foster AD4UA: "When the need arises to 'hide' radial wires or a small coax feed cable for an HF 1/4-wave vertical out on your lawn, here's a tip to keep in mind, one that I've used myself very successfully. Of course, you can drag out the shovel and split open the ground wide enough to accommodate those radial wires or RG-8X coax, but why not let nature do some of the work for you instead?

"Gather up a handful of wire coat hangers, the ones that seem to accumulate in closets as if they're breeding there! (I can't recall ever paying for a wire hanger... my XYL always seems to be able to produce a nice bunch for me upon request.) Once in

hand, use a sturdy cutter to clip off the hanger's normal 'hook' and straighten out the remaining length. Next, cut this straightened piece into 9" or 10" lengths and form a 90-degree (or more) bend—about an inch or so from one end—in each of these smaller lengths. Make up a bunch of these 'cable pins,' and push one down into the earth about every 15" or so along the radial or transmission line run. The 1" bend will 'pin' the wire closely to the ground and keep it there. If you've mowed the lawn somewhat on the 'short side' first, so much the better; the grass will grow up around the 'pinned-down' wire and your radials and transmission line will eventually almost disappear into the lushness of the turf. If done correctly, you'll be able to mow right over the radials and coax as if it weren't even there. This tip works equally as well at your home QTH as it does at a temporary 'ham-cation' spot!"

A better cube!

From Stephen Reynolds NØPOU: "Most of the inexpensive wall-mount plug-in DC power "cubes" that are available today have no internal regulation and will often sag to close to 50% of their labeled voltage when loaded to near their labeled current rating. Some items of equipment (if they have their own internal regulation) will work correctly when powered by these 'cubes,' but other items won't. Applying too much or too little voltage to certain accessories can be risky at best but here's a way around that potential (ouch!) problem!

"DC-to-DC automobile cigarette lighter adapters can be found that will lower and regulate the normal 12 volt DC car battery potential down to some other (often selectable) value... and these little gems can also be used on the 120 volt power 'cubes' mentioned above. Just be absolutely sure that you observe the correct input and output polarities, and that the current drain expected doesn't exceed the rating on either the power 'cube' or its DC-to-DC regulator add-on. Take a look at the Radio Shack™ catalog if you haven't seen the DC-to-DC adapters I'm referring to; the catalog shows several that are applicable."

Moderator's note: You might also consider building up a small external regulator using one of the many fixed voltage regulator chips on the market today. They're available in several size and current ratings and are extremely easy to put to use. The 78xx family of 1 amp positive voltage regulators in a TO-220 case (as shown in the drawing of ***Fig. 3****) can be commonly found in these standard fixed output values:*

7805T—5 volts
7806T—6 volts
7808T—8 volts
7812T—12 volts
7815T—15 volts
7818T—18 volts
7824T—24 volts

You can also incorporate an adjustable regulator, such as the LM-317T, shown in last month's column.

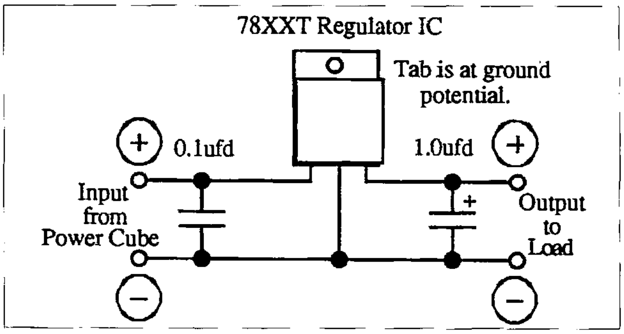

Fig. 3. *A 78XXT series regulator chip can also be used to stabilize the power output from an inexpensive DC wall power cube. See the "Moderator's note" with NØPOU's tip for further details.*

Fabulous ferrite

From Jim Kocsis WA9PYH: "Have you ever noticed how generally poor the AM sensitivity is on most of today's small portable transistor broadcast band radios? The sensitivity on the FM band is usually much better because this band uses either a telescoping whip antenna, or perhaps a fairly long headphone cord, allowing the capture of a reasonable amount of usable signal... but the AM band is a whole other story.

"The sensitivity on AM is limited by the effectiveness of the built-in ferrite rod antenna used for AM band pick-up. As the size of the radios has been shrinking, so has the ferrite rod's length—often ending up to being only a couple of inches long. I have a "super" AM radio that contains an 8"-long ferrite rod antenna, and it runs rings around the smaller radios... primarily because of the longer rod.

"Not wanting to have to carry the larger radio around, I decided to experiment a bit. I tried positioning just a ferrite rod, about 8" long, at various points around my little radio's case and found that reception could be markedly improved. You can find these larger ferrite rods at hamfests, garage sales or flea markets (the salvaged parts of older AM radios or perhaps the entire defunct radio itself). Simply strip off the coils of wire, then find the best spot on the outside of your small AM portable—where the signal is enhanced significantly—and using a rubber band to hold the 'auxiliary signal booster' in place, get ready for greatly improved performance. The flat ferrite form will give you the lowest profile, of course, but the round rods work well too. Be careful handling the ferrite material, it's very brittle and will easily snap if dropped or mishandled. Give the idea a try, it might just make you the 'hero of the day' to your wife or children (grandchildren?)."

This ends another month of "Ham To Ham." From KA9UCK (Sue) and me, all the best of the Holiday Season's joys and happiness. I hope that Santa brings you some interesting ham radio toys... remember, gals, men like toys as gifts, not clothes! We're actually just little boys in bigger jeans!

And now that winter has set in to stay for a while, why not sit down and write a brief description of some of the things that you've found useful in the pursuit of your own ham radio interests? I'll share them with the other *73* readers through this column in the coming months. Items of interest for spring and summer projects would also be appropriate to send in now... magazine lead times are fairly long. Please send all tips, suggestions, ideas and shortcuts to the address at the top of this column. See you next year! 73 de Dave NZ9E.

NEVER SAY DIE

Continued from page 49

looking forward to it. Most report coming into contact with a supreme being that radiates love. Most are told they have tasks to do on earth before going to "heaven" and so must return until it is their time. While most of them become more religious, few continue going to organized religion churches. They come back with the message that God isn't interested in theology. Most of them, while dead, undergo a life review where they experience what they felt and what the other people around them felt as a result of their actions. I have an ex-wife who's going to have a major problem with that, and not a few ex-employees.

Of course I can't help, while reading about these NDEs, looking back at my life to see how I might have done better. My total lack of interest in money has been a hardship for my wife, who is much more money-oriented. It's also been a magnet for those who would take advantage of my lack of interest and who have robbed me of millions. But, having (at least in my eyes) helped the world along with the development of cellular telephones, microcomputers, compact discs (better music), my record companies, and now (hopefully) with cold fusion, I feel my visit to earth has been worthwhile.

My love of amateur radio has been guiding me for most of my life. Sure, I get frustrated when I hear hams using bad language and being inconsiderate on the air. I almost got angry when the ARRL virtually destroyed the hobby 30 years ago in their move to generate greater visibility for the League with their so-called "incentive licensing." And my ability to forgive, forget, and love my enemies is sorely strained when people print lies and distortions about me. Shame on you, Fred.

Another, slightly older, book on NDEs is Dr. Moody's *The Light Beyond* (1988; $4.50; 205p). He even interviewed a number of children who'd had NDEs, with their stories all being quite consistent.

The reports are that a whole realm of the afterlife is set aside for the pursuit of knowledge. Well, I've got a good start in that direction. When I die it's going to take a trailer truck to bring my library... and I'm not going anywhere permanent without it. If I can't take my books and CD collection, I'm not going.

Closer To The Light by Dr. Morse (1990; $6; 237p) deals with children's NDEs. What does it feel like for them when they die? What do they learn? We're going to have to understand more about how time works because many NDE reports have to do with future events. You'll also enjoy Brad Steiger's *One With The Light* (1994; $5; 300p), which not only covers a wide variety of NDE reports, but shows how in every case the experience has substantially changed the people's lives.

If you've read very many biographies you know that many (most?) of our creative artists attribute much of their inspiration to the ineffable. Sousa said that all of his marches came to him when he was in a half-sleep state. They came full-blown, so all he had to do was get up and write them down. Many composers and writers tell similar stories. In *Neither Dead Nor Sleeping*, May Sewall (Bobbs-Merrill, 1920; 320p; $2.50 in an old bookstore) wrote that her deceased husband explained to her that spirits on "the other side" are responsible for these subconscious creative events.

There's a current spate of books about guardian angels. The recent TV programs on angels probably triggered this interest. In between reading Peter Graneau's *Ampere-Neumann Electrodynamics of Metals* I'll whip through Hope Price's *Angels*, a $5 Avon inspirational paperback which reports on hundreds of angel interventions. There are a bunch more angel books, all packed with stories of people who've been touched by them. Now, are you going to try and tell me that every single one of these people is totally mistaken? Give me a break!

No, I can't see auras or bend spoons, but I have no good reason to disbelieve the many people I know who claim to have done these things. There are a great many things going on that we have no good scientific explanation for. Can you assure me that not one person in history has ever been able to dowse? My grandfather, who was an inventor, taught me how to dowse. "Pop" was good at it. He also was a good inventor. You wouldn't see Citgo or Continental Can Company around today except for him. He knew a lot about everything, so I accepted dowsing and had no trouble learning how to do it when I was about seven. Alas, he was a heavy smoker, so he died when I was only 12. My grandmother, who didn't smoke, lived on almost 30 years longer. I'll have to tell you more about her sometime. She put me onto the Sewall book three years after she died.

Though I haven't had a near death experience, I still have a pretty good idea of what my mission in this life is. It's what I've been doing for the last 44 years as a publisher: sharing the things I've found fun and exciting with as many people as possible, and urging you to share what you've learned with me. So I'm on your case, urging you to do better. To lose weight and thus live a longer and happier life. To not smoke. And to be adventurous. To try new things. Go new places. Try packet. Try satellite communications. Try going on a DXpedition somewhere. Learn more. Read.

If your reaction is negative, remember that this could be an approach to life that you carry around with you. Life is more what you make it than a box of chocolates. If you're nasty, so will be the people around you. If you get on the air to have fun and meet new people, that's what you'll find, for the most part. When you run into an ill-mannered op try another frequency instead of getting mad or getting even.

One thing both the angel and the NDE reports all agree on is that prayer can be surprisingly powerful. It doesn't seem to matter what deities you believe in, just the act of praying has power to heal and change things. No, this is not a new concept and it doesn't mean that poor old aging Wayne is newly converted to any particular savior. I'm just telling you what thousands of people I've read about have reported.

As I'm writing this I'm thoroughly enjoying a CD of Louis Moreau Gottschalk's (1829-1869) music. His music was sort of a precursor of ragtime and he was the first internationally famous American composer. Though it's difficult for me to imagine, I suppose there are some people who might not find his music irresistible. His Tarantella, Résponds Moi, Ojos Criollos, Orfa, La Gallina, Bamboula, Grand Fantasia, and Pasquinade are incredible. If I can't get you to enjoy reading books and learning, maybe I can turn you on to some wonderful music. No, all you want me to write about is ham radio, right?

So what do you find the most exciting about amateur radio? What adventures have you had? If you've made even a hundredth the number of friends via the hobby that I have, it's paid off handsomely for you. That's probably what brings me back to Dayton almost every year. When's the last time you had a contact where you talked with someone for over an hour and you both hated to end it? I used to offer a certificate for long-winded contacts, the Real Rag Chewer's Club certificate (RRCC) for contacts over an hour. Let me know if I should offer that again.

Of course I used to offer a WAAS certificate for hams who'd worked 49 states. Worked Almost All States. Then there was my CHC Certificate Hater's Club for hams who hate certificates and promise not to go after them, and if they do, by chance get one, they promise to hate it.

Maybe it's best I don't write about amateur radio and just stick to my secret goals of trying to get you to have more fun, to learn, and shape up.

Grist

With several hundred of the Art Bell listeners sending for a book of my not-yet-published 73 editorials, I started rummaging through the back issues, pulling out my non-ham oriented comments and putting them together into books of about 50 editorials each, *Grist I* and *Grist II*. If you enjoy my stuff you might send for a few copies of these for any friends you have who might enjoy thinking. Yes, I expect this is pretty restrictive. When I think over most of my friends, hams or not, darned few of them seem to be much interested in thinking.

Maybe that's why, when I get someone on the phone or over the air who's obviously done some thinking and the homework to back it up, we can talk for hours. Golly, that's fun!

Anyway, Professor Green has been reading and thinking, and putting his reports into these editorials. I think you'll enjoy the

Some Hands-On Fun

With the start of a new school year, most teachers and instructors of ham radio classes are looking for new activities and demonstrations to do in the classroom. Experience shows that hands-on demos and experiments are the most fun and therefore the most memorable to the children. This term I tried something new.

I allowed one of my classes to pick their own hands-on activity to demonstrate to each other. Each group consisted of four team members. They had two weeks to prepare a demo to present to the class. They had to research the activity and come up with an interesting presentation about the unit we were studying, which was about batteries.

Obviously, the criteria for setting up the groups and for the complexity of the project will be determined by the age and ability of the group. But the sixth-graders I did this with really seemed to love the idea of coming up with their own project. I gave them time to spend in our class research center and for "putting their heads together." They were off and running to local libraries as well.

The charts and diagrams that were submitted were simply excellent. Here are two of the eight activities that were very well received by the children.

How do batteries work?

"How Do Batteries Work?" was presented by two boys and two girls in the sixth grade. Justin had big illustrations of the inside of a battery and explained to the class that a dry cell battery consists of a zinc container, a chemical paste, and a carbon rod. A chemical reaction involving these three materials produces electricity. The battery stops working when all the materials dry up inside the battery. In rechargeable batteries the chemical reaction can be reversed.

Photo A. Sixth-grader Mike sets up a circuit with wires and a battery.

For this demonstration you'll need the following items: an LED, two dishes, vinegar, two pieces of zinc (silver coins may work), two pieces of copper (pennies may work) and wires. In this activity, the vinegar acts like the paste inside a battery. Lemons or pickles work as batteries just as well as vinegar. The metals and vinegar react together to produce electricity.

Set up the circuit with a piece of zinc and copper in each dish of vinegar. When the LED didn't glow at first, we connected it to the wires in the other direction, using alligator clips. The kids really had a good time trying the same demonstration with the lemons and pickles. Always remember that being able to have children associate learning with fun is a number one priority in the classroom.

Tanisha did her part by giving a brief background on the "First Batteries." She explained that in 1791 the Italian scientist Galvani noticed that a leg from a dead frog twitched when touched by metal instruments. Electricity was flowing between the metal and the fluids in the leg. This effect was seen by another scientist, Volta, who went on to invent the first battery. He used stacks of zinc and copper disks, separated by fabric soaked in saltwater.

Sockets and switches

The second demonstration had lots of illustrations to go along with it. Making clear and informative charts is a whole unit by itself with the sixth grade. This one was called "Sockets and Switches." Materials needed are: two wires with alligator clips, a bulb (2.5V) and socket, a battery (1.5V) and holder.

Henry reminded the class that electricity can only flow along an unbroken path. The battery pushes electricity all the way around the circuit. The voltage written on a battery tells you how hard the battery will push electricity around a circuit. If you double the number of batteries in a simple circuit, you double the voltage pushing the electricity around.

First the kids screwed the bulb into the socket. Next they put the battery in its holder, then connected the wires to form a circuit. The next step in this interesting demo required an extra wire with alligator clips, tape, foil, and a thick piece of cardboard. They proceeded to add the extra wire into the circuit. Then they made a switch by taping pieces of foil to the cardboard so that they overlapped. Next they connected the foil to the circuit with the free alligator clips. They could then make the bulb flash by touching the pieces of foil together.

Take a guess what this demonstration was the introduction to in my ham radio class. In my next column I'll report on some very simple hands-on telegraph keys. If you are a teacher who has done some exciting activities with ham radio classes, please send me the details along with the children's pictures so that we can share it with other instructors.

Number 63 on your Feedback card

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine,* Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the February 1997 classified ad section is December 12th, 1996.

UNIQUE HAND-CRAFTED CALL SIGN PLAQUES. Rustic pine board hand painted by artist with 20 years experience. Send SASE for free brochure with design descriptions, **Hamprints**, P.O. Box 23, Mark IL 61340. BNB5002

BRIGHTEN UP YOUR SHACK! Eleven page Compendium filled with ideas, tips, and instructions for building Illuminated Maps. Send $5.00 (TX res. add $0.41 tax) to **Pineapple Paradise Radio Co.**, P.O. Box 370692, El Paso TX 79937-0692. BNB6005

Large assortment of used test equipment. Most instruments are priced at 10% of original cost or less. Request list. **Jim Stevenson**, 3401 Sunny Slope Road, Bridgewater NJ 08807. (908) 722-6157 Fax: (908) 722-6391. BNB2084

MORSE CODE COMPUTER INTERFACES $49.95, with CW Filter $79.95, Free Shareware and Ham Catalog. **Dynamic Electronics**, Box 896, Hartselle AL 35640, (205) 773-2758, FAX (205) 773-7295. BNB1034

RF TRANSISTORS TUBES 2SC2879, 2SC1971, 2SC1972, MRF247, MRF455, MB8719, 2SC1307, 2SC2029, MRF454, 2SC3133, 4CX250B, 12DQ6, 6KG6A, etc. **WESTGATE** 1-800-213-4563. BNB6000

IT'S BACK! The return of the HW-8 Handbook! Second printing. Modifications for the Heath QRP rigs. First class mail $11. DX add $4 for air mail shipping. **Mike Bryce WB8VGE**, 2225 Mayflower NW, Massillon OH 44647. BNB404

MAHLON LOOMIS, INVENTOR OF RADIO; by Thomas Appleby, (Copyright 1967). Second printing available from **JOHAN K.V. SVANHOLM, N3RF, SVANHOLM RESEARCH LABORATORIES**, P.O.Box 81, Washington DC 20044. Please send $25.00 donation with $5.00 for S&H. BNB420

collections of my past editorial musings. The books are $5 each. A steal. I'll bet you know a few people who might enjoy them. Great Christmas gift. Cheap, too.

Ham Radio Fun

Communications Simplified, Part 12

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

The concepts of spread-spectrum date back some 50 years, and maybe more, but until recently the circuitry required to use it was so expensive that only the military found it feasible. In the last few years, however, spread-spectrum equipment has become quite common in many areas.

Consider the following example: Suppose your name is Kilroy, you were supposed to meet a friend in some room, and you want to leave him a message that you've come and gone. The problem is that you have an enemy, and you don't want her to know you've been there.

You could scribble "Kilroy was here" on the wall, but that's too obvious. (Besides, graffiti is ugly!) So you decide to leave a little note that reads KILROY WAS HERE. The problem is—where to put it?

You don't want your enemy to know that you left a message. Even if she knows, you don't want her to find and read it. Worse yet, your enemy might remove it, or perhaps change it to read KILROY WILL BE HERE. Or someone completely new might come into the room, need a piece of paper to write on, and scribble all over your note.

This is a problem that is faced by the military. When sending an important message:

(a) You don't want the enemy to know about it;

(b) If he knows about it, you don't want him to be able to read it;

(c) If he can read it, you don't want him to change it into something quite different; and

(d) You don't want a transmission from your enemy, or even someone else, to interfere with your message and prevent it from getting through.

So back to the room. You spot a telephone directory lying on the table, so you write your KILROY WAS HERE message into it. You put the K on page 55, the I on page 113, the L on page 38, and so on. In other words, you spread your message throughout the directory, hiding it amid the printing that's already there.

In order to find your message, someone would have to know exactly where to look for it. Your enemy won't know that; in fact, she may not even notice the extra few letters written in amongst the "noise" of all the other stuff in the telephone directory. But even if she notices the extra printing, she won't know the order to put the letters back into. (Obviously, though, you'd better tell your friend where to look!)

Now suppose someone else comes into the room and decides to leave another message in the phone book. This new person is very unlikely to pick the exact same pages that you did, so the new message will probably not interfere with yours. Even if, by some chance, a few of the page numbers he chose happened to be the same ones you already used, at most he might overwrite one or two of your letters. Your message might now read KILXOY WAR HERE, but that's still enough to get the message through—better than putting your entire message in one place and taking a chance on its all being obliterated.

This silly little example is actually quite useful in answering some basic questions. For example, how should you pick the page numbers on which to write? There are several ways:

(a) Roll some dice to get completely random page numbers. Nice, because that makes it really tough for someone else to figure out the sequence. It also helps to spread the message throughout the entire phone book. But now you will have to give the list of page numbers to your friend. These numbers would be random if there is no pattern to them—even knowing all the past numbers that were used, you can't predict the next few numbers.

"How should you pick the page numbers on which to write?"

(b) Build two sets of loaded dice—one for you, one for your friend—set up so they both roll the same numbers. You roll your dice to get a set of page numbers. Later, your friend rolls his set of dice in exactly the same way, gets the same numbers and bingo. These page numbers look random, but actually they are not—if you have the loaded dice (or know how they were built), you can duplicate the set of numbers at any time. Such a set of numbers is called *pseudo-random*.

(c) Come up with some other way of generating pseudo-random numbers. For example, there are digital circuits that can generate long strings of digits that

look random, but are not. Or there are math formulas that can do it. As long as you and your friend both have the same circuit or formula, you can duplicate the same sequence of page numbers.

(d) If you need to do this every day, should you reuse the same numbers each day, or should you start over with a different set? If your main aim is secrecy, then you should use a different set each day. But if you're just concerned with keeping down interference from or to other people, then reusing the same numbers every time can be enough.

Now let's see how this applies to radio signals. The traditional idea is to transmit a radio signal on a carrier with a fixed frequency, and to try to limit the bandwidth as much as possible to avoid interference to (and from) others. But a radio signal like this is easy to find (especially with a spectrum analyzer), and easy to interfere with or jam.

Spread-spectrum radio, on the other hand, takes that signal, spreads it over a very large band of frequencies, and does it in a way that looks quite random and unpredictable (but is not!) It is the very opposite of what communicators have been trying to do since the beginnings of radio.

Spreading a signal out over a large band of frequencies also has the effect of bringing it down into the noise. Consider a glass of water. If the glass has a diameter of, say, two inches, then it might be perhaps four inches tall. Pour the same amount of water into a glass four inches in diameter, and the water is now only one inch deep. Pour it on the basement floor and it spreads out over a large area, but becomes only a tiny fraction of an inch deep. In the same way, a 10-watt RF signal all on one frequency stands out like a sore thumb. Spread it out over a few megahertz, and the amount of power at any one frequency is so small that it's almost impossible to measure. It blends into the noise.

There are several different ways to spread the signal over a large bandwidth; the two most common are frequency hopping and direct sequence.

Frequency hopping

Frequency hopping is just what the name says—rather than continuously transmitting on one frequency, the transmitter is constantly hopping from one frequency to another. This can easily be achieved by using a pseudo-random number generator to drive a phase-locked loop. Both the transmitter and receiver must use the same number generator to make sure that each time the transmitter hops to a new frequency, the receiver will go there too.

Your signal actually uses a lot of bandwidth—it spreads out over a large spectrum—but any particular part of that spectrum is used only a bit. Not only is it hard to find such a signal, but it generates relatively little interference to others because it never stays on any one frequency long enough to really bother anyone. It also *picks up* little interference from others: If there is some other interfering transmitter on a particular frequency, your receiver will be on that frequency only a short time, probably not long enough to bother you or him. (And some frequency-hopping systems actually avoid frequencies that are in use by other systems.)

Frequency hopping can be used to send an analog voice signal, but during the times that the transmitter and receiver are hopping from one frequency to another, there would be short breaks or glitches in the signal which would be very annoying. So a more common approach is to use a *codec*—a coder/decoder which does an analog-to-digital conversion to change the analog voice signal to digital data—and then send the digital data in short but rapid bursts. Between the bursts the transmitter shuts off, switches to the new frequency, turns on, and then sends the next burst of data. The receiver collects the bursts of data, slows them down and converts them into a continuous stream of data which, when converted back to sound with another codec, results in continuous speech.

This method has one other advantage: Once the sound is in digital form, error correction can be used to correct for missing or wrong bits of data. In this way, even if two transmitters occasionally hop on the same frequency and interfere with each other, the error correction removes the resulting errors.

Direct sequence

Direct sequence spread-spectrum is completely different from frequency hopping. Let's go back to our analogy of

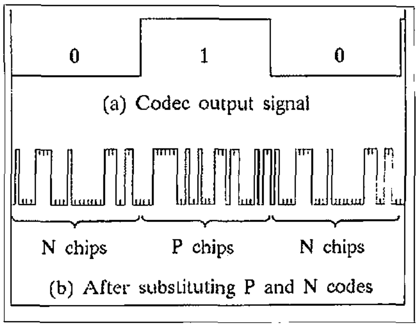

Fig. 1. Spread-spectrum chips.

hiding messages in a telephone directory. As we described it, each successive letter of the message KILROY WAS HERE went on a different page. This matches frequency hopping quite well, where each successive part of a signal is sent on a different frequency.

Direct sequence spread-spectrum (DS-SS) is not like that. Imagine that the telephone directory has 100 pages. Take K, the first letter of the message, break it up into 100 pieces, and put a little piece of it on every page of the book. Then do the same for every other letter of the message. At the end, every page of the directory has a tiny bit of every letter. In a sense, your KILROY WAS HERE message is smeared all over the book! That's direct sequence!

Let's use a spread-spectrum cordless phone as an example. Suppose you want to transmit a telephone-quality voice signal having a bandwidth of perhaps 3000 or 4000 Hz, between the handset and the base of the phone. With ordinary AM or FM, it could be sent in a radio signal with a bandwidth as narrow as 6 or 8 kHz (and even less with single-sideband.) With DS-SS, the process is a lot more complicated. We start by converting the voice signal into a digital signal with a codec. This typically gives us 64k bits per second of digital data.

DETOUR

A quick review: For resistors, a k is 1,000 ohms. For computer folk, however, a k is 1,024, so 64k would normally be 64 x 1,024 or 65,536, not 64,000. In this case, however, the number really is 64,000 bits per second, obtained by multiplying 8,000 measurements per second times 8 bits per measurement.

END OF DETOUR

If we ignored the fact that the 64k bps output of the codec has sharp edges (and therefore harmonics) and tried to modulate this onto a carrier the pre-spread-spectrum way, we would have a total bandwidth of 64 kHz.

Direct sequence spread-spectrum takes an extra step, however, before it modulates the carrier. It takes each bit of the data coming out of the codec and replaces it with a whole batch of new bits. In a typical spread-spectrum cordless phone, for example, each bit of the codec output is replaced by 32 bits. These bits break up each codec bit into 32 pieces called "chips." One set of 32 chips, called the *N code*, replaces each 0, while another set, called the *P code*, replaces each 1 in the codec output. In **Fig. 1 (a)**, we see the signal as it might come out of the codec. In **Fig. 1 (b)** we see what happens when the N code replaces the two 0 bits, and the P code replaces the 1. (In this figure, the N code for the two zeroes is the same; for greater security, more complex systems might change the P and N codes from bit to bit.)

"This can easily be achieved by using a pseudo-random number generator to drive a phase-locked loop."

Obviously, the resulting signal has much higher frequency components; in general, replacing the original bits with their P and N codes increases the frequency range by a factor of 32, which increases the bandwidth by a factor of 32 as well. In this case, the bandwidth goes from 64 kHz to over 2 MHz, much more than before. But this means that the transmitted power is spread out over a much wider bandwidth—sort of like spilling a glass of water on the floor. The same amount of power (or water) is still there, but by spreading it over a larger area the depth at any spot is very small. In some cases, the power may be so small that it's at or even below the normal noise level.

As you can imagine, a direct sequence spread-spectrum receiver is an interesting device. It starts off with a fairly normal superhet design, except that the bandwidth has to be wide—as wide as the signal. All of the interesting work occurs after the detector. Because the transmitted signal is spread out over such a wide bandwidth, the output from the detector (usually a phase-modulation detector) looks very much like noise. It would be almost impossible to recover the desired signal, except for one thing—the receiver knows what the P and N codes are supposed to look like! So it knows what to look for.

The circuit that looks for the P and N codes is called a correlator. *Correlation* is a mathematical term which describes how similar two things are to each other by comparing them, item by item. For example, suppose you toss a coin four times and get tails, heads, heads, and tails; call this THHT. If your friend tosses a coin and also gets THHT, that's a perfect match. You both got tails on the first toss, heads on the second, and so on. But note that this is not the same as THTH. THTH also has two heads and two tails, but they aren't in the same places—the first and second toss were the same, but the third and fourth are different. So only half of the tosses matched.

Now, suppose you toss a coin 100 times, and your friend also tosses 100 times. On the average, you'd expect 50 of your friend's tosses to be the same as yours, and 50 to be different. So if you get somewhere around 50 matches out of the 100, that doesn't show anything special; that's just the way random events happen. We'd say that this is *uncorrelated.*

But if all 100 of your friend's tosses exactly match all 100 of yours, that's suspicious. Sort of like two students who take a true-false test in a subject they know nothing about, and get exactly the same answers (some right, some wrong.) Suspicious, right? I would say that these two sets of answers are correlated—that one student probably copied his answers from the other. That's a correlation of 100% (or just +1.)

But what if the two students get answers that are completely different? Each time one answers TRUE, the other answers FALSE. I'd say that's also suspicious—almost as though one copied from the other, but purposely changed his answers because he decided the other chap was always wrong. In our case, we'd say this is -100% correlation (or just -1.)

So if two signals are very similar, the correlation is close to +1; if they are opposites, the correlation is -1; if they aren't related to each other, the correlation is 0.

Now back to a very simplified explanation of the direct sequence spread-spectrum receiver. The signal coming out of the detector is noisy, but at any instant that noise might be positive or negative. This voltage is sent to a capacitor, which averages that voltage over the length of one chip. At the end of that time, the capacitor voltage may be slightly positive or slightly negative, and the circuit uses that voltage to decide whether that chip seems to be a 0 or a 1. It then sends that chip into a digital circuit which stores it, as well as the 31 previous chips. In other words, this circuit (called a shift register) stores the last 32 chips that have come out of the detector. (The shift register always stores the latest 32 chips; each time a new chip comes out, the oldest chip in the register gets pushed out, so the very last 32 chips are always in the register.)

Now the correlator goes to work. The receiver knows what P and N codes the transmitter is using. So the correlator continuously looks at the 32 bits in the shift register, and compares them bit-by-bit with the 32 bits in the P code and the N code that it knows the transmitter used. Each time it finds a match, it says, "Aha! I got one!" (For those of you mathematically inclined, this process is called *convolution.*)

With 32 bits in a P or N code, there are 2^{32}, or more than four billion possible patterns to the code. So it's not likely that a random signal coming out of the detector is going to exactly match either the P code or the N code. For that matter, since the

incoming signal is noisy, it's not likely that even a fairly *strong* transmitted signal will exactly match the P or N code either. But if most of the bits match (and it's up to the designer to define what is meant by "most"), then the correlator reports that it has recognized a 0 or a 1.

So let's just review some of the key points of the system:

1) The correlator sort of takes a majority vote on the chips, so it tolerates a certain amount of errors. Even so, it will often make a mistake, so some additional error correction is usually needed.

2) The P and N codes have to be different enough that there isn't a likelihood of mistaking one for the other. Even their parts have to be different, and this means that only certain P and N codes can be used. Still, there are many possible combinations.

3) A receiver can only decode a transmitted signal if it knows what P and N codes the transmitter used. Other transmitters using different P and N codes, even though operating on the same frequencies, appear as just noise. While they increase the overall noise in the system, they don't really interfere with reception unless they are very near. Thus, many transmitters can use the same frequencies without interference to each other, and they are often difficult to detect.

The FCC has recently opened up three bands (902-928 MHz, 2400-2483.5 MHz, and 5725-5850 MHz) for unlicensed spread-spectrum operation. A variety of equipment, such as wireless headphones, cordless phones, burglar or fire alarms, and wireless modems, are already being marketed. There are even some integrated circuits which contain most of what you'd need for a simple spread-spectrum transceiver. Moreover, direct sequence spread-spectrum (under the name CDMA or Code Division Multiple Access) is being developed for cellular telephones as a means of allowing many more telephones to be used in a given area without interfering with each other. This is a big field, and getting bigger.

Digital signal processing

Another interesting new concept which may drastically change radio systems in the very near future is digital signal processing. A DSP (Digital Signal Processor) is essentially a specialized microcomputer IC, dedicated to processing analog signals. It takes an analog signal, converts it into digital numbers, processes the digital data in some way, and then converts it back into an analog signal.

Up until now, DSP circuits have been used in amateur equipment primarily to process the audio. For example, a DSP can analyze the received audio to identify constant signals (such as the whistles produced by interfering stations) and remove them. It can do the opposite too—identify those signals which represent voice signals, and amplify them more than other signals. In this way, the DSP has been used primarily to remove interference and noise.

As another example, several companies now manufacture noise-reduction headphones. Mounted on the headphone is a small microphone which picks up outside noise. A DSP circuit analyzes that noise, and then sends an equal but opposite signal to the headphone. This opposite signal partially cancels out the outside noise, reducing the noise level. The concept has also been used to counteract machinery noise.

Up until recently, DSPs have been plagued by slow speed, with the result that they could barely keep up with audio frequencies. But recent advances in DSP technology have speeded them up to the point where they are becoming fast enough to work at IF frequencies in receivers. This opens up an entire new area for them.

A number of manufacturers are working on receiver designs that consist of just three analog parts—an RF amplifier, oscillator, and mixer. The IF output from the mixer would then immediately be digitized by a DSP, and all other functions, including IF amplification and filtering, and detecting, would be done digitally.

The idea is actually driven by cellular radio. A cellular site normally needs a number of receivers, all tuned to different frequencies. Using DSPs would eliminate all this, replacing it with one RF amplifier, one oscillator, and one mixer. The resulting IF signal (which would actually contain a number of different received signals at the same time) would then be processed by several different DSPs, each one recovering the signal from one mobile or handheld cell phone user. When a cell phone switches from one frequency to another, instead of the cellular site having to switch receivers, the DSP would simply be reprogrammed to recover a different signal.

"Today's criminals can use these same techniques to avoid detection and capture."

The whole concept is still brand-new, and in its infancy. But we can expect the typical radio receiver five or 10 years from now to be very different from today's superhet!

Conclusion

As you can see, interesting and exciting things are happening in radio today. The advent of spread-spectrum communications is turning the industry around. Forty years ago, when CB or Citizens' Band radio started, so many people started using it that interference (and bad operating) made the band a shambles. Now spread-spectrum makes it possible for large numbers of people to share the same spectrum space without really interfering with each other.

Potentially, this is a tremendous improvement, but it can also lead to some problems. Just like the military developed spread-spectrum use over the years to provide security from detection, so today's criminals can use these same techniques to avoid detection and capture. I guess there isn't much we can do about that.

CW Enhancer

Making your signal stand tall.

Parker R. Cope W2GOM/7
8040 E. Tranquil Blvd.
Prescott Valley AZ 86314

When we listen to CW we would like to hear a "single signal," which means eliminating all the interfering signals. Eliminating all the undesired signals isn't really possible and we have to be satisfied with making the desired one stand out from the crowd. The filter described here does just that. It is tunable from below 300 Hz to above 3 kHz and has bandwidth variable from below 50 Hz to more than 5 kHz. The filter may strain out the signal but it doesn't strain the budget. It uses only one quad op amp (an LM324, available from Radio Shack™) and a few common resistors and capacitors.

Design equations are given to permit building filters for other applications in the audio frequency range. Of course, it's not necessary to understand the theory to build a filter that can improve your receiver's performance, but understanding the parts' functions allows adaption and use of the parts at hand.

The best filter for a receiver is a compromise of performance, complexity and cost. At first it would seem that a filter passing only a very narrow band of frequencies would be ideal. But using a very narrow filter in a receiver requires a slow tuning rate—if the receiver is tuned too quickly it can pass over a desired signal. A narrow filter also requires frequency stability in both the receiver and the transmitter. Some receivers drift for a few minutes (or hours) before they stabilize, and who can tell what the transmitter might do?

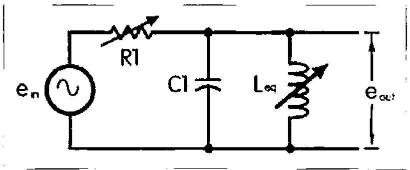

Fig. 1. A conceptual audio filter.

The CW Enhancer's center frequency and bandwidth can be adjusted to accommodate varying band conditions, and it has adjustable off-frequency rejection which is achieved by combining a portion of the full-bandwidth audio output of the receiver with the narrowband output of the filter. The narrowband signal is enhanced when the level of the full-bandwidth signal, including interference, is reduced relative to the narrowband signal.

"The active filter probably offers the best compromise for a multi-octave audio filter."

Filters come in many shapes and sizes, each with its own set of advantages and disadvantages. All things considered, the active filter probably offers the best compromise for a multi-octave audio filter. The CW Enhancer is an active filter that requires no matched components and only one low cost quad op amp, one variable resistor to control frequency, another to control bandwidth, and a pot to control enhancement.

The conceptual audio filter shown in **Fig. 1**, while not particularly useful when a wound inductor is used, can serve as the prototype for a filter when an active variable inductor is used. The output across the tuned circuit is maximum at the resonant frequency. The resonant frequency of the filter is:

$F_o = 1/[6.28 \times (L \times C1)^{0.5}]$

where F_o is frequency in hertz, L is inductance in henries, and C is capacitance in farads. L can be found by rewriting the equation as:

$L = 1/[(6.28 \times F_o)^2 \times C1]$

The value of L needed to tune C1 from 300 Hz to 3000 Hz can be calculated with the second equation. C1 is arbitrarily chosen to be 0.01 µF and the value of L is found to be:

$L_{max} = 1/[(6.28 \times 300) 2 \times 1 \times 10^{-8} = 28.1H$

$L_{min} = 1/[(6.28 \times 3000) 2 \times 1 \times 10^{-8} = 0.281H$

The 3 dB bandwidth of the filter in hertz is:

$BW = 1/(6/29 \times R1 \times C1$

where C1 is in farads, and R1 is in ohms. When C1 is fixed, the bandwidth of the filter is controlled by the variable resistor, R1:

$R1 = 1/(6.28 \times C1 \times BW)$

Assume C1 is 0.01 µF, then a bandwidth of 50 Hz requires R1 to be 318k. The nearest standard potentiometer value is 500k. Therefore, when R1 is 500k, the nominal minimum bandwidth is 32 Hz. When R1 is 5k, the bandwidth is 3.2 kHz. A resistor in series with R1

will limit the maximum bandwith if the range of bandwidths needs to be restricted.

In the CW Enhancer the variable inductance shown in **Fig. 1** is synthesized with a General Impedance Converter (GIC), shown in **Fig. 2**. The GIC, comprised of A2, A3, R2, R3, R4, R5, and C2, replaces the inductance L. The inductor synthesized by the GIC has an equivalent inductance of:

$L_{eq} = C2 \times R2 \times R4 \times R5 / R3$

where L_{eq} is in henries, C2 is in farads, and the Rs are in ohms.

"The best filter for a receiver is a compromise of performance, complexity, and cost."

Since R2, R3, R4, and C2 can be made constant, the inductance L_{eq}, and consequently the tuned frequency, F_0, can be controlled by R5. When R2 = R3 = R4 = R5 = R the expression for L_{eq} reduces to:

$L_{eq} = C2 \times R^2$

The value for R^2 can be calculated to show the general range of values of the resistors required in the GIC. A convenient value of C2 is 0.01 µF and R^2 is calculated to be 2.81×10^9 to produce 28.1 H. Therefore, R is approximately 53k . Since 50k is the nearest standard pot value available for R5, R2, R3, and R4 are recalculated to be 56k. The value of R5 needed to produce 0.281 H is 500 ohms.

The CW Enhancer shown in **Fig. 3** uses a GIC to synthesize a variable inductor to resonate with C1 over the frequency range. The bandwidth is controlled by R1. A fraction of the full bandwidth audio signal, determined with the enhancement control R6, is summed with the output of the resonant circuit. The resonant circuit is isolated from the summing amplifier A4 by the non-inverting unity gain buffer A1. The "enhancement" control, R6, controls the level of the full bandwidth signal without changing the level of the filtered signal.

The output of A4 can drive 20 mA into a short circuit or swing a 1k load to within a volt of the rails. This equates to about 1.5 mW into low impedance (8 ohm) phones or 20 mW into 600 ohm phones. For more audio power Radio Shack's mini-audio amplifier P/N 277-1008 at $11.99 will certainly do the job, but a simple emitter follower as shown in **Fig. 3** is much less expensive and is adequate for most situations. The speaker or phones are capacitively coupled to eliminate DC in the load. A 100 µF coupling capacitor produces a low cut-off frequency of 198 hertz with an 8 ohm speaker. That is, the response at 198 hertz is down 3 dB (half power) from the response at 2 kHz. When 600 ohm phones are used, the coupling capacitor can be reduced to 2.2 µF.

The LM324 quad op amp shown in **Fig. 3** is pin-for-pin compatible with the MC4741. These ICs contain four independent operational amplifiers identical to the MC1741 packaged in one 14-pin DIP. Of course, the quad op amp can be replaced with four individual 741s if they are more available.

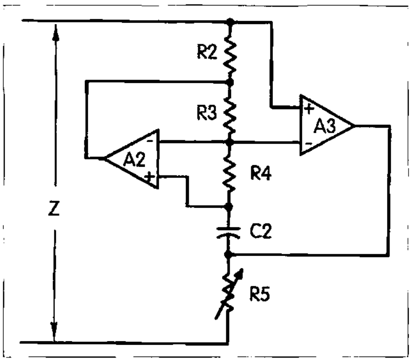

Fig. 2. The General Impedance Converter can look like an iductor. See text for formulas.

The power supply for the circuit is not especially critical; a 12 volt supply is convenient. When a 12 volt supply is tapped at 6V, the tap may be considered "local ground" and the op amps effectively operate from +6V and -6V. Of course, the +6V and -6V supplies could be developed idividually. The "local ground," V_R, is obtained by tapping a single 12V supply with R10 and R11 in **Fig. 3**. The +12 volt input is 6 volts above "local ground" and the

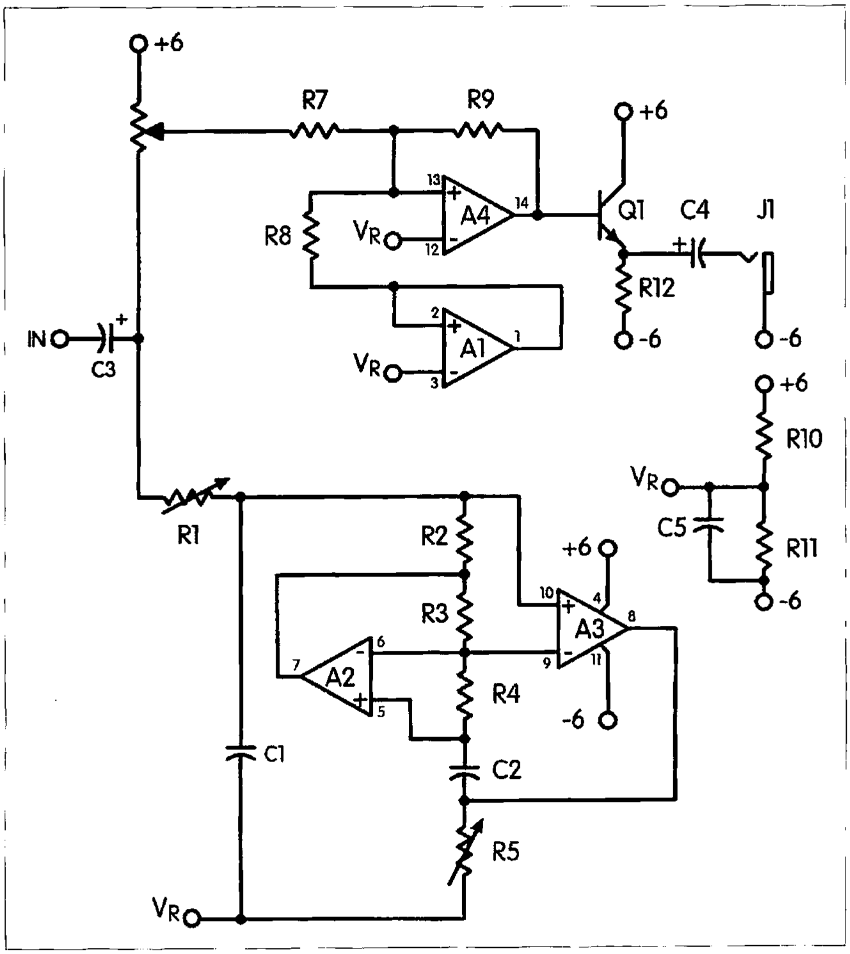

Fig. 3. The CW Enhancer uses GIC to synthesize the inductor in an audio filter..

negative side of the input supply is 6 volts below "local ground."

The maximum power into 600 ohm phones is limited by the supply voltage. With 8 ohm phones, the maximum power is limited by the peak transistor collector current. A different transistor with higher collector dissipation could supply more power if needed. Since the Enhancer's voltage gain is about unity, the maximum input from the receiver should be limited to about 3.5V (5V peak) with 600 ohm phones or 0.28V (0.4V peak) with 8 ohm phones or speaker.

The Parts List for the CW Enhancer of **Fig. 3** is given in **Table 1**. Most Radio Shack stores will special order the potentiometers from Radio Shack Unlimited (RSU). If not, they are available from any industrial electronics distributor, such as Digi-Key.

The CW Enhancer is a relatively simple project whose performance belies its simplicity. The three controls: "Enhancement," "Bandwidth," and "Frequency," enhance the CW capabilities of a basic communications receiver. Construction time is just an evening or two but the enjoyment it brings goes on and on.

Parts List

C1, C2	0.01 ± 10% µF film capacitor	Radio Shack # 272-0165
C3	2.2 ± 20% µF electrolytic capacitor	272-1435
C4, C5	100 µF electrolytic capacitor	272-1016
J1	1/4" single circuit 2-conductor phone jack	274-252
Q1	NPN transistor, $h_{FE} > 40$	MPS3904
R1	500k ± 20% 1/4W potentiometer	RSU
R2, R3, R4	56k ± 5% 1/4W fixed resistor	RSU
R5	50k ± 20% 1/4W potentiometer	271-1716
R6	5k ± 20% 1/4W potentiometer	271-1720
R7, R8, R9, R10, R11	10k ± 5% 1/4W fixed resistor	271-1335
R12	470k ± 5% 1/4W fixed resistor	271-1317
U1	LM324 quad op-amp	276-1711

Table 1. Parts list for the CW Enhancer.

Bill Brown WB8ELK
138 Angela Dr. Apt. B
Madison AL 35738

Just before sunrise on September 22, members of a group called HALO (High Altitude Lift Off) gathered at the old airport in Huntsville, Alabama, to fly an unusual balloon mission. This was part of an ongoing series of test flights to prepare for a rockoon flight this winter. The rockoon is a rocket launched from a balloon platform floating at 90,000 feet. Since this is above most of Earth's atmosphere, the rocket should fly briefly into space (over 60 miles high).

Also attached to the fuel tank payload was a low-power tracking beacon designed by myself WB8ELK, with a 68HC811E2 microcontroller which sent down CW altitude and temperature telemetry via a 147.45 MHz 2 milliwatt FM transmitter (audio CW) based on the Motorola MC2833P chip. In addition, the telemetry was simulcast on 28.800 MHz CW (20 milliwatts) using a keyed clock oscillator.

The balloon used was a special 19k cu.ft. Raven zero pressure balloon, which is quite different from the standard weather balloons used in previous flights.

"It was just like taking an elevator to the edge of space."

The flight system

The experiment payload consisted of a nitrous oxide fuel tank with pressure and temperatures probes inside to study the effects of the balloon flight. We need to maintain good pressure in order to fire our hybrid rocket from the balloon. The rocket is a hybrid consisting of a nitrous oxide tank and asphalt. Our ground-based launch of the rocket achieved nearly 30,000 feet last spring.

The ATV/telemetry payload was built by Ed Myszka KE4ROC and consisted of a live color TV camera hooked up to a PC Electronics KPA-5 ATV transmitter on 434 MHz (a microphone was attached to the audio subcarrier), a big wheel antenna built by Gobe W4WAD, and a sensor decode system consisting of two Basic Stamp IIs hooked to a GPS/Pico-Packet combo. Telemetry and position information was sent down in an APRS format on 145.79 MHz.

Ed mounted all of his electronics into a sturdy but reasonably lightweight aluminum frame of his own design and covered it all with Styrofoam™ for thermal insulation.

This balloon is made out of a plastic film with a vent duct in the bottom. At altitude, instead of bursting, it actually vents out the excess helium and will level off until sundown or until we cut it loose with a cutdown device.

Adventures in flight

As we laid out the balloon (70 feet long uninflated) on the pavement of the old airport runway, many of us commented on just how perfect the conditions were for our first attempt at such a large system. Not even the slightest breeze disturbed our efforts as we pumped almost four tanks of helium into the balloon envelope (approximately 1,000 cubic feet of gas).

After about two hours of preparation we were ready to launch. The balloon towered over us and was quite a spectacular sight as it reflected the early morning light. However, just as we were ready for liftoff, we encountered a problem with our rigging and retrieval system which required a trip back to the workshop to get some parts.

We sat there with a huge bag of helium for nearly an hour. Then, just as the crew returned with the parts, Mother Nature finally figured out that there was this big, beautiful balloon just sitting peacefully on the ground. She started to play with it with wind gusts, just like a cat does with a mouse. It was quite a sight to see everyone running around under the balloon trying to keep it from hitting the rough abrasive surface of the old runway. Unfortunately, one particularly strong gust caused it to graze the runway and tore two large holes in the side of the balloon. We taped the holes shut in the hope that it would hold throughout the flight, then launched it during a brief lull in the wind.

The balloon glided across the runway and the bottom payload promptly snagged on what

Photo A. The launch crew prepares the ATV telemetry and tank experiment for liftoff as the balloon is inflated. (Photo by Gene Marcus W3PM.)

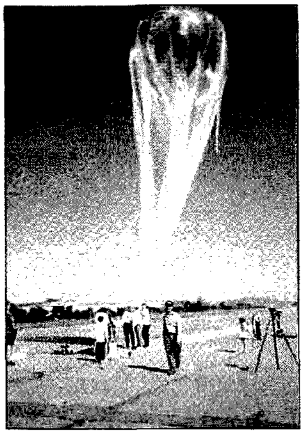

***Photo B.** The inflated Raven balloon stands nearly 40 feet tall. (Photo by Gene Marcus W3PM.)*

appeared to be a power line near the edge of the runway (see **Photo C**). There it was 20 feet up with the balloon sailing out like a kite. Fortunately, this turned out to be an unpowered audio line to some loudspeakers, so I got a long pole out of my car and was able to hook the radar reflector and drag the whole thing off the line. Ed KE4ROC grabbed hold of the payload, ran forward and gave it a big push. Everyone cheered and yelled when everything finally headed off smoothly on its way to the stratosphere after narrowing missing another set of real power lines. When we played back our videotape recording of the payload's point of view, it was quite entertaining to hear and watch everyone running around like crazy under the payload as we tried to free it from the line.

Elevator ride to space

The payload rose upward at a very leisurely 620 feet per minute. The video image was very stable, with absolutely *no* twisting or turning of the payload. Those zero-pressure balloons are nice! It was just like taking an elevator to the edge of space. Since it was a very clear day, the TV camera view of downtown Huntsville and the surrounding suburbs was fantastic. The APRS telemetry worked great and everything was operating smoothly except that telemetry from the pressure and temperature sensors inside of the nitrous oxide fuel tank was intermittent. At 39,000 feet we noticed that the balloon was starting to descend slowly (around 500 feet/minute). Apparently the taped-up holes had sprung leaks and were slowly letting the helium out.

Unidentified floating object

Since the payload was descending so slowly, we decided not to fire the cutdown mechanism to allow the system to fly farther into Georgia and land it closer to the Atlanta area foxhunters who were preparing to chase the payload.

Ralph Fowler N4NEQ organized a chase team to track down the payload. He had an APRS system in his car and we could not only track the balloon's position on our ground station back in Huntsville, but we could track his chase vehicle closing in on the payload as well.

After traveling 108 miles from the launch site, the balloon landed at 1:59 p.m. in a kudzu patch behind the back yard of a house southwest of Dallas, Georgia.

The owner of the house was washing dishes and saw the payload land in a field behind her yard. She thought that a UFO had landed and called the TV and radio stations in the area to report the sighting. She turned on her scanner to see if anyone else had reported the UFO, actually ran across the chase crew on 2 meters—and realized that aliens *weren't* invading Georgia.

The payload survived the landing in good shape and was handed over to Robert KE4GNN, one of our group, who had chased after the balloon from Alabama.

Post-flight results

We learned a lot about flying large balloons and received enough telemetry data to consider the flight to be a success. A balloon flight of this size requires lots of planning and coordination with the FAA. Launch permission needs to be received in advance and we were in constant contact via cell phones to both the local airport's tower and the regional FAA center. They were able to track the balloon system on their radar screens; apparently our radar reflector worked just fine (the reflector is available from Kaymont, 800-644-6459).

For more info about the balloon flight (complete with photos and charts) and details about the telemetry system, check out my home page at the following Internet web site:

http://fly.hiwaay.net/~bbrown/

This page also contains many links for balloon information and other groups.

***Photo C.** The balloon is shown attached to our telephone pole test facility to allow for a photo opportunity and final system testing. Attaching the payload to the phone line requires pinpoint accuracy during the initial launch phase. (I work for the government, so I can put a positive spin on just about any disaster!) (Photo by Gene Marcus W3PM.)*

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

As I write this column, autumn has just begun, but our much-celebrated *Hagerstown Almanac*, published here in Maryland, says that this will be a cold, cold winter. If that's the case, some of the items covered this month should give some of us something to do while the snow melts. Now, with this magazine hailing from New Hampshire, and my living in Maryland, those of you with balmy December weather can just hold your peace.

"Some of the items covered this month should give some of us something to do while the snow melts."

Software for the Kaypro?

From up in New Hampshire I received a letter from Mike Murphy WB2UID, who says, "I have not been exposed to RTTY yet. My station plans are fairly simple, with a Heath Marauder and a Collins R-390A and SSB converter. The Heath is massive and has 100% duty cycle capability; it should work great. I like the idea of using my PC and some kind of filter/adapter circuit to do RTTY or AMTOR.

"I have an old Kaypro 2 (King of the CPM Z-80s?) with dual floppy drives under my workbench at home. Is this thing still useful as a RTTY or CW terminal? I fired it up and it runs WordStar! It is fully metal-shielded, sort of portable, and looks like it would make a nice rig to build a converter into—lots of space inside. Any chance that any CPM software still exists for the Kaypro?"

Well, Mike, there is, and then, again, there may not be. I did a search of available archives and while I turned up a bit of CPM software still around, only one program seemed to be applicable to your situation, a program called RTTY2.LBR. This is a "library" file, a precursor of today's archived or zipped file, that appears to contain RTTY routines for CPM. I have no way of extracting or looking at these files, so I pass along this information for what it is worth. Along with sending you the file, I pass along the information that other CPM files may be found at the Oakland University Archives, on the World Wide Web at http://oak.oakland.edu/oak/cpm/hamradio-pre.html. The files are also on the Oakland FTP site if that is more convenient for you. Additionally, I will have a link to the file on the Download Page of the RTTY Loop Home Page; see the address at the end of this column. Let me know if this file is useful to you, and how you do with the CPM efforts.

New DOS program

After CPM came DOS, of course, so, logically, we should take a look at a new DOS program. Well, you have got to see the new HamComm, version 3.1. This little gem, written by W.F. Schroeder DL5YEC, runs under DOS rather than Windows© 3.x, 95, or NT; or OS/2. It supports reception and transmission of radioteletype (RTTY), AMTOR ARQ/FEC, SITOR A/B, NAVTEX and Morse code (CW) signals. A decoder for SHIP and SYNOP reports from weather stations is also included. PACTOR decoding is available with the registered version. It does not require a RTTY converter, not even a modem chip. The audio output of the transceiver is connected to the serial port of any PC/XT/AT compatible computer through a very simple, low-cost interface. Only one IC is needed (Op-Amp TL071 or similar) and a few diodes, capacitors and resistors. Whether or not this would work with simple computer modems such as the CP-1, I do not know.

For transmission, a tone signal is available at the COM port which can be connected to the microphone input of the transceiver through a passive RC filter. Audio frequency decoding and serial/parallel conversion are all done in software.

HamComm will automatically detect the type of video adapter in use. MDA, CGA, EGA, VGA and Hercules are supported. All graphics routines are written in assembler for speed. No attempt has been made to avoid screen flicker (snow) on cheap CGAs.

HamComm may work to some degree on XT machines, but the graphics displays of the input signal are more fun to watch on an AT-class computer. Nearly all of the functions can also be controlled by using a mouse. A hard disk is recommended but not required. All texts are written in English, and the online help system includes the schematics for the interface circuit. There are also predefined standard phrases, a QTH distance/direction calculator and a callsign decoder. Currently about 370 kbyte of free RAM is required. The interface schematics are included in the online help texts and there is also a section on troubleshooting in case of hardware problems.

HamComm 3.1 is shareware, with a $30 payment due after a 30-day evaluation period. It is an excellent program, with a good track record in previous incarnations, and many "RTTY Loop" readers have used the program with good results.

You can obtain HamComm on the RTTY Loop Download page, as well as in the RTTY Loop Software Collection Disk #13. Details for obtaining this disk are at the end of this column.

Windows software

Windows users, we have not forgotten you. Gary Johnson KF7XP has just released an updated version of his XPWare for Windows Version 1.1.1. This new update supports AEA, Kantronics (KPC-3, KPC-9612 and KAM), SCS (PTC, PTC-Plus and PTC-II), PacComm (PTC and PTC-II) and Hal P38, PCI4000M and DSP-4100 multimode controllers. It allows transceiver control (with appropriate interface) for Kenwood, Icom and Yaesu (FT-767, FT-840, FT-890, FT-900, FT-990, FT-1000 and FT-1000MP). It supports DX cluster spotting, voice announcement on connects and DX spots, ANSI and Bit map graphics, one-key brag files and test. Callbook interface (SAM, QRZ!, Buckmaster and Radio Amateur Callbook), binary file transfers for Clover, GTOR, packet (YAPP) and PACTOR. The program can run one or two controllers at a time (may be different types and brands)—and much much more. Registration cost is $80; upgrade cost for users of XPWare DOS program is $45.

With one program able to do so much, this affordable program can be "test driven" by downloading from either the RTTY Loop Download Page or Gary's web site at: http://www.indirect.com/user/gjohnson . Gary's controller-specific versions under DOS have been fabulous; this one looks to be even better. Take a look if you are hunting for a flexible program to interface one of the supported devices.

For those who came in late, the Software Collection referred to above is a 13-disk assembly of programs of interest to amateurs on radioteletype. Each disk collection may be obtained by sending a blank 3.5" HD disk, a self-addressed, stamped mailer to return the disk to you, and $2 in US funds per disk to the address at the top of this column. A listing of the contents of each disk can be sent to you for a self-addressed, stamped envelope sent to the same address. Alternatively, you may find the complete list, and some programs, on the RTTY Loop Home Page at http://www2.ari.net/ajr/rtty/, where past columns, programs, and other trivia are available, along with links to other interesting sites on the World Wide Web. Let me know what you are thinking, via mail, or via E-mail at: ajr@ari.net, or MarcWA3AJR on AOL, or 75036,2501 on CompuServe. I look forward to hearing from you. See you in '97!

Saving the Amateur Radio Spectrum

A case supporting amateur licensing fees.

Charles M. Seay, Sr. KN4HL
106 South Main Street
Dickson TN 37055

The amateur radio bands are under attack again, especially the 2 meter band and the 440 MHz band by LEO (low earth orbit) companies needing frequency space for new services. The need for more radio spectrum will accelerate in the future with the development of more electronic gadgets. What better place to look for more spectrum than the amateur radio bands?

Why should our bands be such a fertile area for commercial expansion? Because they are not a revenue-producing source for the federal government. The FCC and Congress have seen the enormous revenues that can be obtained from radio spectrum auctions. The more demand generated for radio frequency spectrum, the more valuable our bands will become.

Even though there are over 600,000 licensed amateur radio operators in the United States, these numbers are not significant enough to be politically powerful. Political power is based on numbers. The amateur radio community just doesn't have the numbers to protect its interests, either with the FCC or with the final authority, Congress.

The American Radio Relay League membership represents only a small portion of the licensed amateurs in this country. They are, however, the only game in town when it comes to representing the amateur community. Members are paying over 30 dollars a year for a magazine and no political clout when the final votes are counted. As an example, I direct your attention to the bill introduced by former Tennessee Congressman Jim Cooper, which was designed to protect amateurs from the loss of more amateur spectrum. Even with all its urging, the ARRL could not muster the support of enough representatives and senators to get this bill passed into law. Why? There was no economic incentive for members of Congress to pass such a bill.

"If you can afford a rig, you can afford a license fee."

Have you ever asked yourself why people and corporations make such big contributions to politicians running for office and their political parties? Or why groups and corporations are supporting thousands of lobbyists in a manner you wish you could afford? It is to have access to the powers that could control the economic destiny of that contributor. I can assure you that the presidents and CEOs of communications companies have more access and input to the decision-making process of the FCC and the Congress than the political arm of the ARRL. It's not that the presidents and CEOs are nicer than the president of the ARRL, it's a matter of money.

It's time that amateurs get their heads out of "OZ"; Dorothy and Toto do not exist. Your ability to enjoy the great hobby of amateur radio will come down to the U. S. Dollar. It will involve a decision on each of our parts to pay for enjoying our hobby.

What, *pay* for my God-Given Right to use the amateur radio spectrum? Yes, indeed. If you play golf, swim, hunt, fish, or ski, you pay a fee each year for a license, or greens fee, or a lift ticket. Why should amateur radio be given a free lunch? The bottom line is—we shouldn't.

I have heard the howls that we amateurs should not be charged a license fee because we provide a public service. This is true to a small extent. The fact is that

amateurs, as a group, don't do enough public service to justify the free spectrum. You've also heard that license fees would make the hobby unaffordable to some. Get real, pal. If you've bought any amateur gear in the past few years, you know that we are in an expensive hobby. If you can afford a rig, you can afford a license fee.

I think that a $50 fee for a five-year license would not be out of proportion with the other expenses we incur with our hobby. Small fees for changes of addresses and callsigns, and license exams would be appropriate. It is a matter of economic fact that if we want to play, we are going to have to pay our fair share.

Under the burden of this country's budget deficit, politicians are looking at every conceivable source for funds to support their pet projects. We amateurs can sit around, then bawl and bellow as our allotted radio spectrum is sold out from under us, or we can make our part of the radio spectrum economically justify its existence.

This proposal is not one-sided. With the payment of license fees, the amateur community has every right to expect that the FCC will do a better job of policing the amateur radio spectrum. It is time the FCC enforced their own rules, something they've been neglecting for several years. One of the reasons for this neglect is the lack of funding by Congress for this police action.

It all comes down to money. We complain to the FCC about the garbage on our bands and nothing is done because there is no money. We complain about the loss of our bands to commercial interests and we lose radio spectrum because there is no economic justification for our space. It's time we paid the piper—the dance is just about over.

Note: The above will, I hope, be a dose of reality salts for hams who are ignorant of how our government works. But $10 a year for a ticket is insignificant. To have any hope of clout against Motorola, G.E., Matsushita, Sony, Hitachi, Toshiba, et al., we're talking more like $100 a year. And that, if we can hold on to a half million hams, would still only be $50,000,000 a year—while the FCC is bringing in billions with their spectrum auctions. If we had to pay for our licenses we might have more respect and less trashing of our hobby on the air. We could also expect more help from the FCC with our garbage collecting. Most people just don't respect anything that's free! ... Wayne.

LED Checker Plus

Make it even more useful.

Tom Thompson
Box 49481
Blaine MN 55449

If you have already built the LED Checker (see *73*, January 1989, p. 61), then I have a simple change that will turn it into an even more versatile bench tool.

Several new options are available with the Plus model, such as in-circuit testing of LEDs including displays, polarity testing and identification of diodes, and an external DVM connection for forward voltage measurement, which is helpful in determining if a diode is silicon, germanium or a Schottky type.

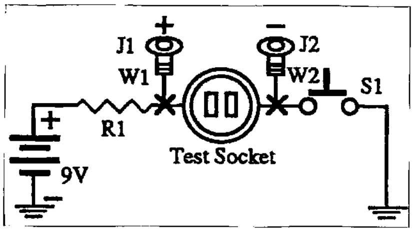

Fig. 2. The improved LED Checker Plus allows measurement of forward voltage drop, as well as in-circuit tests.

The original circuit

First, familiarize yourself with the original circuit (**Fig. 1**) The basic circuit is the same, except without the two jacks for external test leads added in this enhancement.

The operation is simple! Insert the LED into the test socket and press S1. If the LED is on, it is good. If it's not on, turn it 180 degrees and put it back into the test socket. Press S1 and the LED should be on. If not, it is defective.

The modification

See **Fig. 2**. The "Plus" model merely has wires W1 and W2 added to the original circuit directly to the "+" and "-" terminals of the test socket. These wires are then soldered to J1 and J2, a pair of five-way binding posts (RS-274-662). The red binding post should be connected to the "+" and the black to the "-." You can mount the binding posts wherever you want, but the industry standard is 3/4" between centers. Or you can also use banana jacks, which are less expensive.

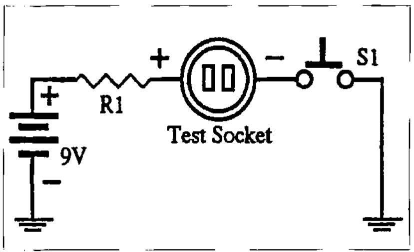

Fig. 1. The original LED Checker circuit.

In-circuit LED testing

See **Fig. 3**. For in-circuit LED testing you connect your clip leads "+" and "-," then clip them to the two LED leads and press S1. If the LED goes on then it is good. If it doesn't then you reverse the leads and press S1 again. If the LED is still not on then it is bad.

In some cases, if several LEDs are in parallel or there is too much current being drawn by the circuitry then you may have to unsolder one of the leads to isolate it from the rest of the circuitry.

Diode forward voltage testing

This testing is usually done to determine the voltage drop across the diode while it is on. To check diode forward voltage, connect your DVM to the Checker, red to "+" and black to "-." Set the DVM to DC volts on the 2 or

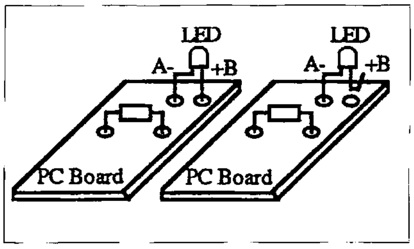

Fig. 3. The LED Checker Plus can be used in-circuit.

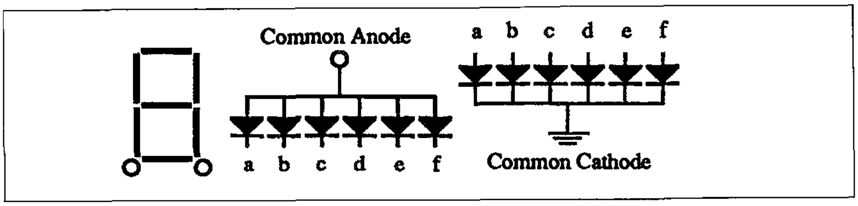

Fig. 4. Seven-segment displays are available in either common anode or common cathode configuration.

20 volt range (this will vary with different models of voltmeters). Put the diode into the socket and press S1. If the diode is in correctly the voltage measurement will appear on the display. If not, reverse the diode and try again. Remember, you must press S1 each time you test. A silicon diode will have a voltage drop of about 0.7V (1N914); germanium will be about 0.4V (1N34); Schottky 0.3-0.4 (1N5818); and any LEDs 1.4-2.4V. Your tester pulls about 10 mA, so if you have a data book you can check the forward voltage at 10 mA to determine what voltage to expect for a given diode type.

> ***"I checked a two-digit display on which I had no information and had all the pins identified in five minutes!"***

Seven-segment display testing

In testing seven-segment displays you'll find one of two types: common anode or common cathode (see **Fig. 4**). The key here is to locate the common lead. If you are working from a schematic then look for a "+" connection for a common anode and a ground "-" connection for a common cathode.

If you don't have a data book you'll have to guess, but that's easy. Common anode displays usually use pins 3 and 14; common cathode displays usually use pins 1 and 6. This is a good place to start.

If your deduction indicates that the display has a common anode then connect the "+" lead to the common pin or the lead you suspect to be common, and attach the "-" lead to any of the remaining pins. Press S1. If no segments turn on move the "+" lead to each lead, pressing S1 after each connection. Once you get a segment to turn on you have found the common lead. Keep the "+" connected where it is and move the negative lead around until all the individual segments come on one at a time. If you have a common cathode then connect the "-" to the common lead and attach the "+" lead to any of the remaining pins, pressing SI each time. Make some notes to keep track of your progress. Remember, your LED Checker limits the testing current to a safe value so it will not damage a display.

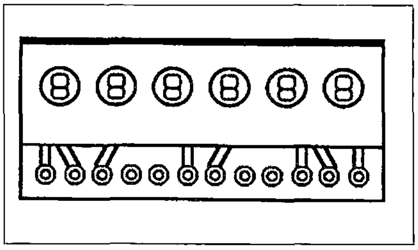

Fig. 5. A typical six-digit multiplexed display.

Multiple-digit display testing

Multiple-digit displays usually have common segments but have separate anodes or cathodes for each digit. You need to find all the digit pins as well as the segments. This is relatively easy and is done by noting what segment is on and what digit position it is located in. Make a drawing as you do the testing. I checked a two-digit display on which I had no information and had all the pins identified in five minutes! More complicated displays, such as that shown in **Fig. 5**, may take 10 to so minutes.

Well, that's about all there is to using the LED Checker Plus. Maybe you can think of some other unique uses and share them with the other readers!

A kit for the basic LED Checker Plus is available for $10.95, plus $2.50 shipping and handling, from Home Net, Box 49481, Blaine MN 55449. It's also available on Home Net BBS @6127559661.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 30. Provide a clear, concise summary of the essential details about your Special Event.

NOV 22–23

OCEAN SPRINGS, MS The West Jackson County ARC, Inc. will present a Hamfest/Swapfest at the Latimer Comm. Center, north of the city of Ocean Springs. Swap and Flea Market tables are $5 each, to be paid in advance. Mail table reservations to *WJCARC, P.O. Box 1822, Ocean Springs MS 39564*. For details, contact *C.F. Kimmerly N5XGI, (601) 826-5811*; or *Mike Gurley KC5QXE, (601) 475-6161, after 5 PM.*

DEC 1

HAZEL PARK, MI The Hazel Park ARC will sponsor their 31st annual Hamfest, 8 AM–2 PM, at Hazel Park H.S., 23400 Hughes St. Free parking. Reservations for eight-foot tables ($14 each) must be received with a check. No reservations by phone. Send payment to *HPARC, Inc. Swap, P.O. Box 368, Hazel Park MI 48030*. Talk-in on 146.640/443.225 DART Rptr. Six-foot tables available at the door for $10; limit one table per customer while they last.

DEC 7

GOLDEN VLLEY, MN The annual Courage Center Handi-Ham Winter Hamfest will be held at the Handi-Ham Headquarters, 3915 Golden Valley Rd., starting with registration at 8:30 AM. There will be a Handi-Ham equip. Auction, Flea Market, Dinner at noon, and Program. Contact *Don Franz WØFIT, 1114 Frank Ave., Albert Lea MN 56007.*

DEC 14

JACKSONVILLE, IL The Central Illinois Winter Superfest, sponsored by Illinois Valley ARC and Jacksonville ARS, will be held 8 AM–2 PM at Turner Jr. H.S., 664 S. Lincoln Ave. Vendor setup at 6 AM. VE Exams at 10 AM, pre-reg. required. Contact *Tim Childers KB9FBI, 773 E. College, Jacksonville IL 62650; Tel. (217) 245-2061*. Talk-in on 146.775(-), and 444.675(+). Advance reservations taken until Nov. 30th. Send SASE and check payable to *Jacksonville ARS c/o Kaye Green KB9KHQ, 27 Ivy Wood Drive, Jacksonville IL 62650.*

LAKE CITY, FL The Columbia ARS will hold its 2nd "Gateway to Florida" Tailgate/Hamfest at Robert B. Harkness Florida Nat'l. Guard Armory, 153rd Engr. Co., Lake Jeffery Rd. Call (904) 755-7969 for details. Talk-in on 145.490 (-), alternate 147.150(+).

SPECIAL EVENT STATIONS

DEC 6–DEC 7

MESA, AZ East Valley Amateur Radio Group, WA7USA, will commemorate the Battleship USS Arizona, from 1500Z–2400Z on 14.240 MHz and 21.340 MHz. Stations contacted may request a certificate by sending a QSL card and a 9" x 12" SASE to *EVARG, 3264 E. Carol Ave., Mesa AZ 85204-3245*

DEC 14

CHRISTMAS, AZ The TriCity ARC will operate from Christmas AZ in celebration of the Christmas season. Phone operations will take place from 1500 UTC–2100 UTC, on 7.225 MHz(+) and 14.240 MHz(+). Send QSL and SASE to the event callsign's *Callbook* address. Callsign to be announced.

DEC 14–DEC 15

NAZARETH, PA The Delaware-Lehigh ARC will operate W3OK (or possibly WX3MAS) as the Christmas Cities' Special Event Station. The station will be on the air 1400Z–0200Z from the twin Christmas cities of Nazareth, PA, and Bethlehem, PA. Freq.: 3.965, 7.265, 14.265, 21.365, and 28.365. For a certificate, send QSL and a 9" x 12" SASE to *DLARC, RR 4, Greystone Building, Nazareth PA 18064 USA.*

DEC 14–26

BELEN, NM The Valencia County ARA will operate KC5OUR 1800Z Dec. 14th–0000Z Dec. 26th to celebrate Bethlehem. (Belen is the Spanish word for Bethlehem.) A QSL card will be sent to all who provide an SASE. QSL to *KC5OUR, 93 Nash St., Belen NM 87002 USA.*

JAN 1997

GISBORNE, NEW ZEALAND The amateur fraternity is fast heading into a new century, with the year 2000 rapidly approaching. To acknowledge this event, the Gisborne ARC (Branch 11, NZART) will sponsor an annual international award, using the callsign ZL2000, until the year 2000. The award is open to all amateur radio operators and SWLs. To achieve an annual award, only one contact is required with a ZL2000 station during the month of January each year, until the year 2000. A special complimentary award will be issued to all stations that contact a ZL2000 station for four out of the possible five years, up to and including the year 2000. The fee for the annual award in New Zealand is $5, for Australia $5, and for the rest of the world US $10. Contact Gisborne 2000 Award, P.O. Box 1017, Gisborne, 3815, New Zealand.

What piece of ham gear would you most like to get for Christmas?

QRP

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

December already? Yes, it's true, 1996 is coming to an end. I sure hope the year was better for you than for me. Whatever I touched or did seemed to come apart this year. Let's hope 1997 is better.

Aside from the lack of sunspots, operating QRP has been an exciting hobby within ham radio. We've seen all sorts of new gear tailor-made for QRPers. Some of the gear is getting rather fancy compared to what we have become accustomed to.

Small thin film solar modules for QRP use

I've had several letters asking about soldering wires to thin film solar panels. These amorphous silicon panels have been turning up at surplus stores around the country. Some of the prices have been very attractive as well—but the downside is that there are no wires connected to the modules. In fact, when a thin film module is made, it can easily be cut up into even smaller modules, with only a glass cutter. This is what happens if the buyer gets a shipment of large modules. If the guy who does the cutting keeps the same amount of cells, the modules will always be the same voltage, but will generate small currents. The amount of current is dependent upon the physical size of the module.

Now, to make matters even worse, you just can't solder wires onto the glass substrate of a thin film module! In late August, I spent a week at Solarex in Frederick, MD. One of the first questions I asked was, "How do you solder wires onto the back of a thin film module?" Their answer? You don't. Here's the whys and the why nots of soldering to a thin film solar module.

The backside of the thin film module is made out of a substrate of either tin oxide or aluminum oxide. Both are deposited on the glass by flashing the material (let's say aluminum) onto the glass or in a plasma chamber. The coating is only several microns thick. So, with a material so thin, there's not much to hold onto.

Since we don't know what the substrate is made of we can try one (or both) of two methods. First, a silver solder, with a high content of silver, should work with the tin oxide substrate. The silver solder must have a very low melting point. If the melting point is too high, the tin oxide is burned away before the solder has a chance to stick.

If the silver solder did not work, then the substrate must be aluminum oxide. We can then try some aluminum solder. Right off hand, I don't know of a source for this stuff. The aluminum solder must also have a low melting point. You'll also need an adjustable soldering iron; you must lower the operating temperature of the tip to prevent burning off the oxide.

"A thin film module about the size of this magazine will produce about 3-5 watts under a full sun."

A cheap and dirty way to make your soldering iron so you can vary the tip's temperature is to use a lamp dimmer. You can get these from any home improvement center.

If, by chance, you manage to get the wires soldered, then you must protect the connections. Remember, there is not enough material for a strong joint. A coating of RTV or hot melt glue will be needed to secure the connections. With a lot of luck, you may be able to make connections to the backside of a thin film module.

If you do, then apply a film of RTV around the edge of the glass. Water will seep up into the active material if you don't. Solarex prevents this by using a laser to burn off a strip of active material all along the edge of the thin film module. This effectively isolates the active material from the glass edge.

A thin film module about the size of this magazine will produce about 3-5 watts under a full sun; combining this module with a small gelled lead acid battery will power most of the single-band QRP rigs on the market. See my Micro "M" portable charge controller in the September issue of *QST* if you want a charge controller for your portable station.

"This power supply will produce 12 volts at 1.5 amps, and it costs only six bucks."

Low-priced power supplies

I'd guess most QRPers have access to several sources of power for their rigs. If not, and you don't want to home-brew one, I have found several that will power a QRP rig. The best part is the price. These power supplies are surplus and were made to power laptop computers.

Many of these supplies are of the switching type. I'm not sure if the switching noise would get inside a direct conversion rig or not. Perhaps, but you should have no trouble running a superhet rig with one.

Hosfelt Electronics (800-524-6464) has several units that look good. One in particular is a tiny guy who measures only 6 by 2 inches. It will produce 12 volts at 1.5 amps. Best of all, it's only six bucks. Its stock number is 56-448. For $10 you can get one that produces 18 volts at 1.4 amps (40-140), ideal for battery charging. By adding on an external three-leg regulator you would have the basics for an adjustable power supply.

If the switching noise is getting into your rig, then Hosfelt has a linear supply that produces 12 volts at 3.4 amps (40-176) for $25.

DX news for QRP ARCI

Dick GØBPS has resigned as the UK rep for the QRP ARCI. What does this mean to you? If you live outside the USA or Canada you must now send your renewal fees directly to me and not to Dick. It also means we have to rethink the way you send your funds.

First, the QRP ARCI does not accept credit cards. Second, I know the price of getting an international money order often exceeds the price of the dues. So what's a ham to do? Send cash.

Yup! I know, I've said it, they've said it, even your mother said it: Do not send cash in the mail. However, you can send cash if you follow these simple steps.

First, do not put my callsign or your callsign on the letter. You want the letter to look as generic as possible. Second, do not address the letter to QRP ARCI. Address the letter to me. Do *not* send the letter certified or requesting a signed return receipt. Remember, you want the letter to look just like one you would send to dear old Mom. Are you going to send *her* one by certified mail? I think not! If you want an acknowledgment of your letter and money, enclose a mailing label and first class unit of postage inside your letter. IRCs are fine if you have some lying about.

Wrap your money in either carbon paper or aluminum foil. This prevents prying eyes from seeing the money through the envelope. If possible, use large bills instead of singles or fives. A twenty and a five will mail cheaper than five fives. Some of the postage rates are incredible, one reason why the QRP ARCI has raised the DX dues to $25 a year for airmail delivery.

For all members of the QRP ARCI, I've moved. The new address is:

QRP ARCI
P.O. BOX 508
Massillon OH 44646

VHF and Above Operation

C. L. Houghton WB6IGP
San Diego Microwave Group
6345 Badger Lake Ave
San Diego CA 92119
Internet: clhough@aol.com

Now that we have built several converters and covered them in quite a bit of detail, I am ready to put the cart before the horse, so to speak, and discuss IF system operation. I admit that I did not plan to cover this aspect of microwave operation because it just didn't *occur* to me before.

I have been an amateur for a good number of years and have accumulated quite a pile of material that I draw upon to construct projects. I've been known to take an existing complete radio which has fallen into disuse and construct something inside it, changing the main function completely.

Back then, when radios were not quite as small as today's devices, there was plenty of room to construct adjuncts into a radio case, changing the rig's operational point of view while retaining the beauty of the original product. Take, for example, one of my early converters, constructed to replace my 2 meter transmitter and separate receiving converter. At that time I was using a tube-type transmitter for 2 meters that was crystal-controlled on 145.5 MHz (AM) and ran with three 6AQ5 multiplier tubes and a single 6C4 oscillator. You might point out that the 6AQ5 was an audio amplifier. I agree, but it worked. The receive converter was a premium crystal-controlled downconverter from 144 MHz to 14 MHz for the IF frequency.

"Sometimes you eat the bear—and sometimes the bear eats you."

The main shack VHF receiver was a National NC-303, about the size of an apple box. The plan was to take a recent surplus Heathkit 20 meter single-band transceiver and convert it to 2 meters. I was able to pick it up for minimal cash output as parts were missing and it was unfinished. Well, to make a long story short, I removed the high power parts and finished the transceiver (20 meter), then mounted the 144 MHz converter and a transmitter from a salvaged Gonset transmitter for 2 meters. This new transmitter, though still crystal-controlled, used a 2E26 final and put out 5 watts (AM).

All this was stuffed into the Heathkit 20 meter monobander. This project gave me a deluxe 2 meter station (and the beginnings of 2 meter SSB operation), using mostly scrounged junk. This was my start with VHF and the late '60s/early '70s construction. My tool collection included a round rasp file and rattail file to round out holes drilled on the back porch to hold tube sockets, meters and such. Quite a humble start.

I think back to those days and the enjoyment and struggle that I went through to put together what I consider quite easy today. How much time I could have saved if I'd had a better grasp of technical details and math applications! Today, with a computer at my home and model simulation at my fingertips for circuits that were bench-top struggles then, I can make vast improvements, even using a slow 286 IBM mainframe.

Yes, I still have a 286, and even some old CPM machines that still function. They sit next to my 486 super-duper speedster. I guess it's always speed and performance for the assistance of man, but I still retain the slower, more comfortable old shirt and blown-out tennies for when the mood strikes.

Well, there you have some of my deep dark projects of years gone by. The ideas still have a familiar ring; only the tune has changed a bit. Today we build converters into cases that seem to suit the material and retain the IF system outside the environment of the converter. This is because the IF system is in plentiful supply due to the very heavy use of 2 meters and multimode rigs.

Sure, some of these rigs are old by today's standards of CTCSS tones and two or more synthesized VFO oscillators or programmed frequency entry. Don't be fooled by the expensive price tags on the newest rigs and let that prevent you from using a simpler version of the same radio. Look in the used market for a suitable unit that might not have all the newest bells and whistles. Used equipment stores and flea markets may provide an IF system that can be applied to microwave converter use.

A bargain can be had, especially if you purchase a blown or defective radio that might have a high power transistor amplifier stage destroyed. Don't tell the person you are haggling with that this is just what you desire, as you don't need a power amplifier in your IF system radio. (*My Rule #1: I disable all power amp stages as it is not a requirement in converter use.*) A low power output in the 100 milliwatt range is ideal as you still need to reduce it to +10 dBm from this power level.

At the 100 milliwatt power range (100 mW) we still need a small value of attenuation to reduce power for input to a microwave mixer. While there are mixers that will handle 100 mW +20 dBm of power, most prefer +10 dBm. Converting power in watts to dBm might seem a little intimidating at first but it is quite easy if you know a couple rules of power. The main rule is that every power change in watts that doubles or divides by two results in a 3 dB change in power. A 10 watt radio output power is the same as stating your radio outputs power of +40 dBm; 10 watts and +40 dBm are the same power level, just stated differently. Now subtract 3 dB from the +40 dBm level: -3 dB = +37 dBm = 5 watts of power. Keep going and the following is true: +34 dB = 2.5 watts, +31 dB = 1.25 watts, +30 = 1 watt, +27 = .5 watt and +20 = .1 watt or 100 milliwatts.

Why use a 30 dB attenuator to reduce a 10 watt transceiver power to +10 dBm for input to a mixer? Yes, it can be done, but you're wasting a lot of battery power in portable operation and giving it up as heat with no useful application. The same transmitter with the power stage removed or disabled can be put to much better use with less drain on portable batteries.

Rule #2: My used 2 meter transceiver doesn't have any repeater tone control built into the radio. Well, this is a benefit again because the CTCSS tone and repeater subaudible tones are not used on the microwave bands. Details like this make the radio somewhat high on the priority list to be replaced from a repeater operator's point of view. Many amateurs will take this older equipment's used value in trade towards the purchase of newer transceivers. This is where the microwave land sharks come into play, trying to locate these older transceivers, especially the units capable of SSB operation.

Where can you find these transceivers capable of SSB operation? Well, try your local flea market and ham club swap meets. Do what the big guys do—advertise. Use a small file card on your club bulletin board or at your local ham radio store's courtesy bulletin board. Mention your wants during various net activities on the air. You will never know how successful you can be until you try some of these methods.

My successful finds

Some of the rigs that meet the multimode 2 meter plan of attack include the Santec LS-202, ICOM IC-202, IC-245, IC-260 and Yaesu FT-480. All of these radios are 2 meter capable and have SSB operation, and some have FM and CW. The LS-202 is a handie-talkie and a multimode miniature transceiver with SSB, upper and lower SSB, CW, and FM, in a pack with 8AA batteries. Its detriment is that the knobs are quite small, but it performs well in any mode of operation.

I obtained this radio as a basket case junker with no power transistor, driver, and a busted audio potentiometer, and it arrived in 10 pieces. It wasn't *that* bad as most of the wiring was still in place because it had been disassembled for repairs that were never made. It sat in someone's junk box for quite a few years until I asked the question, "Got any multimode rigs?" It was brought out and I bought it. The seller would have never thought about selling it, and was almost not going to sell it because it was in such bad shape. But I insisted that I was willing to take it without any guarantees. That satisfied the seller, relieving him of any obligation. That was some six years ago and since then that radio has operated well, with only three other trouble/repair scenarios. These were completed and it's still working today as my smallest portable multimode radio.

You might think me crazy because of some of my other choices. I obtained an IC-245, with an SSB/CW adapter, that had driven its owner nuts with drifting VFOs and intermittent operation. In a chance encounter he offered it to me for $5, so he could be rid of the dreadful device.

Well, my first ICOM radio was an IC-211 that had similar problems, and this IC-245 was a mobile version of that same radio. The circuitry problems that I troubleshot over several years on the IC-211 related to the plated rivets used to connect the top and bottom PC board traces. They became flaky in the conductivity department with time, even with soldering, and would go open. (The fix put a wire through the rivet and bond to top and bottom trace of the PC board.) Having spent a bunch of time to repair the IC-211 (a repair job approaching an act of love), you could say I got a real education on very early ICOM radios. I applied the same fix to the IC-245 that I had used for the IC-211.

"Don't attempt to repair an expensive piece of equipment before doing your homework."

Standing now on familiar ground (the IC-211 and the IC-245 synthesizer are exactly the same), I grabbed the file with my repair notes on where all the solder rivets were on the synthesizer chassis, and other shortcut fixes I used in repairing the IC-211, and installed the standard fix to the IC-245. I put the covers back on and applied power, and I lucked out! It worked right off the bat. It has one related idiosyncrasy that I am still trying to fix but that is intermittent—it only happens about twice a year.

Would everyone tackle such a project? Well, we will never know the answer to that one, but if you should choose to attempt such a task it can only reap rewards. This reward might only be increased technical awareness—but be patient and don't spend a lot of money to only tempt fate. Be prudent and improve your troubleshooting and repair skills using inexpensive items to work on at first. Don't attempt to repair an expensive piece of equipment before doing your homework. Build up to the experience level needed to work on a complex piece of equipment. You'll improve with time.

What was the disposition with the Yaesu FT-480 multimode rig? It was purchased at a swap meet from an unfamiliar person and was advertised to be in good shape and tested. Well, the price dropped when there was no mike or power cord to be had, nor any manual. This to me meant the radio was in very dubious condition and unchecked. With my hand still on the unit, and alert for other bargain-hunters, haggling commenced. Soon a mutual price was worked out and it was mine.

I took it home and made a power cord and mike, turned it on, and the receiver was dead. No audio at all, with or without the squelch ... nothing. The frequency dial responded OK so I tried transmit in low power and it worked well and on frequency. Looking at the chassis, which had a very tightly-packed component high-density construction, I opted to order the manual and schematic before beginning surgery. The manual was very reasonable—$20—and available from Yaesu (my hat's off to Yaesu and their excellent service department).

I received the service manual and in the troubleshooting guide there was my exact trouble condition as trouble #1. The fix? Replace a dirty miniature relay contact used to switch a DC voltage between the transmit and receive control circuits. Three minutes to fix the radio and 10 minutes to put the covers back on. It had been a simple problem, but a hard one to locate without the manual. Sometimes you eat the bear—and sometimes the bear eats you.

In retrospect, I guess I got eaten by the bear in my dealings with my IC-211 repair job and pulled off a reverse on the LS-202 and the IC-245. It takes persistence and application and the willingness to overcome repair obstacles to extract a bargain from surplus or swap meet sources. Have I ever received perfect equipment from swap meet sources? Absolutely! An IC-260 multimode 2 meter rig in perfect shape. Don't cast doubt on everything, just examine it

carefully instead of letting emotion run the purchase.

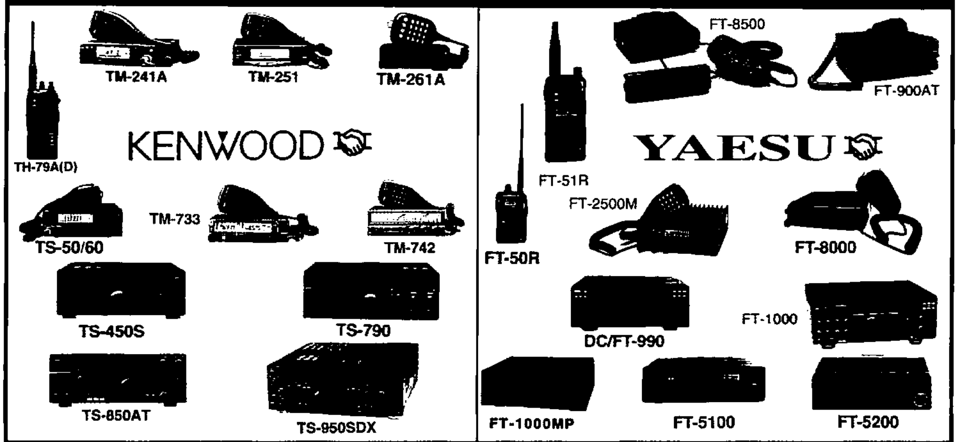
The 2 meter IF system

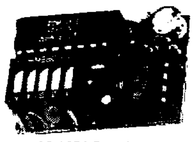
What is the best attribute of the radios I have described so far, and what improvements would I suggest? Well, by using a 2 meter IF system for your microwave converter you have the ability to utilize its different modes of operation: SSB, CW, and narrowband FM. Additionally, you have an accurate frequency dial to amble about your converted microwave frequency, usually the selected converter frequency plus 4 MHz of tuning range.

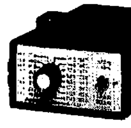
If you were operating at 5760 MHz and using a 144 MHz IF then you can span the 5760 MHz to 5764 MHz tuning range on the IF system at 2 meters via the converter. This gives you a great receiving and transmitting system by allowing the IF system to basically run the show. Allowing for transmitter power reduction or disabling the power stage is a must for converter use. Also, a point to consider is the frequency control knob on most of these transceivers I have described. With the exception of the IC-211, all have detent-type harsh tuning for frequency control of the 2 meter radio.

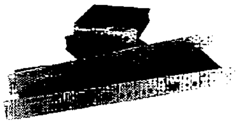
I wish some of the manufacturers would take heed and produce a radio capable of making the transition from a multimode transceiver with power and sensitivity to a low power converter mode device. There should be some means to shut off the power stages and bypass them for low power output, not switched low power. Having a switch that changes power level is not prudent to run switched low power into a microwave converter. While this option will work, it can destroy the converter's low power input mixer and other circuitry if the power switch is accidentally bumped or operated. It is better to have a fixed hard pulled-down low power conversion that will not harm a sensitive expensive microwave mixer.

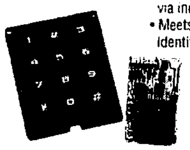
Well, that's it for this month and this year. I hope you and yours have a very Merry Christmas and a Happy New Year. Best 73 Chuck WB6IGP.

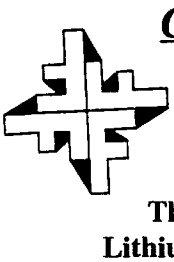












NEW PRODUCTS

Number 84 on your Feedback card

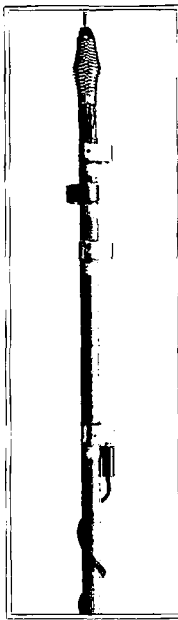
Perfect Stocking Stuffer

Alinco Electronics introduces the DJ-S41T, a handie-talkie transceiver that operates on the 70 cm (440 MHz) band. It's only slightly larger than most pagers, runs on three AA batteries, and it's priced under $150 at most Alinco dealers.

At a price nearly everyone can afford, the DJ-S41T features 21 non-volatile memories, CTCSS encoder, offset capability up to 15.995 MHz, and transmits with a power of 340 milliwatts, more than adequate to hit repeaters or carry on simplex communications over a considerable distance.

The DJ-S41T has a pivoting "swing up" antenna, keeping the radio compact enough to carry in purse or pocket, on a belt like a beeper, or in a kid's backpack; and if you don't have to detach the antenna, you probably won't misplace it. The universal reaction when people try out the DJ-S41T is "How can I get one?" Find out for yourself at your nearest Alinco dealer.

Slimline Mobile Antenna



Palomar Engineers announces a new slimline mobile antenna for the 75, 40, 20, 15, 10, 6 and 2 meter bands. The AN-7's Fiberglas™ base section is four feet long with a spring protected three-foot whip on top. Change bands by selecting taps on the helical base coil. The AN-7 was developed by Antronic, a major South African manufacturer, and has been in use in the South African bush country for years—it is now available in the United States for the first time.

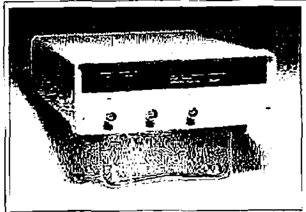
The complete antenna weighs only two pounds and presents a very small wind-loading area. Its discreet size and attractive finish make it suitable for use where other antennas would not be permitted, and it's priced at only $249.95.

For more information, contact Palomar Engineers, P.O. Box 462222, Escondido CA 92029. Telephone 619-747-3343, FAX 619-747-3346, or E-mail 75353.2175@compuserve.com.

Affordable DSP — to Go!

Kenwood's new TS-570D HF transceiver offers the world's first CW Auto Tune feature, which eliminates VFO adjustments during CW operation. The TS-570D also has a Radio Control Program that will be available for operators to design and program multiple radios with custom settings while conventionally saving them to a file for future use.

If you've been waiting for a DSP (Digital Signal Processing) HF radio that'll fit into your budget, check with your authorized Kenwood dealer for details, so you can enjoy the TS-570D, destined to take its place alongside other world-renowned Kenwood rigs like the TS-50S.



Atomic Clock Accuracy

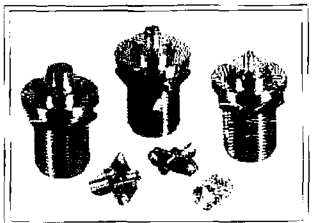
Novatech Instruments, Inc. introduces the Model 2955AR Rubidium Standard with Synthesized Output. It has a direct digital synthesizer output that is 32 bit programmable from 10 Hz to 4 MHz, and fixed outputs of 10 MHz and 1 MHz. The 2955AR contains an Atomic Resonance Rubidium Oscillator and has long-term stability of better than $5x10^{-11}$ per month and short-term stability of better than $0.7x10^{-11}$ in 10 seconds.

There's an EEPROM memory in case of power shutdown, and it's ideal for use in communications system applications since the 2955AR can be set to standard frequencies such as the 1.544 MHz T1 frequency. Of course, it's also perfect for laboratory and ground station use, as a master oscillator, as well as for tests and calibration, and the 2955AR is attractively priced at $4,295. You need one. Yes, you do. Check out the specs on the web site at http://www.eskimo.com/~ntsales, or write Novatech Instruments at 1530 Eastlake Avenue East, Suite 303, Seattle WA 98102.

Sunspot Cycle Got You Down?

Down on the lower HF bands, that is? Bilal Company may have the answer for acreage-challenged hams who want to work the 160 meter band. Many conventional HF antennas require lots of space—but the new Isotron 160C is under 10 feet tall and mounts on a conventional mast. This resonant antenna requires no radials, is tunable and can be set for a preferred portion of the band.

You'll be impressed by the Isotron 160C's transmitting and low-noise receiving performance; and it's only $159.95. For more information about the Isotron antenna line or a free catalog, contact: Bilal Company, 137 Manchester Drive, Florissant CO 80816.



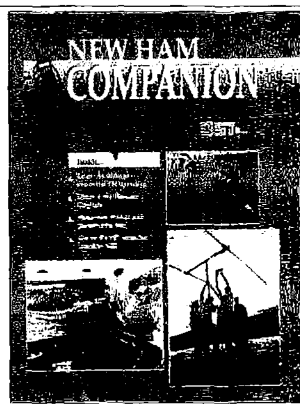
Connectors

RF Connectors has released two series of connectors for semi-rigid cables. Rear-mount N female bulkhead connectors are available to accommodate .086, .141, and .250 cables. SMA plugs, bulkhead jacks and two-hole and four-hole panel mount jacks are available for .086 and .141 cables. Connectors feature Teflon™ insulation, gold contacts, and nickel or gold plating.

The connectors are available from RF Connectors distributors throughout North America. For additional information, specs, and availability, call 800-233-1728 or E-mail: 102061.2261@compuserve.com.

It's Worth It

New Ham Companion from the ARRL. With the League membership growth stagnant, and the only significant growth in the hobby being the no-code licensees, the League has addressed this group with a 64-page booklet (about half of it is ads). It explains how repeaters work, about packet, antennas, satellite contacts, learning the code and low-cost low band QRP. You get your $2 worth.



Spiffy Free Catalog

Time Motion Tools has released its new 172-page catalog of tools—and it's full of cool toys: hand tools, power tools, lighting and magnification tools, all kinds of meters, including the new Fluke 7-300 and other Fluke meters. If you haven't yet got hold of this one, write or call Time Motion Tools, 12778 Brookprinter Place, Poway CA 92064. Phone (800) 779-8170, FAX (800) 779-8171; or visit their web site at http://timemotion.com.

Get More Ladders!

Cable X-Perts, Inc. announces two more ladder line cables—the 300 Ω ladder line cable and the 14ga 450 Ω ladder line cable. These balanced transmission cables provide low loss attenuation across the HF (>30 MHz) bands. Prices start at 100 feet and up—0.13/ft for the 300 Ω version and 0.25/ft for the 14ga 450 Ω version—discounts apply at 500 ft and 1000 ft quantities. For more information and other special offers SASE to: Cable X-Perts, Inc., 416 Diens Dr., Wheeling IL 60090. Phone orders only (800) 828-3340, or E-mail: cxp@netcom.com.

CAT Got Your Code?

Computer Aided Technologies announces the Code 3-Gold, a new VHF and shortwave decoder that uses the best of software detection technology and the latest in miniaturized electronics for the hardware interface.

Systems supplied as standard include packet, BAUDOT, SSTV, NAVTEX, PACTOR, and more. For further information, contact Computer Aided Technologies at P.O. Box 18285, Shreveport LA 71138, or call (318) 687-2555. Internet users can contact the company on the WWW at <http://www.scancat.com>.

It's Like Being There

Pacific-Sierra Research Corporation offers a guided Internet tour of their new HFx software, which provides quick, easy accurate propagation predictions. HFx calculates ionospheric signal strength from 2 to 30 MHz, using an intuitive Graphical User Interface. The central feature is the HFx Interactive Map, which can display the subsolar position, day/night terminator, the great-circle path between transmitter and receiver, major cities, and the high-latitude auroral ovals. Just click the mouse!

It's designed especially to be easy enough for beginners to use, and thorough enough for experts, and it's only $129 postpaid worldwide—check it out at the HFx home page: http://www.psrv.com/hfx. For more information or to order, contact HFx - Dept. 73, Pacific-Sierra Research Corporation, 2901 28th St., Suite 300, Santa Monica CA 90405-2938, USA. Phone (800) 820-4PSR; outside US and Canada (310) 314-2346; FAX (310) 314-2323.

Orchid City's Newest

Orchid City Software has completed the Voyageur v1.1 Radio Database for DOS, a comprehensive suite of database programs for broadcasting radio stations' information gear toward the radio DXer and listener. You want to know what's going on in the DX/SWL world? Here's a list of DX/SWL program schedules. Find any program by the day of the week, time of day, station, etc. You've got a program for writing log reports and printing in a number of formats—type it once and print multi formats. Schedules, frequencies, addresses, radio station slogans—in English, Spanish, Indonesian, French, Portuguese, and more!

The Voyageur v1.1 already contains thousands of records and is completely read/write: it can be updated, changed, or added to easily. To order your copy send $29.95 to Orchid City Software, P.O. Box 18402, West Palm Beach FL 33416. Overseas orders add $10.00 for additional postage.

Radio Bookshop

Great ARRL Books!

AR1086-4 **ARRL Operating Manual** Information on how to make the best use of your station, including interfacing with home computers, OSCAR, UHF-VHF. $22.00

AR4173 **Now You're Talking! All You Need To Get Your First Ham Radio License**–A complete study guide for the Technician and Novice written exam. Practical information every beginner needs is written clearly and simply and in small doses. $19.00

AR4734 **ARRL Antenna Book.** Best and most highly regarded info on antenna fundamentals, transmission lines, design, and construction of wire antennas. $30.00

AR4971 **ARRL Repeater Directory 1996** Over 19,000 listings with digipeaters, bandplans, CTCSS (PL(TM)) tone chart, frequency coordinators, ARRL special service clubs, and beacon listings from 14MHz to 24GHz. $7.00

AR3177 **ARRL Spread Spectrum Source Book** From a deceptively simple beginning, a group of experimenters set out to develop first theoretical and later practical systems for spread spectrum communications. This book consists of articles, papers and government reports that document the process whereby amateur spread spectrum progressed from the drawing board to the airwaves. $20.00

AR3851 **Hints and Kinks** Ideas for setting up your gear for comfortable efficient operation. $10.00

AR3185 **The Satellite Experimenter's Handbook** by Martin Davidoff K2UBC Expanded and revised. Focusing on satellites built by and for the international radio amateur community $20.00

AR4645 **Satellite Anthology** The latest information on OSCARx 9 throu 13 as well as the RS satelittes, the use of digital modes, tracking antennas, RUDAK, microcomputer, and more! $10.00

AR4483 **Weather Satellite Handbook** by Dr. Ralph Taggart WA8DQT. Expanded and revised to reflect today's weather-fax satellite technology. $20.00

AR4653 **Companion Software for Weather Satellite Handbook** 5-1/4" MS-DOS floppy $10.00

AR2973 **Complete DX'er** by Bob Locker W9KI Learn how to hunt DX and obtain hart-to-get QSL cards. $12.00

AR0402 **Solid State Design** Good basic information, circuit designs and applications; descriptions of receivers, transmitters, power supplies, and test equipment $15.00

AR4661 **ARRL's Antennas & Techniques for Low-Band DXing** can be your ticket to low-band success. $20.00

AR1996 **The ARRL 1996 Handbook** includes the latest innovations in ham radio, plus all the fundamental data. $38.00

Books for Beginners

TAB4354 **Beginner's Handbook of Amateur Radio** by Clay Laster W5ZPV. 395 pages. Wonderful book for newcomers. It is basic and well illustrated. Even if you have all the other ham handbooks, you'll still find this one useful. $22.00

W5GWNV **No-Code Video, Manual, Part 97 Rules** by Gordon West Learn how to be a ham radio operator $29.95

W5GWNC **Technician Class License Manual: New No-Code**–by Gordon West This book covers everything you need to become a Technician Class Ham. Every question and answer on the examination is found in this one book. FCC Form 610 application. $9.95

Antenna Books

UE220 **The Easy Wire Antenna Handbook** by Dave Ingram K4TWJ. All of the needed dimensions for a full range of easy to build and erect "sky wires." $9.95

WGP87034 **All About Cubical Quad Antennas** by William Orr and Stuart Cowan "The Classic" on Quad design, theory, construction, operation. New feed and matching systems. New data. $13.95

TAB3270P **Practical Antenna Handbook**–2nd edition by Jos. Carr. This 560-page book is a treasure. Starts with fundamentals, explains propagation of all kinds, and provides a ton of easy antenna projects. $26.95

WGP87077 **Simple, Low-Cost Wire Antennas For Radio Amateurs** by Willliam Orr and Stuart Cowan. Low-cost, multi-band antennas; inexpensive beams, "invisible" antennas for hams in "tough" locations. $13.95

Mobile or Chairside HT Holder

A simple, practical project based on a boat accessory.

Peter L. Barker XF1/KB6ASH
La Jolla de Los Cabos AB-506
San Jose del Cabo
B.C.S. 23400 Mexico

My other hobby besides amateur radio is sailing. As with ham radio, many "cute" products are developed for that market. One of the best-known is an ashtray mounted on a small beanbag so that it can be safely used on a boat in motion. I was looking at this one day and it occurred to me that this simple idea could be applied to a holder for an HT on board, in the car, or even by the favorite chair at home. Like many simple ideas, creeping elegance set in and the project soon started to mushroom into a universal holder. Eventually common sense prevailed and I came up with the idea described here. Even if you don't have a wife who is a talented seamstress, as I do, this project should be within the capability of any determined "putterer."

Make a simple bracket in the shape of an acute-angled "L" from aluminum, Plexiglas™ or thin plywood. Choose the size and angle to suit the radio and the desired operating position. The length of the foot of the "L" should be at least half the length of the long side.

The "beanbag" can be made of almost any material or fabric that is not slippery. The "beans" (or in my case, sand) are poured into a locking plastic bag and slipped into the beanbag. The bottom of the "L" is inserted into a pocket sewn onto the outside of the top layer of the bag. The bag is then folded over to sit with the weight of its contents resting on the foot of the "L." If the material used to form the "L" proves to be too slippery to allow the belt clip to hold the HT securely, a piece of thin rubber, such as inner tubing, or fabric can be glued on with contact cement to provide added friction. Alternatively, an elastic band can be slipped over the "L" and the radio.

I have used this simple support successfully on a heeling sailboat, in a bouncing Bronco (Ford type!), and next to my TV chair.

Oh, the creeping elegance... pocket for speaker mike and spare battery pack, a dual-radio model, Velcro™ closures, cable strain relief, etc.

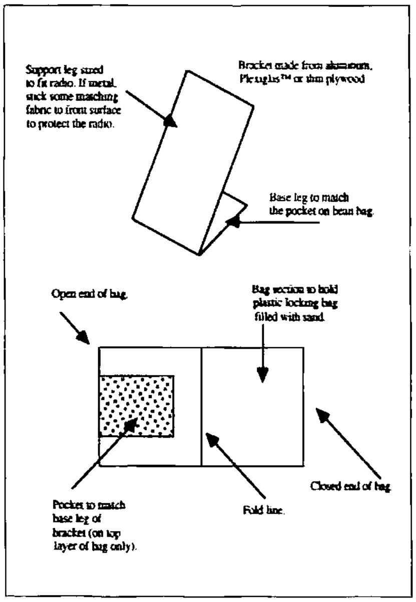

Fig. 1. Beanbag mobile HT holder. A) Bracket. B) "Beanbag," made of denim or light canvas.

PROPAGATION

Number 87 on your Feedback card

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

Radio propagation on the HF bands this month suffers from seasonal lows combined with low solar flux values near the bottom of sunspot cycle 22, although there is hope for substantial improvement during 1997. In general, QRN will be low and the bands quiet.

The best days are expected to be the 2nd–5th, 9th–12th, and 14th–17th. The worst days are expected to be 6th–8th, 18th–23rd, and 27th–29th. Use the accompanying calendar to guide your operations. There may be some intensive geophysical effects felt on or around the 20th and 21st, possibly ionosphere/atmosphere-related, earth-related, or both. Stay alert and prepared.

29 P-F	30 F	31 F-G				

10–12 meters

A few possible daytime F2 layer openings to South and Central America on the Good (G) days.

15–17 meters

Fair DX openings on Good (G) days between noon and sunset, and short-skip openings during the daylight hours. The band dies at sunset.

20 meters

DX to most areas of the world during daylight hours, peaking a few hours after sunrise and again during the early afternoon. Although the band usually closes soon after sunset, you may find occasional openings to South America and Antarctica until midnight. Daylight short skip from several hundred to 2,000 miles or so possible on most Good (G) or Fair (F) days.

30 meters

DX toward the Europe in the late afternoon and evening on Good (G) days until midnight, and then toward the Orient in the early sunrise hours. Possible long-path DX in the morning and also short skip most days out to a thousand miles or more, and farther in the evening.

40 meters

DX toward Europe and Africa in late afternoon hours, toward South and Central America around sunset, and good openings to the West and South Pacific peaking around sunrise on Good (G) days. Expect daytime short skip to 1,000 miles, and 2,000 miles at night.

80–160 meters

Both are excellent bands for DX during hours of darkness, peaking at midnight and just before dawn. Daytime skip on 160 is nonexistent, but on 80 it can be up to 500 miles, and over 2,000 miles at night. On 160, short skip can reach from 1,000–2,500 miles at night. Experts prefer vertical polarization for transmitting antennas (low-angle signal take-off) and horizontal polarization for receiving antennas (less noise) on 160 meters.

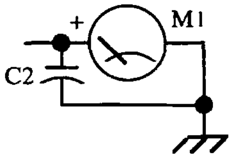
Don't forget to listen—even on the worst days—as you may be pleasantly surprised; also, now and then CQ into a seemingly "dead" band for the same reason. W1XU. 73

UPDATES

Speaking Frank-ly about corrections...

"A Versatile QRP Random-Wire Antenna Tuner," Oct. '96, page 21: In the sixth paragraph in the first column, a line reads "... from wiper terminal 1 of S1..." It should read "... from wiper terminal of S1..."

Fig. 1 on page 19 seems to have been cut off (just like the tops of my family's heads when I take vacation photos). This is the ground that was missing:

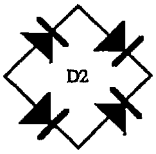


And please check the Parts List; there are two corrections to be made to it. The first is that the "Toroid FT50 43 (L1)" listing should be deleted because it is redundant. Secondly (and lastly), please pencil in a 3 in the T1 listing so that it reads, "6 turns AWG-22 on FT37-43 core (see text)."

Once again, our apologies to Mr. Brumbaugh.

An economical high current mistake.

Fig. 4 of "Economical High Current Power Supply" on page 52 of June's issue contained a full wave bridge labeled D2. Half of it is backwards. Here's how D2 should look:

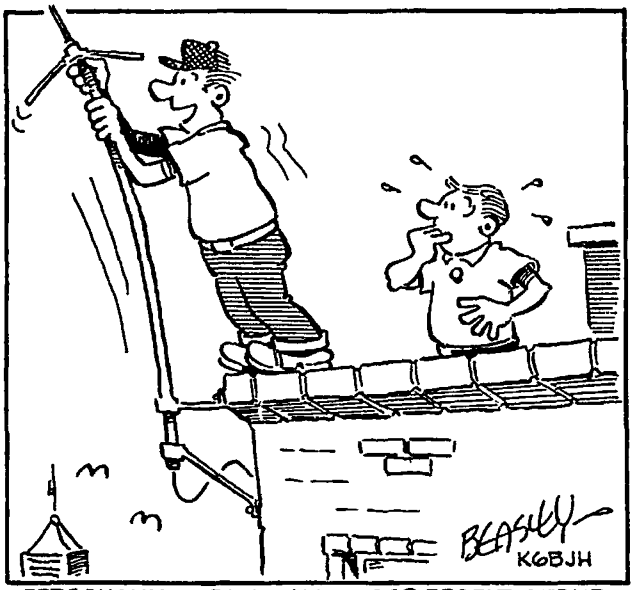


73

→ How you can get the ham gift(s) you've always wanted ... and didn't know how to ask for:

Circle this arrow!

1. Read this issue cover to cover (including all the ads).
2. Circle the item(s) you wish you had in your ham shack.
3. Show this marked issue (turned here with arrow circled) to your gift-for-you-buyer (who will actually welcome your subtle suggestions as they don't need the frustration from wasting time and money getting you something you don't really want when it's so easy to make you happy).



PERSONALLY, I THINK ALL THOSE PEOPLE AFRAID OF HEIGHTS ARE JUST PLAIN COWARDS!
